Elementary Manual on Applied Mechanics. By Prof. Jamieson. (London: C. Griffin and Co., Limited, 1892.)

THIS is the latest addition to the series of books introduced by Prof. Jamieson during the last few years. Like his useful work on the Steam Engine, it is the outcome of the course of lectures which he delivers to his own students. It is replete with the many mechanical contrivances to be found in the workshop, one chapter being devoted to the consideration of the screw-cutting lathe alone.

The illustrations, with which the book abounds, and the necessary descriptions of the various machines considered, are all that one may wish for.

An excellent feature of the book will be found in the manner in which, after having enunciated a principle, the author has applied it to some well-chosen examples. In this direction he has proceeded to an extent which will be highly appreciated by the student. Further, he has availed himself of any opportunity to obtain results experimentally, and these form a very instructive series of examples for the young engineer.

A careful perusal will show that the author considers it desirable that all matters pertaining to units, definitions, symbols, &c., should be carefully attended to But in his treatment of these he has not been entirely successful.

Take, for instance, his definition of the moment of a force on p 15 —"The moment of a force is equal to the force multiplied by the perpendicular distance from a point on its line of action" This is rather ambiguous, and we should prefer to see the words, *with respect to a point*, included in the definition

In a footnote, p 214, objection is taken to f being used for acceleration, since it "naturally represents a force" Then why use e for strain in the formula $e = \frac{l}{L}$, where e just as naturally represents an elongation, and strain is not an elongation, as the author clearly shows in another footnote on p 232?

Again, in a footnote on p 2 we have "$M = \frac{W}{g}$, where M stands for the mass, W for the weight in pounds, and g for the acceleration of gravity"

Now on p 215 the reader is asked to accept as correct the formula for centrifugal force, $P = \frac{Wv^2}{gr}$ lbs, but (continues the author) since $M = \frac{W}{g}$, then $P = \frac{Mv^2}{r}$ poundals Why should this substitution produce the change from pounds to poundals? We fail to see what is gained by having an ellipse for the figure representing motion in a circle

There is a want of consistency when an acceleration is spoken of as "a feet per sec in one second" in one place, and as "a feet per sec." on p 219 On the same page, too, $\frac{Wv^2}{2a}$ should evidently be read as $\frac{Wv^2}{2g}$

The examples worked out in the chapter on bending moments will show the student how to apply the principle of moments to the case of a beam loaded in any given manner. This is preferable to merely using a set of formula, a system attended with most disastrous results.

At the end of each chapter will be found a good selection of examples on the matter considered therein. We are informed that another volume dealing with the more advanced portions of the subject is in the course of preparation. G A B

OUR BOOK SHELF.

Man and the Glacial Period By G. Frederick Wright, D.D., LL.D, F.G S.A. (London Kegan Paul, Trench, Trübner and Co, 1892)

THE title of this book raises expectations which the contents fail to satisfy Out of 374 pages only sixty are devoted to the consideration of "the relics of man in the Glacial Period," and the treatment of the subject is, to say the least, uncritical. The reader does not learn from Prof. Wright that strong doubt has been expressed as to whether some of the "finds" of human relics in North America were really made in undisturbed glacial deposits, while his discussion of the European evidence is crude and inadequate, not to say misleading The author has apparently only a slight acquaintance with the literature of the subject, acquired chiefly from such recondite sources as Lyell's "Antiquity of Man," and treatises on general geology Of the many interesting facts bearing on man's relation to the Ice Age which have been discovered since those works were published our author is apparently ignorant Nor has "a summer spent in Europe" sufficed, as who could expect that it should, to make up for his other deficiencies Fortunately, the major portion of his volume deals with the glacial phenomena of North America, for here he is on safer ground We feel sure, however, that many of his statements and conclusions will receive scant support from geologists across the water. It would be interesting to know, for example, what evidence can be adduced to show that the southern part of the United States was submerged during the Glacial Period to the extent of 500 feet, so as to bring the waters of the Gulf of Mexico into Illinois and Indiana Again, we were under the impression that the author's "Ohio Lake," which he supposes came into existence when the great ice-sheet advanced into that region, had been effectually disposed of by Mr Leverett and Prof. Chamberlin Throughout the book the unity of the glacial period is confidently upheld, a view which Prof Wright is, of course, entitled to maintain, but he might have informed his readers that with few exceptions American geologists are quite of another opinion. He fails to understand the evidence adduced by Chamberlin and others in favour of the periodicity of glaciation, while so far as one can gather from his pages, he seems to know nothing of the facts bearing on this question which geologists in Europe have accumulated, especially during the past few years

Altogether we much prefer the author's earlier work, "The Ice Age in North America," of which the present is more or less of an abstract In the former the facts of American glacial geology were given in considerable detail, and the writer's crude speculations and hypotheses were less obtrusive. Should the present work come to a second edition we would advise Dr Wright to get some scientific friend to assist him in its revision Loose unscientific phraseology and incorrect definitions are of not infrequent occurrence throughout the volume Thus we read of "glacial ice," of "beautiful crystals of porphyry," &c, and are told that névé is the "motionless part" of a glacier, although a little further on we learn that it is from this "motionless" névé that "the glacier gets both its supply of ice and the impulse which gives it its first motion" Obviously Dr Wright is unacquainted with the observations of MM Pfaff, Klocke, and Koch on the movement of névé, while he might increase his knowledge of glacier motion by studying what Messrs. McConnel and Kidd have to say upon that interesting subject

Beetles, Butterflies, Moths, and other Insects By A W. Kapple and W. Egmont Kirby (London: Cassell and Co, 1892)

THIS work is a slight sketch of the more prominent British insects, intended for youthful and very inexperienced entomologists. The first section is devoted to classification, the key to the orders of insects being a fairly workable one, though it takes no account of the very numerous exceptions. Then follows a section on structure, in which when describing the eye the authors ignore the latest experiments on the subject, proving that the compound eyes form but a single image of the object seen; they also treat the tongue or proboscis as if it were homologous throughout the orders, whilst in lepidoptera it is developed from entirely different organs from what it is in the others, except in the very lowest family; and again when describing the legs they fall into the almost incredible error of speaking of the first joint as the trochanter, saying it is joined to the thorax by a hinge-

plate, the coxa, the first joint being in fact the coxa and the trochanter, the short joint articulating it to the femur Then follow short sections on the metamorphoses of insects and their habits and haunts, and longer sections on the collecting and preserving of perfect insects and larvæ, which are far more correct than the preceding ones, though very slight and quite insufficient for the initiation of a beginner The main part of the book is devoted to short descriptions of the more prominent British insects under their various orders and families, and illustrated by twelve coloured plates, which are decidedly good for cheap chromographic work, this is by far the most useful portion of the book, and well-marked forms will easily be recognized from the figures and descriptions, even though many species are placed in their wrong families

Ostwald's Klassiker der Exakten Wissenschaften Nos 31-37 (Leipzig Wilhelm Engelmann, 1892)

WE have already called attention to this admirable series of small volumes It consists of scientific papers which may be said to have marked definite stages in the development of science The only fault we have to find with the series, as we have already stated, is that only the German papers are given in the language in which they were originally written All the others are translated This is undoubtedly a mistake, for much may often depend on the precise words used by a great master of research In other respects the series is excellent, and should be of genuine service to scientific students The papers reproduced in the present set of volumes are Lambert's "Photometrie," three volumes (1760), photo-chemical researches, by R Bunsen and H E Roscoe (1855-59), an attempt to find the definite and simple conditions in accordance with which the constituent parts of inorganic nature are connected with one another, by Jacob Berzelius (1811-12), on a general principle of the mathematical theory of induced electrical currents, by Franz Neumann (1847), observations on the moving power of fire and the machines fitted for the development of this force, by S Carnot (1824)

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

"Aminol, a True Disinfectant"

WILL you grant me space, in order to avoid misunderstanding, to make the following explanation?—

(1) I recently learned that certain samples marked "Aminol, a true disinfectant" have been sent to various gentlemen, accompanied by a leaflet, in which my name, without my authority, is associated with those samples. Allow me to inform your readers that those samples contain "aminol" in water in the strength of one in five thousand Now, the experiments which I carried out with "aminol," as regards its disinfecting power of microbes, were made with a solution of the strength of one in six hundred, and the disinfecting power of this strength was the following spores of *Anthrax bacilli* remained unaffected after eight hours' exposure, only after an exposure for twenty-four hours did the number of living spores decrease, but some escaped disinfection even after so long an exposure. *Anthrax bacilli*, *Staphylococcus aureus*, and others were destroyed, but only after a prolonged exposure.

(2) A substance is advertised and circulated under the name of "Periodate crystals," and is associated with my name without my authority. Until quite recently I have made no experiments with it. A few years ago I made a few experiments, merely of a tentative character, with a solution which was labelled "Periodate," but not with the substance advertised as "Periodate crystals" With these latter I have recently made experiments, and I find that their solution in full strength has no disinfecting power on microbes, pathogenic and non-pathogenic, amongst which may be mentioned the bacillus and spores of anthrax, the bacillus of typhoid and of diphtheria, of cholera and of erysipelas, the *Bacillus prodigiosus*, the *Staphylococcus aureus*, and others Likewise I find that injection of large quantities of the solution into guinea pigs already infected with anthrax or diphtheria, has no power whatever in arresting or altering the normal course of these diseases to their fatal issue

E KLEIN

Tracery Imitation

I TOOK occasion some months ago to publish the result of observations on my child H 's progressive attempts at drawing after outline "copies" set before her.[1] Examination of the series of her drawings made almost daily during the period from her nineteenth to her twenty-seventh month showed in them no apparent form or shape They are simply vigorous pencil markings, answering as well to one "copy" as to another—or to none Quite suddenly, however, in her twenty eighth month, she seemed to catch the idea of breaking the "copy" (man) up into parts, and succeeded in making head, body, arms, legs, &c, in sufficient degree of relative proportion to show that here was, in her case, the rise of what I called in the article cited, "tracery imitation" of a visual picture

At that time I had no explanation to offer, but simply recorded the observation I have now, however, reached a way of explaining the rise of this apparently abrupt connection between muscle sense and sight—an explanation suggested to me by a passage in Stricker's argument for the eye-movement theory of the visual apprehension of figure or outline[2]

Before a child begins to acquire "tracery imitation," his drawings have no shape, but they show uniformly certain systems of angles, curves, &c, due to the easiest and most natural movements of the arm The eyes, however, have been in a measure already educated to recognize certain shapes or "copies" There are, therefore, in consciousness two series of associations—one of eye-movement sensations, a, a^1, a^2, a^3, a^4, &c, with a certain strength of revival, which we may call x the other, an associated series of arm-movement sensations, n, n^1, n^2, n^3, n^4, &c, representing a path of least resistance in arm movement Let us call its strength or degree of tendency to progressive revival y

Now, before the rise of "tracery imitation" y is greater than x, for the reason that the arm is restricted to a very few movements, and these are largely automatic Once start one of these movements, and the tendency to carry it out is very strong The tendency of the eye-movement series, on the contrary, to regular revival is slight, very few objects, copies, &c, being so clear and isolated as to give frequent unbroken reproductions Consequently, the arm-movement series, n, n^1, n^2, &c, wins the day, and an abortive "drawing" is the result

But the time comes soon when the reverse is true—when x is greater than y The eye-movement series gets strengthened constantly by the repeated exploration of familiar figures, especially if, as in the case of my child, the eye be trained by having the same "copies" set from day to day On the other hand, the arm and hand movement series gets constantly lesser and weaker, since the increasing mobility of the muscles, in the varied new activities of this period of infancy, is acquired at the direct expense of the early "cast iron" reactions which are largely organic. Both of these tendencies were very marked in H —the first, in the more pronounced recognition of the "copies" set before her; the second, in the less uncouth manner of holding her pencil, moving the fingers, disposing the arm, &c. Hence, it is simply a matter of education that x should soon overweigh y, and the elements of the eye series a, a^1, a^2, a^3, &c, should draw after them the arm series

An association thus begins to be formed between the several members of the a series and certain correct elements of arm sensation; these latter go to form, under this leading, a new n series, which gradually becomes independent as an acquisition. That each new tracery combination is thus learned separately is seen in the fact that after H. learned to trace certain "copies" (man, bird), she was yet entirely unable to trace any others.

[1] *Science*, New York, January 8, 1892

[2] "Du Langage et de la Musique" (French ed.), chap. xiii., see also his "Studien über die Association der Vorstellungen"

She was even unable to trace a circle, except as part of a man (the head)

In a paper presented at the London meeting of the International Congress for Experimental Psychology last August, I insisted that voluntary movements are possible in the child only after a great variety of motor "elements" have become available through great diffusion and mass in involuntary (imitative) reactions.[1] The above phenomenon, thus explained, serves to illustrate the broader position

As there is no literature on this subject, the question of "tracery imitation" has not even been put before, to my knowledge, I should be glad to have opinions upon it It is evident that if one hold the other theory of the visual apprehension of figure, *i e* that it is given by sight apart from sensations, of eye-movement, he could still hold the explanation which I have offered above, by substituting for the series of eye-movement sensations, a, a^1, a^2, &c , a series of visual sensations, v, v^1, v^1, &c J MARK BALDWIN

Difficulties of Pliocene Geology

CONSIDERING the very great importance which the later tertiary beds must occupy in all speculations about the origin of man and the present geographical distribution of plants and animals, it is unfortunate that they should have attracted so little attention among English geologists

The fact is perhaps not unnatural when we consider how very scantily they are represented in this country , the Norwich Crag being virtually the only bed where remains of pliocene land animals have occurred. The Norwich Crag is itself a very puzzling bed, where marine remains and land remains are found mixed together, the whole having been reassorted, and I do not know of a single pliocene land surface remaining intact in Britain The so-called forest-bed can no longer be classed as pliocene, but is clearly of pleistocene age. A real mark of the true pliocene horizon in Europe is the occurrence of the mastodon and its associated fauna

If we are to use the mastodon as a test we shall have to travel southward as far as Auvergne, if we are to find a pliocene land surface *in situ* Unfortunately Auvergne is a very dislocated and broken country, and the sequence of the later deposits is very hard to make out, and I much question whether it be possible to find sections showing the true reading of the beds in question nearer than Florence

I am writing in the hope that I may persuade Dr Forsyth Major, who knows the valley of the Arno so well, to communicate to NATURE some account of the results arrived at by the Italian geologists

At present the question is one of great perplexity Let me refer to two points First, How comes it that in no part of the world, so far as I know, has a single fragment of an undoubted pliocene beast been found in a cave? The carnivora of pliocene times must have frequented caves just as much as the bears and hyenas of pleistocene times, yet how comes it that we can nowhere find any tertiary remains in any cavern? It will not do to appeal to denudation, for if there be deposits anywhere protected from denudation it is those in caves. Can it be that every mountain chain where limestone rocks occur is younger than pliocene times?

Again, we know that in America, both north and south, the mastodon survived to the end of the Pleistocene age, and lived alongside of the mammoth and the Columbian elephant In Europe there is very great doubt whether the mastodon and any form of elephant were ever contemporaries. No doubt the teeth of the mastodon have been found with those of the elephant in the Crags, but the Crags have been so rearranged that it is impossible to draw any safe conclusions from them. It is at all events extraordinary that, according to the French geologists, the two beasts have never been found together in France I believe the same conclusion has been arrived at by the Italian geologists, but upon this point there is some uncertainty, and it would be very interesting to have the opinion of so competent an authority as Dr Forsyth Major upon the point It is one of importance, for upon it depends largely the question of whether there was a continuity in Europe between the pliocene and pleistocene land, or whether, as I am disposed to believe, there was a break between the two involving perhaps a violent revolution. There are other interesting questions involved in the issue I have raised, upon which you may possibly permit me to write on another occasion. Meanwhile the burden of my present letter is to point out how little we really know about the pliocene land, and how useful it would be to know more HENRY H HOWORTH

The Athenæum Club, December 5

Meteors

A FINE meteoric shower was observed here on the night of November 23, from 7h 30m to 12h 30m , when the observations were interrupted by cloud[1] The meteors were evidently "Bielids," the radiant at 8 30 being near a point, R A , 1h 20m , Dec , 40° 30′ The radiant, however, was not well defined, its area being at least 4° in diameter For a single observer, in a position which commanded only about one-sixth of the visible hemisphere, the meteors numbered about six a minute, which would indicate at least seventy-five a minute for the entire sky, exhaustively observed

At ten o'clock two observers, standing back to back in an open space, counted 104 meteors in five minutes , the position of the radiant being then, R A , 1h 30m , Dec., 41° 30′ —very near Upsilon Andromedæ At this time the radiant seemed to be rather more definite than earlier, and several nearly stationary meteors determined the place with reasonable precision

An hour later a similar count by the same two observers gave 100 meteors in four minutes and a half, and the radiant was determined at R A , 1h 40m , Dec , 40° The rate of frequency continued about the same until the sky clouded up an hour later, and must, I think be estimated as high as from 80 to 100 a minute for the whole number that might have been seen by a sufficient corps of observers This would foot up from 24,000 to 30,000 for the five hours

I am not quite certain whether the apparent change in the position of the radiant is, or is not, real , but a motion very similar in amount and direction is given by Denza in his observations of the meteoric shower of 1885 (see NATURE, vol xxxiii page 151)

Comet "*f*" (Holmes's) was about 10° west and 4° south of the mean radiant at R A , 0h 40m , Dec , 36° 45′. It was barely visible to the naked eye

Most of the meteors were very small, not exceeding the fifth magnitude , but a few, perhaps one in ten, were above the second, and in the course of the night four were seen which rivalled or surpassed Jupiter The brighter ones left bluish trains, which remained visible for three or four seconds The smaller ones often came in "flights" of three or four together, and fully half the paths were more or less curved and wavy from the resistance of the air

It is worthy of notice that the heliocentric longitude of the earth at the time of the shower was about 62°, instead of 65° which was the longitude of the descending node of Biela's orbit at the last appearance of the comet in 1852, and was the longitude of the earth at the time of the showers of 1872 and 1885 The fact suggests the inquiry whether perturbations since 1885 will fairly account for such a recession of the node

It is obvious also that if the meteoric swarms encountered by the earth in 1872 and 1885 were really moving in the orbit of Biela's comet (which at its last appearance had a period of 6·6 years), then the swarm encountered the other night, just seven years later, must have been an entirely different one—unless indeed the perturbations since 1885 can account for a retardation of nearly five months.

Last night was for the most part overcast, but a watch of fifteen minutes through occasional openings in the clouds showed only one or two possible Bielids. Evidently the shower was not continuing with any intensity. C A YOUNG

Princeton, N.J., U S , November 25

[1] Our "Eastern standard time" is just five hours slower than Greenwich time

Comparative Sunshine.

AFTER explaining that by "sunshine" I intend that which *would* fall upon the earth if there were no atmospheric obstruction, one must first notice the very elementary truth that the amount of such sunshine at any assumed time and place is in proportion to the altitude of the sun at noon, and also the

length of the day. Except at the time of the equinox, the gradual lengthening or shortening of the day, as the solstice is approached, most materially affects, especially in the higher latitudes, the total amount of sunshine received in twenty four hours.

But are there any convenient and readily accessible tables—as there easily might be—which would at a glance show numerically the comparative amounts of sunshine at certain selected times and places? I would wish to see such tables, say, for every tenth day, for the three months from an equinox to a solstice, for about every third degree of latitude in each hemisphere. I see not how, without this, either the causes or the effects of meteorological changes in different regions at different seasons can be justly estimated. I would propose to express the amount of sunshine during twelve hours at the equator at the equinox by, say, 100, the figures rising above this, or falling below it. Thus there would be more than 100 given for the latitude of the Tropic of Cancer at the summer solstice, with a vertical sun and more than twenty four hours' sunshine, with 100 for a latitude still further north. REGINALD COURTENAY

The Imperial Hotel, Sliema, Malta, November 14.

Quaternions

By the kindness of the author I have just received a copy of Mr. Heaviside's paper "On the Forces, Stresses, and Fluxes of Energy in the Electromagnetic Field" (*Phil. Trans.*, 1892, p. 423), in which he reopens a question debated in your columns some time ago—the question of Quaternions *versus* other methods of vector analysis for the use of physicists.

At present the matter stands thus:—There are two widely known systems of vector analysis before the public—Quaternions and the Ausdehnungslehre—and quite a multitude of less known ones, of which Prof. Gibbs's seems to be one of the least open to objection, and of which, in my opinion, Mr. Heaviside's is by no means so. It would take too long, however, to justify this opinion, but I wish to make an appeal to Mr. Heaviside and Prof. Gibbs on grounds independent of the merits or demerits of their particular systems.

Of the Ausdehnungslehre I do not feel competent to speak. As to Quaternions, there are undoubtedly some inconveniences in physical applications, and I am quite willing to concede that a grave one is the very frequent use of the letters S and V (Mr. Heaviside uses the latter). I do not regard the sign of the scalar product which vexes the soul of Mr. Heaviside as of any consequence. But while thus admitting that a better system than Quaternions is conceivable, I think I can show that the position of the dissenters is little short of suicidal.

The band of physicists who use and urge the use on others of vector analysis is woefully small. Let me put a question to two of the justly best known of that band, Prof. Gibbs and Mr. Heaviside. What is the *first* duty of the physical vector analyst *qua* physical vector analyst? I think I may anticipate that the answer will be—to convince the world of mathematical physicists that vector analysis must be unshelved and set to work. The next question that arises is one of tactics. What should be the plan of campaign to bring this desirable result about? Here I am afraid we cannot hope for unanimity even among the members of the small band, and this is to be most grievously deplored. But surely every sane man will agree that what most certainly the analysts should not do is to present their arguments to those they would convince in a dozen different mathematical languages, each of which is puzzling enough to those learned in allied languages. Grant this, and it follows that Quaternions and the Ausdehnungslehre should be left in sole possession of the field. The day for Prof. Gibbs's improvements is not yet. Prof. Gibbs and Mr. Heaviside have not yet convinced the rest of the small band—not to say each other—of the merits of their algorithms. Let me implore them to sink the individual in the common cause, and content themselves with the faith that posterity will do them justice.

Apart from the question of notation there seem to be two schools of opinion as to the proper conduct of the campaign. To vary the metaphor, Maxwell, Clifford, Gibbs, Fitzgerald, Heaviside prescribe a course of spoon-feeding the physical public. Hamilton and Tait recommend and provide strong meat. I do not think that harm, but rather good, will come from this double treatment, as one course will suit some patients and the other others. *But* let the spoon feeders provide nourishment of the same *kind* as the other physicians. Is not Maxwell, Clifford, and Fitzgerald's food as digestible as Prof. Gibbs's and Mr. Heaviside's? ALEX. MCAULAY

Ormond College, Melbourne, October 31.

Animals' Rights

MR. SALT disputes the justice of the statement that he has given two contradictory definitions of animals' rights, inasmuch as, according to him, that which he has set forth on p. 28 is but a repetition and amplification of the one to be found on p. 9.

By the definition on p. 9 animals' rights are said to consist in a "due measure" of the restricted freedom which constitutes the right of man, *i.e.* (as Mr. Salt notes) the freedom "to do that which he wills, provided he infringe not the equal liberty of any other man"—"a restricted freedom" which guarantees to the harmless individual *the security of his life and liberty*.

But on p. 28 the rights of animals (which were said before to consist in a "due measure" of that just quoted) being here stated to be "subject to the limitations imposed by the permanent needs and interests of the community," are found to be burdened with so serious a qualification that *security for the life and liberty of the harmless individual is by it completely destroyed*.

A European might settle with confidence in an unknown island, on the assurance that he would be allowed a measure of the general right of the natives to the freedom to do that which they would, provided they infringed not the equal rights of any other, but were he afterwards to discover that the "measure" of this right which was considered to be the "due" of a foreigner was in reality limited "by the needs and interests of the community," and that, a community where the custom of enslaving and eating strangers had existed from time immemorial, we venture to assert that his departure from the island would be effected with as little delay as possible. We should much regret misrepresenting Mr. Salt's statements, but the assertion that the second definition of rights is but a repetition and amplification of the first is manifestly untenable, and if, by "*due measure*" for animals of the rights of man, Mr. Salt would have us understand that he meant—only such a measure as is consistent with the nullification of the most fundamental privileges secured by them, he must have been discussing the subject in a vein of sarcasm which we are bound to confess we had quite failed to appreciate.

THE REVIEWER.

The Height and Spectrum of Auroras

THERE was a magnificent aurora on the evening of the 4th, part of which, from 10h. 46½m. to 48m. or 49m., was an intense red. I noted the positions of some of the features at the exact half hours and also at some other times, for comparison with any observations that may have been made in other places, for ascertaining the height of the phenomenon; and I hope some such observations have been made of the recent display, and will be made of further ones in the future, for Dr. Veeder, of Lyons (New York), has kindly consented to calculate the heights from the observations.

I am surprised that none of our persevering photographers have as yet obtained a good photograph of the auroral spectrum. I do not think it would be more difficult than the stellar photographs that have been taken, seeing that the exposure might go on for hours. It would be desirable to have it done with a camera that could be pointed in any direction at will, so that wherever the observer saw a bright portion of the aurora he could direct the instrument to it. T. W. BACKHOUSE.

The Teaching of Botany

THERE appeared in NATURE (vol. xxxi. p. 229) a paper entitled "Experiments suitable for illustrating Elementary Instruction in Chemistry," by Sir H. E. Roscoe and W. J. Russell. I have long felt the want of a similar series of experiments in physiological botany. There is not much difficulty in teaching the morphological side of the subject, but it is not easy for the ordinary high-school teacher to devise and carry out a suitable series of experiments for demonstrating the more important aspects of physiological botany. If some master in the

subject would do for botany what Sir H E Roscoe has done for chemistry he would confer a great boon on teachers and young students A H

Egyptian Figs.

MY attention has been called to a very obvious slip of the pen in my note on Egyptian Figs, in that I have written "Pliny" instead of "Theophrastus" The former, as all know, was a *Latin* author, but he simply copies from the latter Having both authors before me at the time, I accidentally put one name for the others The refs. are as follows —Theoph iv 2, Dioscor I I, Plin xlii 7 GEORGE HENSLOW

I CANNOT understand how, when writing on this subject *ante*, p 101), I overlooked the circumstance that the ancient boulder-beds of Australia, India, and South Africa received full notice in Prof J Prestwich's "Geology," vol ii pp 143 146

December 9 W T BLANFORD

SCHEELE

DURING this month Sweden commemorates the one hundred and fiftieth anniversary of the birth of one who has conferred an imperishable lustre on her annals Carl Wilhelm Scheele—although a German by nationality, for he was born at Stralsund, the capital of Pomerania—spent practically the whole of his short life in Sweden, and is usually regarded as a Swede The son of a tradesman, Joachim Christian Scheele, and the seventh child of a family of eleven, Scheele, as a boy, gave little promise of the genius and power which astonished the scientific world towards the close of the last century It is perhaps indicative of a certain mental imperfection that he should have been wholly incapable of learning a foreign language, although he lived in Sweden during more than half his life his knowledge of Swedish was so imperfect that his memoirs, addressed to the Academies of Stockholm and Upsala, were invariably written by him in German and had to be translated by others before publication By what influences he was led to the study of chemistry is unknown There was nothing apparently in his home life, or in the mode or circumstances of his education to direct his inclination towards science As a boy he began the study of pharmacy, and at his own wish was apprenticed to an apothecary at Göteborg named Bauch, with whom he remained eight years Here he had access to the standard treatises on chemistry of that time, and he devoted all his leisure, often working far into the night, to the study of the works of Neumann, Lemery, Kunkel, and Stahl Kunkel's Laboratorium was, indeed, his chief instructor in practical chemistry, and it was by diligently repeating, in the first instance, the experiments contained in that book that he acquired that extraordinary manipulative skill and analytical dexterity on which his success as an investigator ultimately rested

When twenty-three years of age Scheele removed to Malmö, and some years afterwards to Stockholm, where he superintended the shop of an apothecary named Scharenberg It was about this time that his career as a discoverer began, by the isolation of tartaric acid from cream of tartar. He ascertained many of the characteristic properties of this acid and prepared and examined a number of tartrates These early efforts met, however, with a somewhat untoward reception. It seems that Scheele drew up an account of his observations and forwarded it to Bergman, who then filled the chair of chemistry in the University of Upsala as the successor of Wallerius. Bergman failed to appreciate the significance of the work of the young and unknown apothecary and by some mischance the manuscript was lost. The importance of the discovery was, however, recognized by Retzius, who induced Scheele to write a second account of his work and to submit it to the Academy of Sciences at Stockholm, by whom it was eventually printed In 1771 Scheele published his memorable essay, "On Fluor Mineral and its Acid," in which he first demonstrated the true composition of fluorspar, showing that it "consists principally of calcareous earth saturated with a peculiar acid," named by him "fluor-acid" Although he found that the "fluor-acid" (hydrofluoric acid) dissolved "siliceous earth," he failed to recognize the change thereby produced in the "fluor-acid" and was thus led to an erroneous conception of its real nature He was in fact led astray by the circumstance that his experiments were for the most part made in glass vessels, and hence the fluor-acid was contaminated with more or less silica and hydrofluosilicic acid The origin of the silica in the acid prepared by Scheele was first clearly indicated independently by Wiegleb and Meyer In 1773 Scheele went to Upsala as pharmaceutical assistant to Mr Lokk, in whose shop he chanced to meet the chemist Gahn Lokk and Gahn were speculating on the cause of the different mode of action of distilled vinegar on nitre before and after fusion This was explained by the young assistant, who pointed out the nature of the change effected on nitre by fusion, and the fact that it is converted into a salt (potassium nitrite) from which a peculiar acid, different from true "spirit of nitre," can be obtained by treatment with distilled vinegar Gahn, struck with the sagacity of the young pharmacist, offered to introduce him to Bergman The invitation was at first declined, Scheele had not forgotten the unfortunate incident of the tartaric acid memoir Eventually he allowed himself to be convinced that Bergman's action was due more to inadvertence than to indifference, and the acquaintance which followed rapidly ripened into a strong friendship In 1774 Scheele, at the suggestion of Bergman, published his well-known memoir "On Manganese, Manganesium, or Magnesia Vitrariarum" This essay, although marred and in part obscured by the phlogistic conceptions of the period, will for ever remain one of the classics of chemistry In it Scheele not only established the nature of "pyrolusite" or "wad," but, in studying the action of acids upon the mineral, he was led to the discovery of baryta and of chlorine, the properties of which he minutely describes. In 1775 appeared his memoir on arsenic acid which he prepared in several ways; he discovered many of the more striking properties of this body and obtained a number of its salts In the course of the investigation he discovered arseniureted hydrogen, and the well-known pigment Scheele's Green In the same year he published his essay on benzoic acid, the "flowers of benzoin" of the apothecary After a stay of two years in Upsala Scheele was appointed by the Medical College *provisor* of the pharmacy at Köping, a small town on the north shore of Lake Malar Instead of the prosperous business he had been led to expect he found nothing but discomfort and disorder, and the remainder of his life was spent in a constant struggle with privation and debt, relieved at length, to some extent, by a grant, at Bergman's instigation, from the Stockholm Academy. Of this money Scheele set aside one-sixth for his personal necessities, and devoted the remainder to his researches. In 1777 he took over the business of the pharmacy from the widow of the former proprietor, but it was only by unremitting industry that he was able to discharge the obligation he thereby incurred Not a year passed, however, without Scheele publishing two or three memoirs, every one of which contained a discovery calculated to enhance his reputation as the greatest experimenter of his time This untiring devotion to science at length began to tell upon a frame constitutionally weak and doubtless further enfeebled by privation, and by the worry

of debt and difficulties He struggled on, however, a martyr to rheumatism and suffering from a complication of internal disorders until he was struck down in the spring of 1786 Some time before his fatal illness he had formed the resolution of marrying the widow of his predecessor so soon as his circumstances should permit on his death-bed he carried out this project, bequeathing to his wife such property as he had been able to acquire Two days afterwards (May 21, 1786) he died at the age of forty-four

The eleven years during which Scheele lived at Koping were fruitful in investigations of the highest importance in every department of chemistry In that time he discovered molybdic, tungstic, and arsenic acids among the inorganic acids, and lactic, gallic, oxalic, citric, malic, mucic, and uric among the organic acids He also discovered glycerin, determined the nature of Prussian blue, and prepared hydrocyanic acid He demonstrated that plumbago is nothing but carbon associated with more or less iron, and that the black powder left on the solution of cast-iron in mineral acids is essentially the same substance He determined the chemical nature of sulphuretted hydrogen, discovered arseniureted hydrogen, and invented new processes for preparing ether, powder of algaroth, calomel, and *magnesia alba* He made numerous analyses of air by absorbing the oxygen with a mixture of iron filings and sulphur He concluded that "our atmosphere contains always, though with some little difference, the same quantity of pure or fire air [oxygen] viz $\frac{9}{33}$ which is a very remarkable fact, and to assign the cause of it seems difficult, as a quantity of pure air [oxygen] in supporting fire, daily enters into a new union, and a considerable quantity of it is likewise corrupted or changed into aerial acid (carbon dioxide) as well by plants as by respiration, another fresh proof of the great care of our Creator for all that lives"

Scheele's greatest work, however, is unquestionably his treatise on "Air and Fire," which appeared in 1777 with a preface by Bergman, who, according to Thomson, superintended its publication. This elaborate essay shows Scheele at his best and at his worst, it testifies to his genius as an experimentalist and to his weakness as a theorist No one can read this, or indeed any other of Scheele's memoirs, without being impressed by his extraordinary insight, which at times amounted almost to divination, and by the way in which he instinctively seizes on what is essential and steers his way among the rocks and shoals of contradictory or conflicting observations No man was ever more staunchly loyal to the facts of his experiments, however strongly these might tell against an antecedent or congenial hypothesis Had Scheele possessed that sense of quantitative accuracy which was the special characteristic of his contemporary Cavendish, his work on "Air and Fire" would inevitably have effected the overthrow of phlogistonism long before the advent of Lavoisier His memoir is essentially an essay on oxygen, of which he was an independent discoverer, in its relations to life and combustion. It is perhaps idle to speculate on the causes which prevented his clear recognition of the full truth It may have been that he was essentially a *préparateur* like Priestley, and that quantitative chemistry had few attractions for him, it is far more probable that the character of his work was determined by the circumstances of his position, by his poverty, his lack of apparatus, and his want of assistance As it is, it remains one of the most remarkable circumstances in the history of human knowledge that a man working under such adverse conditions in a small village on the shore of a Scandinavian lake should have been able to change the entire aspect of a science.

It was stated by Crell, the editor of the well-known *Neue Entdeckungen* and *Annalen*, in which many of Scheele's papers first appeared, that the great Swedish chemist was invited to this country with the offer of an easier and more lucrative position than that which he had at Köping, but that his partiality for Sweden and his love of quiet and retirement delayed his acceptance of the offer until a change in the English ministry put a stop to the negotiations Thomson, the author of the "History of Chemistry" in mentioning this circumstance, expresses his doubts as to its truth, and states that he made enquiries of Sir Joseph Banks, Cavendish, and Kirwan, but none of them had ever heard of such negotiation Indeed the circumstance is intrinsically improbable "I am utterly at a loss," says Thomson, "to conceive what one individual in any of the ministries of George III was either acquainted with the science of chemistry or at all interested in its progress What minister in Great Britian ever attempted to cherish the sciences, or to reward those who cultivate them with success? If any such project ever existed, it must have been an idea which struck some man of science that such a proposal to a man of Scheele's eminence would redound to the credit of the country But that such a project should have been broached by a British ministry, or by any man of great political influence, is an opinion that no person would adopt who has paid any attention to the history of Great Britain since the Revolution to the present time."

T. E THORPE

WERNER VON SIEMENS.

ERNST WERNER SIEMENS was the eldest son of Christian Ferdinand Siemens and Eleonore Deichmann, he was born in 1816 at Lenthe in Hanover, where his father was engaged in the business of agriculture and forestry

From his very childhood the subject of this memoir learnt the lessons of self control and responsibility, for owing to his mother's delicate health and his father's occupations, the care of his younger brothers and sisters devolved on himself and his sister Mathilde, in these younger days he also learnt tact, and his father taught him that difficulties had to be faced and overcome, and that duties must never be avoided

In 1823, a few months after the birth of his brother William (whose lamented death occurred here nine years ago), the family removed to Menzendorf near Lubeck, in the Grand Duchy of Mecklenburg In the Gymnasium of Lübeck Werner was educated up to his eighteenth year, when, by the advice of his father—who with rare prescience saw in Prussia the nucleus of German Unity and Empire—he went to Magdeburg to volunteer for service in the Prussian Army For three years he studied in the Military School of Berlin, and in 1838 received his commission as a lieutenant in the artillery, and returned to Magdeburg, he was soon transferred to the Technical Division of the Artillery at Spandau, and afterwards to Berlin.

In July, 1839, his mother died, and six months afterwards his father, and then, at only twenty-three years of age, he became the veritable guardian of his younger brothers and sisters.

In 1842 he took out a patent in Prussia for electroplating and gilding, and having established a factory in Berlin for putting his invention into practice, he urged his brother William to devote his attention to the subject This the younger brother did, and the story of his enterprise and success in this country then and ever since has been told by Dr William Pole in his most interesting biography of him, to this volume and to the works of Dr Werner von Siemens, the first volume of a translation of which has recently been published by Mr Murray, we are indebted for much of the information contained in this short notice

In 1844 the young artillery officer was appointed to the important post of Superintendent of the Artillery workshops, and in 1847 he became a member of the commission then instituted for introducing the electric telegraph into Prussia Next year his military duties called him to Kiel, where in conjunction with his brother in-law, Prof Himly, he protected that port against the attack of the Danish fleet, by means of submerged mines connected with the shore by cables, at once the precursor of the submarine cable and the torpedo In the summer of 1848, as commandant of Friederichsort, he built the fortifications for the protection of the harbour of Eckenförde, which afterwards became so celebrated In the same year he was recalled to Berlin in order to erect a line of telegraph from Berlin to Frankfort-on-the-Maine, the first electric line laid in Germany, and with this his official military career terminated, and he devoted his attention altogether to those scientific discoveries and

inventions which have made the name of Siemens a household word in every region of the globe.

In 1874 Dr Werner Siemens was elected a member of the Royal Academy of Sciences of Berlin, and the speech he made upon that occasion enables one to understand and appreciate his connexion with physical science He was professionally connected with the application of science, which unfortunately left him but little leisure for those purely scientific investigations to which he always felt specially attracted. He says, to quote his own words in the speech just referred to, "My problems were generally prescribed by the demands of my profession, because the filling up of scientific voids which I met with presented itself as a technical necessity. I will only here mention cursorily my method of measuring high velocities by means of electric sparks, the discovery of the electrostatic charge of telegraph conductors and its laws, the deduction of methods and formulæ for testing underground and submarine cables, as well as for determining the position of faults occurring in their insulation, my experimental observations on electrostatic induction, and the retardation of the electric current thereby, the conception and realization of a reproducible basis of measurement for electrical resistance, the proof of the heating of the dielectric of a condenser by sudden discharge, the discovery and explanation of the dynamo electric machine I think I may claim that many of my technical contributions are not without scientific value, among which I may mention the differential regulator, the manufacture of insulated conductors by pressing gutta-percha around them, telegraphic duplex, diplex, induction and automatic recording instruments, the ozone apparatus, and measuring instruments of different kinds I had the honour of seeing these recognized by receiving from the Berlin University the distinction of Doctor of Philosophy, *honoris causa*"

The reply to this speech was made on behalf of the Berlin Academy by Prof du Bois Reymond, the Secretary of the Physical and Mathematical Section, and some of the words he then spoke will show how Germany appreciated one of her ablest sons, one whom we also may claim, for when Werner Siemens was born, the King of England was Elector of Hanover "By appropriating such a scientific form as yours, my dear Siemens, no Academy need be untrue to the laws of its foundation Yours is the talent of mechanical discovery, which primitive people not improperly described as divine, and the cultivation of which constitutes the ascendancy of modern culture Without having yourself worked with your hands in practical mechanics, you have reached the highest point in that art as creating and organizing head With clear view and daring mind you soon grasped the great practical problems of electric telegraphy, and thus secured to Germany an advantage which Gauss, Wilhelm Weber, and Steinheil could not have procured for it Your labours were for electricity what Frauenhofer's were for light, and you are the James Watt of electro-magnetism. Now you rule over a world which you created. Your telegraph lines surround the globe Your cable ships navigate the ocean Under the tents of nomads using bows and arrows, through whose hunting grounds your messages pass, your name is mentioned with superstitious awe"

This poetical description is fully justified by the great undertakings that have been carried out by the Siemens firm The Indo-European telegraph, 2750 miles in length, passes across Europe, through a part of Russia to Tabreez and Teheran in Persia, and thence to India. But for the international character of the firm this work could probably never have been accomplished But with Mr Carl Siemens in St Petersburg, Dr Werner in Berlin, and Mr William in London, to carry out the necessary negotiations, the tender was accepted in June, 1869, and the work was completed in December of the same year Since then eighteen cables of a total length exceeding 21,000 miles have been constructed at their Woolwich works and laid in the Atlantic by the *Faraday*, by the firm of Messrs Siemens Brothers and Co, Limited, of which firm Dr Werner von Siemens was Chairman and Mr Alexander Siemens is the Director in London.

In a single line of the speech just alluded to Dr Werner refers to the dynamo machine On this machine the whole supply of electricity for lighting, transmission of power, and other large purposes is dependent; and it is interesting in this connexion to note that the only rival to the electric light for large effects is the regenerative gas lamp invented by Dr. Werner's youngest brother, Mr Frederick Siemens, the Inventor, with Sir William Siemens, of the regenerative gas furnace.

Dr. von Siemens was a Knight of the Prussian order *pour le mérite*, an honour conferred only on those who have been distinguished for their services to science and industry. The honorary degree conferred upon him by the University of Berlin, and his membership of the

Royal Academy of Sciences of Berlin, have already been referred to. Dr von Siemens was a member of many learned societies, and only in the spring of this year he was elected one of the sixteen honorary members of the Institution of Civil Engineers. The late Emperor Frederick III of Germany conferred upon him the patent of nobility in 1888, and the present Emperor has expressed his sympathy with his sorrowing widow and family.

Dr. Siemens was unfortunately one of those attacked during the influenza epidemic, and although he recovered from it, it left him weak, and he has since been ailing more than once. A work on which he has been spending his spare moments was an autobiography, giving reminiscences of himself and of the firm of Siemens and Halske. This was published in Berlin a fortnight ago. On Tuesday, the 6th inst., Dr Werner breathed his last at half-past six in the evening, just within a week of completing his seventy-sixth year. It may truly be said of him that although he has passed from us, his life's labours will ever endure, having left an indelible mark on the world's progress.

The funeral took place on Saturday. The London, Belfort, Vienna, and St Petersburg factories of the firm of which the deceased was a member, sent officials and workmen; the many thousands following the hearse, and the respectful attitude of the bystanders in the streets through which the funeral procession passed testifying to the regard in which he was held. The Emperor William was represented by Prince Leopold, the Empress Frederick by Count Seckendorff, and the German Empire by Chancellor Caprivi. Science and art and industry, the City of Berlin and the town of Charlottenburg were represented by deputies and deputations, all combining to do honour to one esteemed of all.

E. F. B.

NOTES

WE are glad to announce that Sir Archibald Geikie has undertaken to write the Life of Sir Andrew C. Ramsay, his predecessor in the Geological Survey. Sir Andrew Ramsay spent nearly the whole of his scientific career in the service, so that the record of his life and the story of the progress of the Survey are closely bound together. This is the third member of the staff of the Survey whose memoirs Sir Archibald Geikie will have written, the two others being Edward Forbes (whose Life he wrote in conjunction with the late Prof. George Wilson) and Sir Roderick Murchison. Sir Archibald joined the staff under Ramsay, and grew into the closest relations of friendship with him.

WE regret to have to record the death of Mr H. T. Stainton, F.R.S. He died on December 2 at the age of seventy. He was indefatigable in his study of entomology, to which he made many important contributions. His chief work is "Natural History of the Tineina," in four languages, with many plates. His "Manual of British Butterflies and Moths" is also well known. Mr. Stainton was one of the founders of the *Entomologists' Monthly Magazine*, and remained to the end of his life one of its editors. He was for many years secretary of the Ray Society and of the Zoological Record Association, and one of the secretaries of Section D of the British Association. From 1848 he was a Fellow of the Entomological Society, of which he was at one time president; and from 1859 he was a Fellow of the Linnean Society, of which he was at one time vice-president. He was elected a Fellow of the Royal Society in 1867.

THE Chemical Society held a special meeting on Tuesday, the anniversary of the death of Stas. A paper, prepared for the occasion by Prof. J. W. Mallet, F.R.S., on "Jean Servais Stas and the measurement of the relative masses of the atoms of the chemical elements," was read and discussed.

THE new Victoria buildings of University College, Liverpool, which include the Jubilee Tower, were formally opened on Tuesday. Lord Spencer, as Chancellor of the Victoria University, took part in the ceremony. At a banquet held in the evening, Mr. Bryce announced that the Queen, out of certain funds belonging to the Duchy of Lancaster, had been pleased to bestow upon the two great Lancashire Colleges a sum of £4000, to be applied in some permanent form, such as might be agreed upon by the authorities of the Colleges, particularly the principals, to commemorate the event of that day, and Her Majesty's interest in the growth of the institution.

ON Monday, at Merchant Taylors' Hall, Dr. William Anderson presented the prizes in connection with the City and Guilds of London Institute for the Advancement of Technical Education. Afterwards, addressing the students, Dr Anderson called attention to the extraordinary advantages enjoyed by students of the present day in comparison with those within the reach of students of the past generation. In nearly all towns men and women were improving their knowledge in almost every branch of art and science to which their necessities or their inclinations led them. He had come to the conclusion that the aids given nowadays to manufactures and commerce were absolutely indispensable if England was to hold her own, and to overcome the difficulties which high-priced labour, the restrictions of the Legislature, and the interference of trade organizations imposed.

DR T. JEFFREY PARKER, F.R.S., of Dunedin, Otago, New Zealand, who is now in this country, will read a paper on the cranial osteology, classification, and phylogeny of the Moas (Dinornithidæ) at the Zoological Society's meeting on the 14th of February.

THE committee appointed by the Board of Agriculture to inquire into the plague of field voles in Scotland have declined for the present to recommend the adoption of the plan lately carried out in Thessaly by Prof. Loeffler, who claims to have got rid of voles in that district by feeding them with prepared bait containing the germs of mouse typhus. It is thought that Prof. Loeffler may not have attached sufficient weight to other causes which have doubtless operated to reduce the swarms of voles in Thessaly, such as the heavy rains which on the low ground would flood the holes and runs of the mice. The chairman of the committee, Sir Herbert Maxwell, and the secretary, Mr. J. E. Harting, with the sanction of the Board of Agriculture and of the Treasury, are about to proceed to Thessaly for the purpose of taking evidence there and reporting.

A NEW edition of M. Alphonse Bertillon's important book on "Identification Anthropométrique" will be published in January. The book has been entirely recast and considerably enlarged. It is the result of ten years of observation, and has been prepared, not merely for the anthropometric service directed by the author, but for all who desire to have a proper comprehension of man's physical qualities. In addition to the copies intended for the use of the penal administration of the French Ministry of the Interior, a small number of copies will be reserved for persons who may desire to subscribe for them.

ON the evening of Thursday the 8th instant a deep barometric depression advanced upon our north-west coasts, and proceeded with considerable rapidity in a south-easterly direction, completely traversing Great Britain, as far as Dover, and travelling throughout its course at the rate of about 36 miles an hour. Its passage was accompanied by gales and by heavy rain or sleet, with severe snowstorms on the east coast. This disturbance passed away to the eastward, and was followed on Saturday by a fresh depression which appeared in the north-west, causing a strong gale in that district, and heavy squalls in most other parts. The changes of temperature were very

irregular, the air being warm and moist under the influence of the cyclonic systems, but cold and relatively drier in the rear of the disturbances, in Scotland the frost was at times severe, the lowest of the minima being as low as 8° in the east of Scotland. In the early part of the present week a temporary improvement took place, with a generally rising barometer and falling thermometer, but these conditions soon gave place to a fresh disturbance in the north-west, accompanied by south-westerly winds generally. The *Weekly Weather Report* for the period ending the 10th instant showed that the temperature was below the mean in all districts, the greatest deficiency being about 7° over the northern parts of the kingdom. Rainfall exceeded the mean in the north-west of England and the north of Ireland, but in all other districts it differed little from the average amount. Bright sunshine was more prevalent than for many weeks past, except in the north of Scotland, where only 5 per cent. of the possible amount was registered.

A Foreign Office "Report on the Social and Economical Condition of the Canary Islands" (No. 246, 1892) contains some details with respect to the climate. There is no record of the freezing point having been touched at Laguna (Teneriffe), 1840 feet above the sea. At Vila Flor, also in Teneriffe, 4335 feet above the sea, the highest point where cultivation exists, the lowest temperature recorded in 1890-91 was 28°, the lowest reading at the sea level during the same period was 49°. The highest summer reading at Laguna was 104°.9 in 1885. The average maximum temperature near the sea in the summer is about 82°. The annual rainfall at Laguna is 29.4 inches, but at Santa Cruz (Teneriffe), at the sea level, it is only about 11 inches, and at Las Palmas it is as low as 8.4 inches. The greater part of the rain falls in the Monte Verde, where the vapour is carried from the sea by the trade wind. The rain generally begins early in October and ceases early in May.

The country between the Nile and the Red Sea has not always been so barren as it is to-day. There is ample evidence that in former times bodies of cavalry from three to five hundred in number ranged without commissariat difficulties over districts which are now deserts. The Arabic names of the valleys are names for trees, and there can be little doubt that at one time the valleys abounded with the trees after which they were called. How is the change to be explained? Much light is thrown on the problem by a most interesting paper printed in the new number of the *Kew Bulletin*, to which it has been communicated by Mr. E. A. Floyer, F.L.S., Inspector-General of Egyptian Telegraphs. It is an extract from the report (which will be published in French by the Egyptian Government) of the expedition despatched by the Khedive to this region in 1891. The writer believes that the mischief has been done during the last twelve hundred years, and that it is to be attributed to the Arab and his camel; the camel having eaten the leaves and shoots of the trees, the Arab having converted into charcoal the stem, root, and branch. The writer is inclined to state the matter thus: So long as the valleys were all the Arab had to depend on for feeding his camels, so long he preserved his trees for his camels. But by degrees some Arabs got a footing in the Nile Valley. They hired their camels to the farmer to carry their harvest. They went back to their deserted valley and brought away the trees in form of charcoal. Thus the land was gradually made bare. If this explanation is correct—and there is evidently much to be said for it—the writer points out that a like cause may be invoked over large areas to explain, for example, the disappearance of the frankincense and spices from Southern Arabia, to explain the thousands of chariots and horsemen in Palestine, and to explain how in early times a greater fertility and population existed in many countries whose history, like that of Palestine, seems out of proportion to their present circumstances. It is a pity, by the way, that in so good a paper nature should be spoken of as having produced in the camel "a Frankenstein." Frankenstein in the story was not the monster, but the monster's creator.

It is by no means certain that the harm which the camel is capable of doing in Egyptian territory has even yet been exhausted. The writer of the report considers it possible that the prosperity in Egypt in which all Englishmen are rejoicing may seal the destruction of the remaining trees, and leave the country bare save of *Calotropis procera* and the plants which nourish a few sheep and donkeys, attended by herdsmen, fed by grain from the Nile Valley. "The camel," he says, "will then, having so to speak burnt its boats, be domesticated in the Nile Valley. And it is interesting to speculate as to how he will develop there. Already the massive Cairo camel is a type distinct from other camels, surpassing all in its cumbrous massive proportions."

The December number of the *Kew Bulletin* contains, besides the paper on the disappearance of desert plants in Egypt, interesting sections on the Taj Gardens, Agra; Indian gutta-percha; the Gold Coast botanical station; Ramie machine trials at New Orleans; Lord Bute's "Botanical Tables"; and miscellaneous notes. Reference was made to the "Botanical Tables" in the historical account of Kew, printed in the *Bulletin* in 1891, p. 291. Since that was written the authorities at the Royal Gardens have had an opportunity, through the gracious permission of the Queen, of examining the copy in the Royal Library at Windsor, which formerly belonged to Queen Charlotte, to whom the work was dedicated. On the fly-leaf of the first volume of the Windsor copy is the following note in pencil, written by the Rev. John Glover (appointed Royal Librarian by William IV.):—"Of this work only sixteen copies were printed for presents, at a cost, it is said, of more than £10,000. This copy belonged to Queen Charlotte, and was purchased at the sale of Her Majesty's Library for, I believe, £100." There seem, however, to have been only twelve copies. The general nature of the contents is indicated in the *Bulletin*. There are nine volumes, and the work contains 654 plates, all of them apparently drawn and engraved by John Miller, an excellent German artist—Johann Sebastian Mueller, who thus anglicised his name.

Ceylon is sending to the Chicago Exhibition a complete reproduction of a Buddhist temple and many interesting specimens of ancient Sinhalese art, including, according to the *Ceylon Observer*, "exquisitely carved pillars, massive doorways and dados, beautiful windows and frescoed panellings of courts." There will also be, among other things, a display of jewellery, lace, and pottery. It is hoped that these treasures will do something to further in America "the interests of the most modern product of Ceylon, tea."

At the recent meeting of the Congress of Americanists at Huelva, Mrs. Zelia Nuttall, of the Peabody Museum of American Archæology and Ethnology, Cambridge, Massachusetts, presented a preliminary note on the calendar system of the ancient Aztecs. Guided by a statement in a Hispano-Mexican MS. which she has recently discovered in the National Central Library of Florence, Mrs. Nuttall claims to have found the key to the Aztec calendar system. She exhibited tables showing that the Mexican cycle was 13,515 days, and that it comprised 52 ritual years (less five days at the end of the cycle), of 260 days each, or 51 lunar years of 265 days each, based on nine moons, or 37 solar years each of 365 days. At the end of the fifty-first lunar year 10 intercalary days placed the solar years in agreement with the lunar years in such a manner that the new cycle recommenced in the same solar and lunar positions as the 13,515 preceding days. Each period commenced with a day bearing one of the four names: *acatl, tecpatl, calli, tochtli*. The calendar system and tables, 14 metres long, designed to

illustrate this communication, were subsequently placed on exhibition in the Spanish section of the Historical Exhibition at Madrid. Her Majesty the Queen of Spain commanded that Mrs Zelia Nuttall should be presented to her, and expressed much interest in her work

No one expects to see the corncrake in Great Britain after the summer months. According to the *Llangollen Advertiser*, a specimen was caught last Thursday in the neighbourhood of Pentrefelin, Llangollen Several local naturalists have seen the bird, and agree that it is a corncrake.

A NEW luminous fungus has been forwarded to Europe from Tahiti. It is said to emit, at night, a light resembling that of the glowworm, which it retains for a period of twenty-four hours after having been gathered, and it is used, by the native women, in bouquets of flowers for personal adornment in the hair and dress It belongs to the section "dimidiati" of the genus *Pleurotus*, in which no luminous species has been hitherto known, although there are several in the genus, and has been named by M Hariot *Pleurotus lux* It is believed to grow on the trunks of trees.

A THEORETICAL investigation of the conditions under which Lippmann's coloured photographs are produced is given by M G Meslin in the *Ann de Chim et de Phys* for November He maintains that the colours produced are complex, and belong to the higher orders of Newton's scale This is illustrated by the change in colour observed when the thickness of the film increases. When moist air is blown upon it the film swells, and the bright colours give way to others consisting principally of red and green The impure nature of the spectrum ordinarily obtained would account for its "metallic" appearance Besides, there is a blue or greenish blue region which extends beyond the red end of the spectrum The composite nature of the colours reflected from the surface of the spectrum photograph may be shown by projecting a similar spectrum upon the film The colours will then appear very brilliant But if, for instance, the green is projected upon the red of the film, green is reflected all the same, although less distinctly than before The same thing happens in other parts of the spectrum On moving it from the violet towards the red, the violet, arriving at the green portion, is interrupted by a broad band. On further displacement this band, the breadth of which is about equal to the distance between the E and the b lines, moves through the green and yellow and reaches the red. At this moment the blue and violet regions show the greatest brightness. There is only one band observed throughout. This observation is in accordance with the thickness attributed to the layers, viz. between 200 and $350\mu\mu$. Hence the paths traversed by the light will range from $400\mu\mu$ to $700\mu\mu$, giving $\frac{\lambda}{2}$ for none of the colours, $\frac{3}{2}\cdot\frac{\lambda}{2}=600\mu\mu$ for the violet, $650\mu\mu$ for the blue, and $700\mu\mu$ for the green. It will be still greater, i.e. $\frac{3}{2}\frac{\lambda}{2}$ for the red, in the infra red region of the spectrum. There we shall have a black band in the red, while the blue is at its maximum, owing to the retardation being equal to two wave-lengths. Hence the blue region beyond the red corresponds to the infra red region of the incident spectrum, which in long exposures is able to produce a photographic effect.

DURING the year 1891 about 450 more persons were killed by wild beasts in India than during the preceding year. The number in 1890, however, was abnormally low, and the *Pioneer Mail* calculates that last year's figures were about 250 in excess of the mean. In one district of Bengal—Hazaribagh—no fewer than 205 deaths were due to a single brood of man-eating tigers. The yearly average of persons destroyed by wild beasts in our Eastern dependency is between 2500 and 3000. The mortality from snake-bite is on a much larger scale. Year by year it varies from something over 21,000 to something over 22,000.

AN excellent account of the Experiment Stations established in the United States in the interest of agriculture is given by Mr R Warington, F R S, in a paper issued by the National Association for the Promotion of Technical and Secondary Education A fully equipped Experiment Station, he says, is a large and costly piece of machinery, embracing many departments of work There is one in every State of the Union, and in some States there are more than one, the total number is fifty four These Stations are endowed by Congress, £3000 a year being paid to the Station or Stations of each State If the income derived from the State Legislatures, and from other sources, be included, the average income of each Station is nearly £4000 In nearly every instance the station is connected with the States Agricultural College, and the Station buildings are in its immediate vicinity The publications of the Stations are made in the form of periodical bulletins and annual reports, for the printing of these a special grant is made by the State, and they are distributed by the Federal Government post free The issues are very large 60,000 copies of each Station bulletin are printed in Ohio Any farmer in the State can at his request receive the bulletins regularly without payment Mr Warington expresses a hope that our own County Councils may be encouraged to try to do for agriculture in Great Britain what is so energetically done for it in America by the various States

A SERIES of investigations on soils is in progress at the Maryland Agricultural Experiment Station, in co-operation with the U.S. Department of Agriculture and the Johns Hopkins University So far the work has been on the physical structure of the soil and its relation to the circulation of soil water, and the physical effect of fertilizers on soils as related to crop production The surface tension of various solutions was first of all determined The solutions chosen included common salt, kainit, superphosphate of lime, soil extract, and ammonia The soil extract was made by shaking up a little soil with just sufficient water to cover it. The water was afterwards filtered off and used for the determination This operation reduced the surface-tension of water considerably, but the experiments do not appear sufficiently complete to indicate reasons for this Analyses of the soils are not given Ammonia and urine lowered the surface-tension of water considerably below that of the soil extract, and still more below that of pure water Common salt and kainit increase the surface tension of water, and no doubt this is the reason why the application of these substances to the soil tends to keep it moist, whereas the excessive use of nitrogenous manure has the reverse effect

THE Chamber of Commerce at Reims has published the statistics of the trade in champagne since 1844. In 1844 45 the value of the trade was 6,635,000 francs, and in the following year it exceeded seven millions. In 1868 69 it amounted to nearly sixteen millions, but fell to nine millions in 1870-71, and then rose in 1871-72 to twenty millions. The value in 1872 73 was twenty-two millions, and it oscillated between this sum and seventeen millions until 1889-90, when it became twenty-three millions. The figures were 25,776,000 in 1890-91, 24,243,996 in 1891-92. The number of bottles used in France rose from 2,225,000 in 1844-45 to 4,558,000 in 1891 92, while the number exported rose during the same period from 4,380,000 to 16,685,900. The year in which most bottles were sent abroad was 1890-91 (nearly twenty-two millions)

MESSRS. SWAN, SONNENSCHEIN AND CO have issued a translation, by Dr E. L. Mark, Professor of Anatomy in Harvard University, of the third edition of Dr Oscar Hertwig's

"Lehrbuch der Entwicklungsgeschichte des Menschen und der Wirbelthiere" The volume is entitled "Text-Book of the Embryology of Man and Mammals" The translator, in his preface, expresses his belief that the work "covers the field of vertebrate embryology in a more complete and satisfactory way than any book hitherto published in English"

THE latest instalment of the Proceedings of the Academy of Natural Sciences of Philadelphia contains a valuable paper, by Prof. E D Cope, on the Batrachia and Reptilia of North Western Texas The statements presented in the paper are based on collections made along the eastern border of the Staked Plain of Texas, between Big Spring (on the Texas Pacific R R.) on the south, and the Salt Fork of the Red River, near Clarendon (on the Denver and Fort Worth R R) on the north, a distance of about 250 miles The collections were made incidentally to geological and palæontological explorations conducted by a party of the Geological Survey of Texas, which was under the direction of Mr William F Cummins While attached to this party Prof Cope picked up such specimens as came in his way, and a good many others were obtained by Mr Cummins and by Mr William L Black of the party The total number of species enumerated is thirty-three The paper may be regarded as supplementary to one published as Bulletin 17 of the U S National Museum in 1880, on the Zoological position of Texas

THE following are the lecture arrangements at the Royal Institution before Easter —Sir Robert Stawell Ball, six lectures (adapted to a juvenile auditory) on astronomy, Prof Victor Horsley, ten lectures on the brain, the Rev Canon Ainger, three lectures on Tennyson, Prof. Patrick Geddes, four lectures on the factors of organic evolution, the Rev Augustus Jessopp, three lectures on the great revival—a study in mediæval history, Prof C Hubert H Parry, four lectures on expression and design in music (with musical illustrations), the Right Hon Lord Rayleigh, six lectures on sound and vibrations. The Friday evening meetings will begin on January 20, when a discourse will be given by Prof Dewar on liquid atmospheric air, succeeding discourses will probably be given by Mr Francis Galton, Mr Alexander Siemens, Prof Charles Stewart, Prof A. H Church, Mr Edward Hopkinson, Mr. George Simonds, Sir Herbert Maxwell, Bart, the Right Hon Lord Rayleigh, and other gentlemen

THE micro organism which has been shown to be the exciting cause of tetanus or lockjaw is just now especially attracting the attention of bacteriological investigators. Kitasato, who it will be remembered was the first who successfully isolated the bacillus of tetanus, has been continuing his researches on the protective inoculation of animals against this malady. In the current number of the *Zeitschrift fur Hygiene* appears an account of some extremely interesting results which he has obtained with mice and guinea-pigs In his experiments Kitasato introduced subcutaneously into these animals small splinters of wood which had been previously soaked in bouillon-cultures of tetanus, so prepared that only the spores were present He wished in this way to imitate as nearly as possible the actual manner in which tetanus is communicated, and which in consequence of the sensitiveness of the bacillar form to heat and light and the extremely refractory nature of the spores, is almost invariably due to the accidental introduction of the latter This theory is also supported by the fact that between the infliction of the wound and the development of symptoms of tetanus there is invariably a distinct lapse of time, during which the spores grow into bacilli and elaborate their toxic products within the system of the animal affected, after which the typical appearances of tetanus arise. The protective material used in these investigations was the serum of a horse artificially rendered immune against tetanus, and in every case out of those mice which had received a small wood-splinter two were put aside and not subsequently inoculated with the protective serum Kitasato found, as he had expected, that a definite period of time elapsed between the introduction of the splinter and the development of tetanus symptoms, but with hardly an exception, all those mice subsequently treated with the serum recovered, whilst those which had received no protective treatment died exhibiting the typical characteristics of tetanus Moreover, it was found that the earlier the application of the serum took place after the infection and quite irrespective of the appearance of any signs of tetanus, the more successful was the result and the smaller the dose of serum necessary, whilst when the wood splinters and the serum were introduced together no symptoms whatever of tetanus declared themselves The same successful results were obtained in the case of guinea-pigs In connection with the excessively hardy nature of the spore-form of tetanus, Hervieјean (*Ann de la Soc méd chir de Liége*, 1891) has found that even after eleven years such spores still retain their power for mischief A small fragment of wood was extracted from the ankle of a child who had died of tetanus, and after being kept for nearly eleven years part of it was introduced under the skin of a rabbit, which afterwards died of tetanus The infection was further confirmed by the discovery of tetanus bacilli in the pus of the wound

THE chloraurates and bromaurates of cæsium and rubidium have been prepared by Messrs Wells and Wheeler, and are described in the current number of the *Zeitschrift fur Anorganische Chemie* They are all four beautifully crystalline substances The crystals, which have been measured by Mr Penfield, belong to the monoclinic system, and form an isomorphous series of identical habitus These salts are so comparatively insoluble in water that they are obtained in the form of crystalline precipitates when concentrated solutions of chlorides or bromides of cæsium or rubidium are mixed with strong solutions of chloride or bromide of gold They are, however, sufficiently soluble to admit of recrystallization from water The crystals of cæsium chloraurate, $CsAuCl_4$, exhibit an orange-yellow colour, those of the corresponding rubidium salt, $RbAuCl_4$, possess a more deeply orange tint, while the two bromides, $CsAuBr_4$ and $RbAuBr_4$, are jet-black but yield a dark red powder upon pulverization The cæsium compounds are much less soluble than the rubidium ones, so that the crystals are usually much smaller The more soluble rubidium salts readily form very large crystals; the chloride in particular yields crystals whose size appears only to be limited by that of the crystallizing vessel and the depth of the solution The crystals, however, whether large or small, all partake of the same character; they are elongated prisms terminated by the basal plane, orthodome, clinodome, and small pyramidal planes. The faces are usually extremely brilliant, but those of the bromides are often singularly hollow or cavernous In addition to this well defined series, another chloraurate of cæsium has been obtained containing water of crystallization This salt, $2CsAuCl_4.H_2O$, is formed when a large excess of gold chloride is present compared with the amount of cæsium chloride. It separates in the form of light orange-coloured tabular crystals belonging to the rhombic system, which exhibit the peculiar property of undergoing an internal change accompanied by elimination of the water of crystallization, within a few minutes of their removal from the mother liquor The change is probably due to the passage of this hydrated salt into the relatively more stable anhydrous chloraurate described above. It betrays itself in a most interesting manner under the microscope, in polarised light. When a crystal plate is removed from the mother liquor,

rapidly dried by means of blotting-paper and placed under the microscope, the Nicols being crossed, it simply produces the usual effect of causing the field to become coloured with some homogeneous tint But after the expiration of three or four minutes the molecular change begins to be rendered apparent at the circumference of the field by a rapid augmentation of the polarizing effect, in another moment it commences to dart across the field in all directions, the brilliantly coloured rays being feathered with offshoots, reminding one of the rays of crystallizing ammonium chloride This beautiful effect continues until, in less than ten minutes after the removal of the crystal from the mother liquor, the rearrangement of the molecules has become so general that light is no longer able to penetrate, and the crystal becomes completely opaque Messrs Wells and Wheeler have also attempted to prepare the analogous compounds containing iodine, but have not yet obtained them in a condition so pure or well crystallized as the salts described above

The additions to the Zoological Society's Gardens during the past week include a white fronted lemur (*Lemur albifrons* ♀) from Madagascar, presented by Mr M C Parker, a brown capuchin (*Cebus fatuellus* ♂) from Brazil, presented by Mr Earle Tudor Johnson, a large-eared fox (*Otocyon megalotis*) from Mashonoland, South Africa, presented by Mr B B Weil, two black-backed jackals (*Canis mesomelas*) from South Africa, presented by Capt. Ralph H Carr-Ellison, a common fox (*Canis vulpes* ♀) from Arabia, presented by Miss Morgan, a leadbeater's cockatoo (*Cacatua leadbeateri*) from Australia, presented by Lieut.-Colonel Warton, a Rhesus monkey (*Macacus rhesus*) from India, deposited

OUR ASTRONOMICAL COLUMN

Comet Holmes (November 6) —The following is the ephemeris for Comet Holmes for the ensuing week —

1892	R A. (app.) h m s.	Decl (app) ° ′	Log r	Log Δ
Dec. 15	0 49 34	+34 50 1		
16	50 15	45 8	0·4004	0 2813
17	50 57	41 6		
18	51 41	37 5		
19	52 27	33 6		
20	53 14	29 8	0 4027	0 2931
21	54 3	26 1		
22	0 54 53	+34 22 6		

Owing to the extremely bad weather, observations of this comet have not been numerous, but from all accounts not much change has taken place in the general appearance, except that the central nucleus seems to possess two small tails, which extend towards the ragged edge of the exterior portion

Comet Brooks (November 20, 1892) —Last week the only ephemeris of this comet at hand was one showing its position every fourth day, but Prof Kreutz has now communicated to *Astronomische Nachrichten*, No 3132, a daily ephemeris, from which the following is extracted —

1892.	R A. (app.) h m. s.	Decl (app). ° ′	Log r	Log Δ.	Br.
Dec. 15	13 50 10	+31 57·3			
16	54 6	33 17 2	0 0974	0 0001	3·67
17	13 58 19	34 41 2			
18	14 2 53	36 9 5	0·0946	9 9775	4 13
19	7 51	37 42·2			
20	13 17	39 19 3	0·0921	9·9550	4·63
21	19 13	41 0 8			
22	25 46	42 46·6	0·0898	9·9332	5·17

From the column showing the brightnesses it will be seen that a considerable increase in this comet is taking place. The comet will be easily found by the fact that it lies in the prolongation of a line joining β and γ Bootis (December 18) at a distance equal to that between those two stars.

The New Brooks' Comet —The following positions of this comet are reported from Marseilles, by MM Esmiol and Fabry —

Date	Marseille Mean Time h m s	App R A. h m s	App P D ° ′ ″
Nov. 24	17 45 16	13 3 14 6	74 51 33
24	17 6 53	13 4 39 39	74 33 18 1
29	16 43 46	13 11 1 76	72 11 46 7
30	16 41 49	13 12 45 77	71 34 49·0

The comet presented the appearance of a nebulosity about 1′ in diameter, diffuse at the edges, and brighter towards the centre, but without a well defined nucleus Its brightness was about that of a star of eleventh magnitude.

Nova Aurigæ —Nova Aurigæ has again increased in magnitude, observations showing that visibly it is 8 5, while photographically it is three magnitudes fainter

Astronomy at Columbia College, U S A —The latest number of the bulletin issued by this college informs us that with the consent of the governing body of the New York Hospital and the college trustees, a new but small observatory is about to be erected on the site Bloomingdale The instrument, which is at present being constructed by Wanschaff, at Berlin, is a zenith telescope, and it is one of a pair which is going to be used for observations to obtain accurate determinations of the variations of terrestrial latitudes The other instrument, by order of the Italian government, is going to be mounted at the Royal Observatory of Capodimonte Both instruments will soon be, if not already, in working order, the observers in America are Prof Rees and Mr Jacoby, while M Higola will undertake the Italian observations

The library of this college has been recently very much increased by the purchase of the fine library of astronomical and physical works belonging to Mr Struve, former director of the Pulkowa observatory This addition amounts to no less than 4361 bound and unbound books, together with 3056 pamphlets

Companion to the Observatory for 1893 —This annual *Companion* for the coming year is very similar to the one last published Mr Denning gives a list of the principal meteor showers deduced from recent observations, while ephemerides for the planets, together with their satellites, are also inserted Solar observers will find the ephemeris given on page 22 very useful, this table giving the position-angle of the sun's axis, and the heliographic latitudes and longitudes of the centre of his disc In addition to several other handy tables and ephemerides, the times of minima of variable stars not of the Algol type, variable stars of the Algol type, maxima and minima of variable stars, and finally a table of double stars are also included

GEOGRAPHICAL NOTES

Major Thys, who has recently returned from the Congo Free State, reports that the railway from Matadi to Stanley Pool is progressing rapidly. The works are practically completed for only 14 kilometers out of the 400, but this includes the most difficult region, including the greater part of the ascent to the plateau. In a few months it is hoped that 40 kilometers will be completed, and the malarial coast-belt can then be traversed rapidly, obviating a serious risk to the health of travellers to the Upper Congo.

We are pleased to find that the Manchester Geographical Society has published the concluding part of the seventh volume of its Journal although, as we had occasion to remark on the appearance of the previous part, it is greatly to be regretted that the people of Manchester do not take a greater interest in a Society which is one they have reason to be proud of It is, we are convinced, solely to this want of local appreciation that the Journal has to be issued so far behind its proper date as to impair the usefulness of its contents In the current number there is an interesting paper on Japan by Mr. W M Steinthal.

Mr. G A. Craig has, we understand, resigned the secretaryship of the Liverpool Geographical Society on account of ill-health.

The *Scottish Geographical Magazine* for this month contains a paper by Captain Lugard, entitled "Characteristics of African

Travel" The Society presented Capt. Lugard with its silver medal and an honorary diploma of Fellowship A similar award has been made to Mr Joseph Thomson in recognition of his services to Geography in Africa

Dr J Troll, an Austrian explorer, is at present engaged in a journey through Central Asia He reached Samarkand in the end of October Thence he proposes to pass through Russian and Chinese Turkestan and Mongolia, intending to return by Pekin and Shanghai In the course of his journey he hopes to visit the ruined city of Karakoram, the ancient capital of Jenghiz Khan.

A railway has recently been opened from Wiborg, in Finland, to the Imatra Falls, thus bringing the finest rapids in Europe within six hours of St. Petersburg Hitherto the falls have been reached by canal-steamer and coach, the journey occupying not much less than twelve hours

Mr. Joseph Thomson proposes to use the name "Livingstonia" to describe the whole British sphere of influence north of the Zambesi and west of Lake Nyasa It is little to the credit of British cartographers that the attempts hitherto made to associate Livingstone's name with the continent of which he was the greatest explorer have practically failed

THE DESTRUCTION OF IMMATURE FISH

Mr Ernest W L Holt contributes to the new number of the Marine Biological Association's Journal another very interesting paper on the results of his North Sea Investigations He has much to say as to the destruction of immature fish in the North Sea, and makes the following observations on proposed remedial measures —

It will be admitted that the continued destruction of large numbers of valuable fish before they have had a chance of reproducing their species can only result in increased deterioration of the industry, and that some measures must be taken to put a stop to it unless we are prepared, and able, by artificial propagation to restock the sea as fast as we deplete it Briefly the various proposals that have been put forward fall under three headings, viz. closure of grounds frequented by small fish, restriction of sale of undersized fish, and enlargement or alteration of mesh. We have seen that some of the smack-owners have adopted the eminently practical method of forbidding their boats to fish where they are likely to catch much small stuff; but the buyers, though as loud as any in their outcry, do not appear inclined to avail themselves of their undoubted power to check the evil The proposals for legislative action have been so much discussed of late that I need only advert to such as affect the North Sea district

It is a matter of common knowledge that the bulk of the destruction by deep-sea trawlers takes place on the eastern grounds, to which I have alluded elsewhere, and since these lie wholly or in part outside the three-mile limit, it has been proposed that they shall be closed to trawling by international agreement Whether such agreement could ever be arrived at is questionable and if it were, it is not likely that the ensuing legislation could be easily enforced The great extent of the grounds would involve an enormous and costly Marine Police force, of mixed nationality, and even were such a body much more efficient than one has any reason to expect, there might be considerable difficulty in adequately watching grounds which extend in some cases over fifty miles from shore Indeed, on our own coasts and elsewhere the success with which legislation limited to the territorial area has hitherto been enforced is hardly such as to encourage us to extend the principle to the open sea.

The various standards of size which have been advocated, in proposals for prohibiting the sale or possession of undersized fish, differ according as the subject has been treated with regard to the marketable qualities of the fish, or to its powers of reproduction; and it may be assumed, I suppose, without argument that the latter is the more rational method of treatment Still it may be as well to recapitulate the sizes proposed at the Fishery Conference at Fishmongers' Hall last February, since they may be taken to represent the most recent trade opinion on the subject.

They are for turbot and brill twelve inches, for soles and lemon sole (*Pleuronectes microcephalus*) ten inches, and for plaice eleven inches. How far they fall short of the biological limits, at least for the North Sea district, can be judged by comparing them with the table of sizes on p. 384 of the Journal; and, indeed, I may remark that the prohibition of the sale of turbot and brill under twelve inches in length is rather a work of supererogation, since the number of smaller fish of these species that come to market, at all events at Grimsby, is utterly insignificant

The benefit to be expected from any measure of prohibition depends of course on the vitality of the fish, and it is very generally asserted that the bulk of the small fish trawled on these eastern grounds would not survive if returned. My own experience leads me to believe that this view is correct[1] so long as the present system of long hauls is maintained Hence we must seek for such a limit as will render the grounds most frequented by these small fish unprofitable to the fishermen (since any less limit would only involve an infinitely greater waste than takes place at present), and in doing so it is necessary to glance at the general conditions of this fishery

Exclusive of less important forms, the species chiefly met with are plaice, turbot, and soles The plaice, on most grounds, do not exceed a length of fifteen inches, and are mostly less than thirteen inches in length The turbot are fairly abundant, but, as I have already shown, almost all immature, soles are scarce It is only the certainty of being able to fill up with small plaice that induces the fishermen to cross to the eastern side, since the soles and turbot would not nearly pay his expenses by themselves. Now I am confident that if the Conference limit of eleven inches for plaice were enforced, there would still be enough saleable fish left to make the grounds worth visiting, whereas if it were raised to fifteen or even fourteen inches the grounds would assuredly be left alone, and although such would be below the biological limit, I believe the practical closing to our huge fleets of such a magnificent nursery for young plaice would be in itself a sufficient protection for the species. Certain rough patches of ground, practically surrounded by areas yielding only small fish, abound with only large fish, these would still be accessible to fishermen, whereas in any scheme of geographical restriction it would hardly be possible to exempt them. Moreover the restriction of size would probably do away with the destruction of small plaice by shrimp or sole-trawls, since the fish are not injured by being caught in these nets, and if unsaleable[2] would probably be returned

For turbot, brill, and sole I would advocate the adoption of the biological standards They are all rather hardy forms, and it appears that immature brill and such immature turbot as are found on our own coasts are chiefly caught on certain banks where the intricate nature of the ground renders short hauls a necessity, so that they could be returned to the sea in good condition, as indeed the smaller of them usually are at present by many fishermen With regard to soles, I do not think that many undersized fish are caught by deep-sea trawlers,[3] and the substitution of a size limit for the present prohibition of the use of a fish-trawl in the Humber would do away with the anomaly of a law which is not enforced. There is a strong feeling amongst inshore fishermen that the bye-law alluded to is unequal in its operation, since it offers no check to the destruction of small fish on off-shore grounds, only accessible to large boats. Hence a regulation as to the size of fish landed is perhaps preferable to one based solely on territorial conditions somewhat imperfectly understood

An objection which I have heard urged against any scheme for keeping our trawlers off the eastern grounds is that the summer sole trade in the North Sea would thereby be left entirely in the hands of foreigners. I think that this is, perhaps, rather overstating the case, but anyhow I cannot see that it furnishes any excuse for the present enormous destruction of small plaice and turbot, whilst it is at least possible that the abstention of our own fleet from these grounds in the summer would result in a corresponding increase in the number of soles in the localities where that species congregates in the winter months. I have no knowledge of the migrations of soles, but the Great Silver Pit is equidistant from the Humber and the nearest eastern ground, and as it is the nearest point at which similar physical conditions can be attained, it does not seem improbable that the winter supply of soles in the Pit is in part recruited from the east side of the North Sea.

[1] Owing to the great mass of fish caught in a single haul, I consider it quite possible to hold this view without throwing any doubt on the value of the results obtained by my friend Dr Fulton in his experiments on the vitality of trawled fish (Report S F B, 1891).

[2] The possession, as well as the sale, should be prohibited, to guard against the possible danger of small fish being utilised as manure when the fisherman is also a farmer in a small way.

[3] The small soles caught on the Dogger and on the Dowsing are really solenettes (*Solea minuta*).

Another objection is that boats of British nationality are not the only ones engaged in the small fish trade, and it is true that during the summer months a number of German, Dutch, and Danish boats are occupied in catching small plaice. But they are all of small tonnage, some of them only open boats; and I understand that from the manner in which the trawl is handled by German and Danish boats no injury is done to the unmarketable fish, whilst the saleable part of the catch appears to be exported chiefly to London. Hence the proposed measures of prohibition would give no advantage to these nations. The German steam trawlers, according to my information, do not molest the small plaice at all. Of the proceedings of the Dutch bombs I have little knowledge, but from the small size of their gear, their share in the destruction cannot be a very large one. Foreign caught fish, except Norwegian salmon and mackerel and Dutch soles, including only a small percentage of undersized fish, rarely come to the Grimsby market, but on two occasions large consignments of small plaice, comprising, as I compute, some 31,000 fish, were sent from Denmark, and recently a consignment of turbot has arrived from Norway. These last fish were about 300 in number, all undersized, viz. from 9½ to 17 inches, whilst 4 were only from 8 to 9 inches. This is the only instance which has come under my notice of any considerable number of turbot less than 12 inches being present in the market, and, as we have seen, our own fishermen were not concerned in it.

The last and perhaps the most important objection arises from the difficulty in allowing for that variation in the size of fish of the same species on different parts of our own coast to which Mr. Calderwood alluded in the last number of the Journal, p. 208. The impossibility of utilizing a uniform size limit for all districts is sufficiently exemplified by the limit of 11 inches for the plaice proposed by the Conference of last February, which was the result of a compromise between the trade representatives of the North Sea and south and west coast districts. While perhaps unnecessarily high for the Plymouth district, we have seen that it is altogether too small for the North Sea. The difficulty of having different limits, of local application, will only be felt at such a central port or market as London, to which fish are brought, whether by rail or sea, from all districts, but with proper organization the obstacle does not seem insuperable. It is conceivable that the law might be evaded by running cutters from boats fishing in one district to the parts of another, where the limit was lower, but it is little likely that the firms which are in a position to undertake them, would lend themselves to such operations. There is not the slightest reason to apprehend a general conspiracy of evasion amongst the fishermen, and the boats which respected the law would form a more efficient police than all the cruisers in the navy, so far as one may judge by the conditions on the Scotch coast, where convictions of trawlers for infringement of the territorial restriction are frequently secured by the evidence of local line fishermen.

I must leave to others, who are acquainted with the local conditions, to decide whether the imposition of a size limit is desirable in other districts, but for the North Sea I have not the slightest hesitation in recommending this method of legislation, in the terms I have proposed above, as cheaper and likely to be infinitely more efficacious than any other that can be devised in maintaining the supply of the more important kinds of flat fish. I need hardly observe that its application to the halibut, which is chiefly a line fish, could not fail to be beneficial to that species, since there is no question but that fish caught on the hook will usually survive if returned;[1] but I do not think that the limit need be as high as the biological one, owing to the difference in the conditions of the trawl and line fisheries.

I am not prepared to enter at present into the question of mesh legislation, beyond pointing out that it appears to be the only method by which the destruction of immature round-fish, notably haddock and whiting, can be checked, since these species are fatally injured by being caught in the trawl, and would not survive if returned. Any great enlargement of the mesh does not appear advisable, since it would afford an opportunity of escape to the mature sole, of which that active species would be extremely likely to avail itself. The remedy seems to lie rather in an alteration of the arrangement of the meshes in the cod-ends, so as to prevent them from closing. On this subject I have been making investigations, but they are not yet sufficiently complete to yield reliable deductions. It is sufficiently evident, as has often been pointed out, that the great breadth of some of the flat-fish render it impossible to deal with the whole question by restrictions of mesh alone.

The last matter with which I have to deal is the destruction of very small fish by shove-net and shrimp "seines." If it were only possible to induce the men to cull out the small fish in the water they would do no harm at all, and practically I suppose that, as matters are, they do not greatly injure any species of known value except the plaice, although the small number of sole, turbot, and brill destroyed may represent, from the relative scarcity of these species, a more considerable injury than one would suppose. When fishing by day the shove-net men usually return the fish to the sea, but by night this is impossible, and the seine men do not seem to make any effort in that direction either by day or night.

It is a difficult question to deal with, since the shrimp appears to be almost a necessity to some people; at the same time the small plaice which are destroyed must represent an infinitely greater value than the shrimps. If hatcheries were established, and young turbot, brill, sole, and plaice were enlarged after they had been reared through the delicate larval and metamorphosing stages, it is reasonable to suppose that they would be conveyed or would find their way to the sandy margins, which seem best adapted to the succeeding stages of their life-history, only to fall into the net of the shrimper.

I should say that to prohibit the use of any sort of shore shrimp nets during night-time would be a beneficial measure, but there is perhaps sufficient reason for abolishing the industry altogether. Those engaged in it might be sufficiently compensated at a moderate expenditure, if indeed it be not contrary to public policy to admit the existence of a vested interest in an occupation which is essentially injurious to industries affecting a much greater section of the community.

[1] Except fish with air-bladders, caught at considerable depths.

THE NEW TELEPHOTOGRAPHIC LENS

IN a small pamphlet of thirty pages, written and published by Mr. T. R. Dallmeyer, the author brings together the various notices bearing on the subject of his new telephotographic lens that have appeared during the last twelve months. He also gives an account of the "simple" and "compound" telephotographic lens, with general instructions for their use, including tables of their properties, and a table showing the diameters of circles of illumination necessary to cover the various sized plates used at the present day.

The telephotographic lens is, we may say, the latest advance made in the science of optics as applied to photography. By it we are now able to obtain large pictures of animate things situated at long distances with short exposure. In this invention Mr. Dallmeyer has produced a useful, and what may prove a valuable, instrument, and he has opened up quite a new horizon which will not suffer from lack of workers.

Hitherto the principle involved in the apparatus for the production of large images consisted first in obtaining the primary image, and second in subjecting this image to the process of enlargement. To obtain the former a concave mirror, or more generally double convex lens, has been employed, while the subsequent magnification has been produced by placing a secondary magnifier or second positive lens behind the plane of the primary image.

This method, except in the case of astronomical work, has not been, we may say, popularly used, for the cumbrousness of the apparatus required, and the length of time necessary for exposure have quite prohibited its use for anything but inanimate subjects.

It is well known that the focal length of a lens is measured for practical purposes from the principal plane passing through one of the nodal points nearest the principal focal plane to that plane. In most lens-constructions this nodal point lies within the lens-mount. Now it will be seen that if this nodal point could be thrown in front of the lens, that is, on that side away from the focus, the focal length, if measured from the lens, would be shorter. This is exactly what Mr. Dallmeyer has done. In the simple telephotographic lens the anterior element, which is of large aperture and short focus, is a positive lens, while the posterior is negative, and of a fractional part of the focal length of the former lens. A diagram showing the lenses in position and the path of a ray of light remind one at first sight of the principle of the Galilean telescope, with this difference, that the rays emerging are not *divergent*, but *convergent*. In the construction

under consideration the size of the image thrown on the screen can be varied at will by simply altering the distance between the elements, but the further the lens is from the focussing screen, the more will be the time of exposure

With such a lens as this Mr Dallmeyer has taken many excellent pictures, but perhaps the best idea of its properties will be gathered from the facts obtained by photographing—by means of two cameras, one supplied with a "long focus landscape lens," and the other with the "new telephotographic lens"—the flame of an oil lamp placed at a distance of 20 feet With *equal* extensions of the camera the image of the flame given by the new lens was five times greater than that by the other

In the *compound* lens the anterior element before referred to is here replaced by a complete portrait lens, while a negative symmetrical combination takes the place of the posterior element This lens may be said to be more perfect than the *simple* lens, Mr Dallmeyer having been able to introduce considerable improvement in the construction

Some excellent work done with this lens has been exhibited by Messrs F Mackenzie and Annan at the Camera Club The pictures represented a building at a distance of 500 yards The first, taken with an ordinary rapid rectilinear lens with an extension of 14 inches, gave the house as ⅜ of an inch long The second—with the compound tele photo lens, extension 9 inches from the back lens—gave 2½ inches as the size of the house, while the third, with 30 inches' extension, gave the house as 6¼ inches Although these numbers can give one a very good idea of what this new lens can accomplish, yet the direct copies from photographs inserted in the pamphlet under consideration convey a more vivid impression

There is no doubt that this lens will find some very valuable applications, that of astronomical photography not being the least of them, for every one knows the great advantage a *short* telescope has over a long one if the degree of magnification in both are equal W

ARBORESCENT FROST PATTERNS

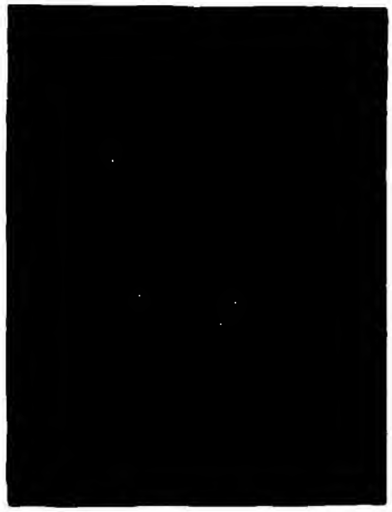
WE have received the following letters with regard to arborescent frost patterns, to which Prof Meldola called attention in last week's NATURE —

I AM very glad that Prof Meldola has called attention to the curved figures of frozen mud (of which the specimens on December 4 were unusually fine), because I hope that some one will explain why the sexangular crystallization which is universal in snow, and general in water, is exchanged both on windows and on muddy pavements for curves Probably I ought to know all about it, but I cannot remember seeing an explanation, and shall be obliged by reference to one, which will probably be of interest to others besides G J SYMONS

62, Camden-square, London, N W

THE interesting "fronds" of muddy ice observed by Prof. Meldola (p 126) are not very uncommon on the pavements in these "Northern Heights" I saw them on the date which he named, and have more than once studied them I then noticed that the "interstitial" pavement seemed partly cleared of mud, as if the water had drawn this towards the groups of crystals The mode of formation recalled to my mind certain phenomena in crystal building within rocks, and I suspect the mud has its influence. Indeed, it seems to me very probable that all these "dendritic" growths of crystals are the results of "impeded" or "constrained" crystallization, to some of which I have called attention in noticing a structure in the Charnwood syenite (*Quart Jour Geol Soc*, 1891, p 101) On this point Prof. Sollas makes some important remarks in his well-known paper on the Wicklow granites. T G BONNEY

THE beautiful curved forms assumed by the ice on the paving flags last Sunday were very noticeable in this neighbourhood and Hampstead as well as in other parts of London What I observed were not quite like those described and figured by Prof. Meldola, but resembled rather the scrolls and volutes which are frequently used in decorative art The finest piece that I saw was in this square, where several of these scrolls radiated from a central point, and spread over several feet of the pavement. A friend, Mr. E. Swain, observed that where one of these scrolls came upon a puddle of clear water the crystals were continued in a straight line Such forms are not at all unusual in the freezing of muddy water, and at the present moment the puddles in the road opposite my house are filled with rectilinear crystals of ice, which assume a curved form in the mud at their margins. The peculiarity on Sunday was their large size and beauty Something analogous takes place when gold or silver is reduced from solutions of its salts by more electro positive metals. Under certain circumstances



the metal will present itself in the form of curved crystals, if the term be allowable A pretty spray of gold of this character is figured in the report of my lecture "On the crystallization of silver, gold and other metals," in the proceedings of the Royal Institution, vi, 428 If a piece of cuprous oxide be immersed in a solution of nitrate of silver, there shoot from its surface thin threads of silver, which, after proceeding straight forward for a while, suddenly turn at an angle of 120° or 60°, and make perhaps many other deviations but sometimes these threads, instead of being straight, are curved, and in that case the threads that branch from them are curved likewise A magnified drawing of such a formation is given herewith These strange departures from the usual rectilinear course of crystal formation are very curious, and deserve more study than has hitherto been given them J H GLADSTONE.

17, Pembridge-square, December 10

PROF MELDOLA's letter (p 125) has been interesting to me, as I noted a striking and similar phenomenon here on Thursday, December 8, in the forenoon The trottoirs of several streets (east, west, north and south) were covered all over with beautiful patterns, somewhat different from Prof Meldola's illustration, there being innumerable dark, broad, sharply contoured leaf-like patches, distant several inches from each other, and connected by finely curved and branched tendril-like stalks. Foggy, with a faint north breeze I should presume the "leaves" were due to sparse drops of sleet fallen during the night.

Freiburg, Badenia, December 10 D WETTERHAN.

THE graceful arborescent frost patterns described by Prof Meldola in last week's NATURE were very conspicuous on the foot-bridge by the side of Charing Cross railway bridge, on the same morning, this being a situation still more exposed to the wind which he mentions as the probable cause

December 12. J T. RICHARDS.

I OBSERVED the same phenomenon as Prof Meldola describes in NATURE of December 8, on the same date, December 4, on pavements in Cheltenham, about 10 45 a.m ; after mid-day they had gone. I saw the patterns on pavements running north and south, as well as east and west. They were most exquisite; some like the illustration, others much more minute, but always in a connected design over the whole flag They had all the appearance of fossil vegetation. I never saw anything of the kind before J J ARMITAGE.

December 13.

MR. A. W. BENNETT and Mr. E. L. Garbett have also sent communications corroborating the phenomenon observed by Prof Meldola. The former attributes it to "defoliation of the stones as the result of weathering or wear"

THE MAKING OF RIFLES

AT a recent meeting of the Institution of Civil Engineers, Mr John Rigby, superintendent, Enfield Factory, read an interesting paper on the manufacture of small arms We reproduce from the abstract printed for the Institution Mr Rigby's lucid account of the various processes of manufacture of the components of the Lee Metford Mark I magazine rifle, of 0·303 inch bore, the weapon adopted for the British Army—an account which he prefaced with a general description of the Enfield Factory

The most important part of a rifle was the barrel, which had always engaged the special attention of gun-makers Up to the time of the Crimean War, it was, for the bulk of British troops, a comparatively rude tube of iron, lap-welded under rolls and tapering externally, with a cylindrical bore of about ¾ inch diameter The barrel of the present day was a steel tube of accurate workmanship, only $\frac{3}{10}$ inch bore, almost perfectly true and straight, rifled to $\frac{5}{1000}$ inch, and so closely inspected that the existence of the most minute grey or seam in the bore, requiring a highly-practised eye to detect it, was sufficient to condemn it The material used was produced either by the Siemens Martin or the crucible process of manufacture, and was supplied to Enfield as a solid round bar 1⅜ inch diameter and 15½ inches long After severe testing, this bar was passed through a rolling mill to draw it to its full length it was then taken to the forge, the swell at the breech-end was stamped to the required shape by a steam-hammer, and afterwards straightened cold The next step was to submit the bar, without annealing, to the turning and drilling-machines The latter were horizontal, the drills operating from each end. In the process of drilling, the barrel revolved at nearly 1,000 revolutions a minute against half round bits held flat down, a capillary tube, of brass, supplying a soap-and-oil emulsion, at a pressure of 80 lb to the square inch, to wash out the swarth and cool the cutting edge The drills advancing from each end continued boring until a small disk about $\frac{1}{10}$ inch diameter broke out, and the two holes met The tendency *of the drills to follow the line of axis of a revolving bar was* one of those curious occurrences in practical mechanics which might be accounted for after observation, but which no one would predict Occasionally, through some defect in the steel, a drill wandered from the axial line, in this case the barrel was taken from the machine and reset sufficiently to bring the hole true again To test its truth, a ray of light was made to illuminate the flat bottom of the hole while the barrel slowly revolved It was very rarely that a barrel was rendered waste from bad drilling Rough-boring followed with a three edged bit, the blade being about 4 inches long The rough external turning was effected in self acting lathes, which gave the required curved taper. Three or four cutters acted simultaneously, each producing a long cutting that attested the quality of the metal of the barrel The operation of barrel-setting followed Previous to rough turning, the barrels were fairly straight internally, but the removal of the metal caused slight inequalities which were tested by the eye of the barrel setter, and corrected by transverse blows. This constituted skilled labour of a peculiar character, and was performed by young men of good sight, who were specially trained for the purpose After middle life the eye generally lost some of the quality necessary for this work, and it was rare to find a man excel in it after that period. Many mechanical devices had been contrived to supersede the simple ray of light laid, as if it were a straight edge, along the surface of the bore, but the eye still remained the arbiter of straightness and could be relied on for very accurate results. The construction of the barrel was completed by the important operation of rifling In British small-arm factories the system was followed of planing out each groove separately with a hooked cutter, and had been brought almost to perfection In Continental and American factories the grooves were ploughed out by cutters, with several cutting or knife-edges set at an angle and following one another in the manner of a single-cut file or float. Similar machines had been tried at Enfield, but did not give as smooth a cut as the slower-moving, single-tooth machines. A few passes of a lead lap, fed with fine emery, removed any burr that might remain, and completed the polish; a cylindrical lap, spinning rapidly, was then passed through, and gave the final finish to the barrels. The limits of gauging were from 0·303 to 0·305 inch.

Next in importance to the barrel was the mechanism of the breech, for which the material preferred was crucible cast-steel of a mild character, but capable of being hardened in those parts exposed to the pressure of the bolt The body was forged in two operations under the steam-hammer, it was then drilled and subjected to a long series of operations, in the course of which the end was recessed to receive the screwed end of the barrel, and the corresponding thread in the recess was milled out in a specially-contrived machine, which insured that the thread should always start in the same place relative to the gauged part of the body, a point of great importance The bolt, also of crucible cast steel, was forged under the steam hammer A special machine, invented at Enfield, was used to finish the bolt after shaping After machining, the bolts, packed in wood charcoal in iron cases, were heated and hardened by immersion in oil The temper of the handle was then reduced in a lead bath The rest of the bolt was tempered straw colour The bolt-head was similarly hardened and tempered

The other components of a complete rifle were mostly shaped by mills built up to the proposed profile, or by copy-milling machines The process of drifting was used with good results at Enfield All such slots or perforations as had parallel sides, and were not cylindrical, were so finished. The common practice in drifting was to push the drift, but at Enfield much better work was accomplished by pulling It was found that used in this way drifts were very valuable for interchangeable work The sides were cut with successive teeth, each slightly larger than the preceding one, and the whole length of the drift was drawn through Emery wheels were also largely used at Enfield as a substitute for finish-milling and filing The wheels ran under hoods connected with a pneumatic exhaust that carried away the heated particles of steel and grit It was popularly supposed that a machine once adjusted to turn out a component of a certain size and shape was capable of reproducing such in large numbers, all absolutely identical This was so far from being the case that no die, no drill, and no milling-cutter actually made two consecutive articles the same size The wear of the cutters or dies proceeded slowly but surely, and it was only possible to produce in large numbers components of dimensions *varying between a superior and an inferior limit* In small-arm manufacture a variation of about one two thousandth of an inch was about the amount tolerated, but it varied according to the size of the piece A difference of diameter of one two thousandth of an inch in the sight axis-hole, and in the size of the pin or axis, would cause a serious misfit, whereas a similar difference in the measurement of the magazine, or of the recess in which it lay, would be quite immaterial The operations of gauging, proving the barrel, and sighting, were successively described, as also the manufacture of the stock, which was of the wood known as Italian walnut, though largely grown in other countries Among the smaller components, the screws were mentioned as being rapidly produced by the automatic screw-making machines of Pratt and Whitney.

The Component Store received the various finished parts, which numbered 1591, or, including accessories, 1863, and issued them to the foreman of the assembling shop Theoretically, the assemblers should have nothing to do but to fit and screw them together, but in practice small adjustments were found necessary The amount of correction was generally exceedingly small, and was done wherever possible with the aid of emery wheels The completed arms were submitted to inspection, and then issued in cases of twenty each to the Weedon Government Store or elsewhere

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—The General Board of Studies propose that, in view of the increased attention given to palæontology in the Geological Department, a Demonstrator in Palæozoology be appointed, whose stipend shall be paid out of the students' fees.

The Botanic Garden Syndicate report the completion of the fine range of plant-houses, which have for some years been in course of erection at a cost of some £6000. It is noteworthy that the expense has been kept within the estimate

The Senate has determined to raise the fee for the Doctor's degree (including M D. and Sc.D) from £20 to £25. It has rejected the proposal to increase the annual dues of undergraduates from 17s. to £2, and of graduates from 17s to £1, which was put forth in view of the financial needs of the University, by the Fees Syndicate The proposal to accept life-

compositions for the annual dues was also rejected Dr Allbutt Regius Professor of Physic, has been appointed an Elector to the Chair of Botany, in the place of the late Dr Hort

The discussion on the plans for the new Geological Museum (given at length in the *University Reporter* for December 13) was highly interesting, and appears on the whole to have been favourable to the scheme proposed, subject to relatively unimportant modifications Prof Newton objected that the arrangement of its contents should be zoological rather than stratigraphical, and the Registrary (Mr J W Clark) took exception to the plan of lighting, which would be better if it were from the top rather than the sides The geological staff were unanimous that the plan put forward was that which best met their needs It was agreed that the architectural effect of the museum would be very fine, and worthy of Sedgwick's memory

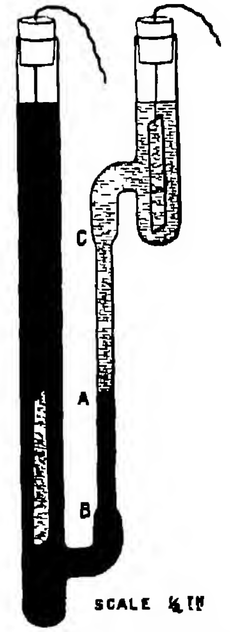
SOCIETIES AND ACADEMIES

LONDON

Royal Society, November 24.—"Ionic Velocities." By W C. Dampier Whetham, B A, Fellow of Trinity College, Cambridge Communicated by J J Thomson, F R S

From a series of determinations of the electrolytic conductivity of various salt solutions combined with Hittorf's values for the migration constants, Kohlrausch calculated the velocity of different ions under a potential gradient of one volt per centimetre Dr O Lodge actually observed the velocity of the hydrogen ion as it travelled along a tube filled with sodium chloride dissolved in jelly, decolourizing phenol-phthallein as it went He found 0029 cm per sec, and Kohlrausch gives 0030

The author has measured the specific ionic velocity of other ions by observing the motions of a junction between two salt



solutions of slightly different density and different colours, when a current was passed across it From the velocity of the boundary, that of the ion causing the change in colour can be deduced, The apparatus consisted of two vertical glass tubes about 2 cms. in diameter, joined by a third considerably narrower, which was bent parallel to the others for the greater part of its length The tube was filled with the solutions in such a manner that the boundary was formed in the vertical part of the junction tube.

When the solutions are of different specific resistances there will be a discontinuity of potential gradient at the boundary and a consequent electrification. The effect on the velocity of the boundary is, however, non-reversible, and, for small differences, can be eliminated by taking the mean of the velocities in opposite directions. The direct estimation of potential gradient is unsatisfactory, but by measuring the current (γ), the area of cross-section of the junction tube (A), the specific resistance of the solution (r), and the velocity of the boundary (v) we can find the specific ionic velocity v, for $v_i = \frac{vA}{\gamma r}$.

The first solutions used were those of copper and ammonium chlorides dissolved in aqueous ammonia, the former being blue, the latter colourless. The junction travelled with the current with a velocity of 1 57 cm per hour going upwards and of 1 60 cm per hour coming downwards The mean gives as the specific ionic vel of Cu in solutions of 1 gram equiv. per litre 000309 cm per sec. This agrees exactly with Kohlrausch's number for infinitely weak solutions of '00031 cm per sec Other measurements were made for chlorine and for the bichromate group (Cr_2O_7).

The method was extended to alcohol solutions The velocities of both ions of a salt were determined by using two pairs of solutions. Thus the velocity of chlorine was found by using a cobalt chloride-cobalt nitrate pair, the colours of which are blue and red respectively, and that of cobalt by a cobalt chloride-calcium chloride pair, these being blue and colourless The sum of these velocities was compared with that deduced by Kohlrausch's method from the conductivity of the solution The following are the results :—

SPECIFIC IONIC VELOCITIES

I —*Aqueous Solutions.*

Ion	Velocity observed	Velocity calculated
Copper	0 00026* 0 000309	0 00031
Chlorine	0 00057* 0 00059*	0 00053
Bichromate group (Cr_2O_7)	0 00048 0 00047 0 00046	0 000473

* Preliminary observations.

II —*Alcoholic Solutions.*

Salt	Vel of Anion observed	Vel of Kation observed	Sum of vels. observed	Sum of vels calculated
Cobalt Chloride	0 000026	0 000022	0 000048	0 000060
Cobalt Nitrate	0 000035	0 000044	0 000079	0 000079

December 8 —"On the Velocity of Crookes' Cathode Stream" By Lord Kelvin, P R S

In connection with his splendid discovery of the cathode stream (stream from the cathode in exhausted glass vessels subjected to electric force), Crookes found that when the whole of the stream, or a large part of the whole, is so directed as to fall on 2 or 3 sq. cm of the containing vessel, this part of the glass becomes rapidly heated up to many degrees, as much as 200° or 300° sometimes, above the temperature of the surroundings.

Let v be the velocity, in centimetres per second, of the cathode stream, and ρ the quantity of matter of all the molecules in 1 c c. of it Supposing what Crookes' experiments seem to prove to be not far from the truth, that their impact on the glass is like that of inelastic bodies, and that it spends all their translational energy in heating the glass The energy thus spent, per square centimetre of surface struck, per second of time, is $\frac{1}{2}\rho v^3$, of which the equivalent in gramme water centigrade thermal units is approximately $\frac{1}{2}\rho v^3/42{,}000{,}000$. The initial rate at which this will warm the glass, in degrees centigrade per second, is

$$\frac{\frac{1}{2}\rho v^3}{10^6 \times 42\ \sigma a} \quad \ldots \quad \ldots \quad (1),$$

where σ denotes the specific heat of the glass, and a the thickness of it at the place where the stream strikes it

The limiting temperature to which this will raise the glass is

$$\frac{1}{E} \times \frac{\frac{1}{2}\rho v^3}{42{,}000{,}000} \quad \ldots \quad \ldots \quad (2)$$

where E denotes the sum of the emissivities of the two surfaces of the glass in the actual circumstances.

It is probable that ρ differs considerably from the average density of the residual air in the enclosure. Let us take, however, for a conceivably possible example, $\rho = 10^{-8}$, which is what the mean density of the enclosed air would be if the vessel were exhausted to 8×10^{-6} of the ordinary atmospheric density.

To complete the example, take

$$v = 100,000 \text{ cm. per sec.}$$

(being about twice the average velocity of the molecules of ordinary air at ordinary temperature); and take

$$\sigma a = \tfrac{1}{4} \text{ cm},$$

as it might be for an ordinary glass vacuum bulb, and take

$$E = \tfrac{1}{8000},$$

which may not be very far from the truth

With these assumptions, we find, by (1) and (2) approximately, 1° per second for the initial rise, and 375° for the final temperature, which are not very unlike the results found in some of Crookes' experiments

The pressure of the cathode stream of the velocity and density which we have assumed by way of example is ρv^2, or 100 dynes per square centimetre, or about 100 milligrams heaviness per square centimetre, which is ample for Crookes' wonderful mechanical results.

The very moderate velocity of 1 kilom per second which we have assumed is much too small to show itself by the optical colour test. The fact that this test has been applied, and that no indication of velocity of the luminous molecules has been found, has, therefore, no validity as an objection against Crookes' doctrine of the cathode stream

Chemical Society, November 17.—Sir Henry Roscoe, Vice President, in the Chair —The Chairman congratulated the Fellows on the great improvement effected in the Society's rooms by the alterations carried out during the recess An address has been forwarded to the sister society in Berlin on the occasion of the celebration of its twenty-fifth anniversary A resolution was passed at a meeting of the Council expressing deep regret that, through the death of Dr Longstaff on September 23 last, the Society has lost its senior Fellow and one of its Founders. The following papers were read:—Fluosulphonic acid, by T E. Thorpe and W. Kirman This paper has been already reported in this volume, page 87.—Note on the interaction of iodine and potassium chlorate, by T E Thorpe and G H Perry The reaction which occurs when iodine and potassium chlorate are heated together is usually represented by the equation $3KClO_3 + I_2 = KClO_4 + KCl + KIO_3 + ICl + O_2$, the authors find, however, that the main reaction consists in a simple interchange of iodine and chlorine thus—$2KClO_3 + I_2 = 2KIO_3 + Cl_2$.—The magnetic rotation of sulphuric and nitric acids, and of their aqueous solutions, also of solutions of sodium sulphate and lithium nitrate, by W H Perkin, sen The author has previously shown that the molecular rotation of sulphuric acid is considerably influenced by the presence of water, the rotation rapidly falls for small dilutions, but diminishes as the amount of water is increased The results are now extended, in the cases of sulphuric acid and sodium sulphate there is no apparent connection between the values representing the rotation and the extent to which dissociation is supposed to occur down to solutions containing 9 per cent. of acid or 12 per cent. of sodium sulphate At a temperature of 90° the rotation is increased instead of diminished as indicated by the dissociation hypothesis. The results are not inconsistent with the assumption that the hydrate $(HO)_4SO$ is formed In the case of nitric acid, the curve connecting rotation and percentage of acid is a straight line down to solutions containing 33 per cent. of HNO_3, and then apparently bends down somewhat; the results are not in agreement with the exigencies of the dissociation hypothesis. A compound of the composition $(HO)_3NO$ may be produced. Lithium nitrate resembles nitric acid in its behaviour. The rotations of strong aqueous solutions of the haloid hydrides change very rapidly with small dilutions, but more slowly with larger dilutions, becoming finally nearly stationary; such behaviour is not in accord with the dissociation hypothesis.—Note on the refractive indices and magnetic rotations of sulphuric acid solutions, by S. U Pickering. Van der Willingen's results for the refractive indices of sulphuric acid solutions yield curves showing a well-marked "break" at 84·5 per cent. (H_2SO_4, H_2O), another "break" at 57 7 per cent. (H_2SO_4, $4H_2O$), and another at 24–30 per cent. The first two of these are also found on the magnetic rotation curves and all three of them agree with breaks found in the examination of other properties. The molecular volumes of solutions of the same strength as those used by Perkin when plotted out exhibit the same three breaks on the curve.—The hydrate theory of solutions Some compounds of the alkylamines with water, by S U Pickering The following table gives the compositions of a number of crystalline hydrates of fatty amines which the author has succeeded in isolating and analyzing —

$EtNH_2,5H_2O$	$EtNH_2,5·5H_2O$
$PrNH_2,5H_2O$	$Bu^{\alpha}NH_2,7H_2O$
$Et_2NH,5H_2O$	$Me_2NH,7H_2O$
$Pr_2NH,5H_2O$	$Pr^{\alpha}NH_2,8H_2O$
Me_2NH,H_2O	$PrNH_2,8H_2O$
$Et_3N,2H_2O$	$Et_2NH,8H_2O$
$Me_3N,3H_2O$	$Me_3N,11H_2O$

The freezing points of the hydrates ranged from + 5° to − 71°; indications of the existence of other hydrates were also obtained by "breaks" in the curves representing the freezing points of the solutions, and in every instance but one a hydrate of the composition thus indicated in the case of one amine was actually isolated in the crystalline condition in the case of some other amine In connection with this subject Prof Thorpe showed a very pretty experiment to illustrate the fact that whilst a mixture of triethylamine (15–50 per cent) is clear and transparent at ordinary temperatures, the solution becomes turbid on warming, owing to the amine being thrown out of solution, on applying pressure to the warm liquid, however, re-solution occurs.—The atomic weight of boron, by E Aston and W Ramsay The authors have investigated the atomic weight of boron, the atomic weight found from determinations of the water of crystallization of borax is 10 921 ± 0 01 The conversion of anhydrous sodium borate into sodium chloride by distilling it with hydrochloric acid and methyl alcohol and weighing the sodium chloride obtained gives an atomic weight of 10·966 for boron The authors consider that Abrahall's number (10 825) for this constant is too low, as the boron bromide employed by him might have been contaminated with the compound BBr_3,HBr.—Methoxyamido-1 3-dimethylbenzene and some of its derivatives, by W R Hodgkinson and L. Limpach An almost theoretical yield of 1 2 · 4-metaxylenol may be obtained by steam distilling a diazotized 5 per cent. solution of the corresponding xylidine sulphate The product solidifies in a mixture of solid carbonic anhydride and ether On nitration a theoretical yield of a mononitro-derivative ($NO_2 . OH = 1\ 2$) is obtained A number of other compounds are described.—An extra meeting of the Society will be held on Tuesday, December 13, at 8 p m, the anniversary of the death of Stas A paper by Prof J W Mallet, entitled "Jean Servais Stas, and the measurement of the relative masses of the atoms of the chemical elements" will be read and discussed

Physical Society, Nov. 25.—Prof S P Thompson, F R.S, Vice-President, in the chair.—The following communication was made: Experiments in electric and magnetic fields, constant and varying, by Messrs Rimington and Wythe Smith In the first set of experiments shown exhausted electrodeless tubes and bulbs were rotated rapidly in a constant electric field between two parallel charged discs. Double fan-shaped images were produced by the tubes, due to the displacement currents which pass to equalize the potentials at the ends of the tubes These fans were not symmetrical with respect to the lines of electric force, but were displaced in the direction of rotation In explanation of this phenomenon it was pointed out that as a tube rotated the potential difference between its ends increased until this difference was sufficient to break down the dielectric in the tube The discharges would therefore pass at the ends of the intervals during which the difference of potential was rising, and consequently the images would be displaced from the symmetrical position in the direction of rotation. The number of discharges produced during one revolution was found to depend on the strength of the electric field, but not on the speed of rotation, and that end of the tube which was approaching the negatively charged plate appeared brightest. These experiments were referred to as examples of the direct conversion of mechanical energy into light. Instead of rotating tubes in a constant electric field, the tubes were next kept stationary, and a varying electric field produced by connecting the plates with an influence machine allowed to spark, under these conditions the tubes and bulbs were seen to glow. Using large suspended plates charged by an induction coil, long tubes were caused to glow brightly even at considerable distances away from the plates. The glow could be apparently wiped out by passing the

hand along the tube. Another series of experiments were performed in varying magnetic fields. With a view to showing Hertzian phenomena to large audiences the authors tried Geissler tubes to replace the spark-gap in resonators, with great success. When large Leyden jar circuits were used the effects were very brilliant. Another form of resonator consisted of a bent wire terminating in two plates, between which an exhausted tube was placed. This tube became luminous when the resonator was placed in the vicinity of a fairly large Hertz oscillator. Other experiments similar to those shown before the society at Cambridge by Prof. J. J. Thomson, on discharges in exhausted bulbs were then made, the bulbs being placed with a coil of wire of four turns, forming the connection between the outer coatings of two small jars, whilst sparks passed between knobs connected with the inner coatings. The bulbs glowed brightly at each discharge, rings of light being seen near their inner surfaces. On putting a ring tube outside the coil this was also seen to glow. The most brilliant part of the glow always occurred in close proximity to the wire coil. A secondary coil, wound by the side of the above-mentioned primary, could be short-circuited at will; this had the effect of decreasing or extinguishing the luminosity in the bulb or tube. Bright sparks passed between the secondary terminals when held a short distance apart, but the shock experienced by touching the ends was not serious. The above arrangement, with the addition of two Geissler tubes placed in series between the outer coatings of the jars, was used to illustrate the fact that closing the secondary diminishes the impedance of the primary circuit of a transformer. Experiments on condensers made of tin foil on glass were shown. In one of them, parts of the coatings in the form of letters had been removed, and the spaces became luminous when the condenser was connected with an induction coil. In another experiment a glass plate was moved to and from a condenser, and a musical note could be heard whose pitch increased as the distance between the glass plates diminished. The note was said to be the octave of an open organ pipe, whose length was equal to the distance between the plates. Mr. Swinburne thought some of the effects shown were not Hertzian, but merely cases of ordinary mutual induction. He inquired whether the vacuum tubes would still glow if the Leyden jars were removed from the so-called resonating circuits. He was also of opinion that in the magnetic experiments the surfaces of the bulbs, and not the enclosed gases, took the charges. Mr. Watson asked if the authors had tried screening off the long waves by a wet cloth. If the effects still existed, this would prove that they were Hertzian. Mr. Blakesley wished to know if the images of the rotating tubes were at equal angular distances. Mr. Smith pointed out that these distances were not equal, but corresponded to equal changes of potential. Prof. Ayrton remarked that the only cases where the materials of the bulbs, tubes, &c., did not influence the results were those in which discharges were produced by varying magnetic fields. Mr. E. T. Carter thought an induction coil a more efficient machine for producing the glow in tubes than the alternator, &c., used by Mr. Tesla. Mr. Trotter asked if the authors had observed whether the glow produced by passing a discharge through a wire wound in a long pitch spiral round a tube formed an open or a closed circuit of light. Prof. S. P. Thompson said he first noticed that sparks passed between pieces of metal in the vicinity of an induction coil sparking into a condenser in 1876, when he was showing some experiments on telegraphic apparatus before the society, but unfortunately he did not pursue the subject. Long before Mr. Tesla's investigations Dr. Bottomley had shown that exhausted tubes could be caused to glow, but it was not until Tesla produced such phenomena on a large scale that people recognised how much light could be got in that way. Mr. Rimington, in replying to a question by Prof. Thompson, said the notes heard when the glass plate approached the condenser were of very high pitch. The explanation why in the experiments performed in varying magnetic fields, the bright parts of the luminous discharges were near the wire, appeared to be that the E.M.F. was greatest in these places. Although he had not tried the experiment, suggested by Mr. Swinburne, of taking off the Leyden jar, he felt sure that doing so would stop the glow.

Geological Society, November 23.—W. H. Hudleston, F.R.S., President, in the chair.—The following communications were read:—Outline of the geological features of Arabia Petræa and Palestine, by Prof. Edward Hull, F.R.S. The region may be considered as physically divisible into five sections, viz. (1) The mountainous part of the Sinaitic Peninsula; (2) the table-land of Badiet-el-Tîh and Central Palestine; (3) the Jordan-Arabah valley; (4) the table-land of Edom, Moab, and the volcanic district of Jaulân and Haurân; and (5) the maritime plain bordering the Mediterranean. The most ancient rocks (of Archæan age) are found in the southern portion of the region; they consist of gneissose and schistose masses penetrated by numerous intrusive igneous rocks. They are succeeded by the lower carboniferous beds of the Sinaitic peninsula and Moabite table-land, consisting of bluish limestone with fossils, which have their counterparts chiefly in the carboniferous limestone of Belgium, and of a purple and reddish sandstone (called by the author "the desert sandstone," to distinguish it from the Nubian sandstone of Cretaceous age), lying below the limestone. The Nubian sandstone, separated from the carboniferous by an enormous hiatus in the succession of the formations, is probably of Neocomian or Cenomanian age, and is succeeded by white and grey marls, and limestones with flint, with fossils of Turonian and Senonian ages. The Middle Eocene (Nummulitic limestone) beds appear to follow on those of Cretaceous age without a discordance, but there is a real hiatus, notwithstanding the apparent conformity, as shown by the complete change of fauna. In Philistia a calcareous sandstone in which no fossils have been observed is referred to the Upper Eocene; for the Miocene period was a continental one, when faulting and flexuring was taking place, and the main physical features were developed—*e.g.* the formation of the Jordan-Arabah depression is referable to this period. In Pliocene times a general depression of land took place to about 200–300 feet below the present sea-level, and littoral deposits were formed on the coasts and in the valleys. To this period belong the higher terraces of the Jordan-Arabah valley. The Pliocene deposits consist of shelly gravels. Later terraces were formed at the epoch of the glaciation of the Lebanon mountains, when the rainfall was excessive in Palestine and Arabia. The volcanoes of the Jaulân, Haurân, and Arabian desert are considered to have been in active operation during the Miocene, Pliocene, and Pluvial periods; but the date of their final extinction has not been satisfactorily determined. After the reading of this paper the president remarked on the interest of the geology of an area, which was that of the Bible. Many authors had recorded their observations on this district, one of the latest being the author of this paper. Some years ago Mr. Holland had read a paper before the Society, and he (the speaker) believed that that writer was actually the first to prove the existence of carboniferous fossils in the Sinaitic peninsula. He remarked that *Lepidodendron mosaicum*, described by Salter, was somewhere preserved in the Society's museum, so that the Society had long ago had evidence of carboniferous rocks. Mr. Bauerman's paper, which was a reconnaissance in a comparatively unknown district, created great interest; and when that paper was read doubt was expressed as to whether the fossils then exhibited were carboniferous or triassic. After the researches of Prof. Hull there was no doubt that carboniferous rocks do occur in the region. As regards the granitic rocks (extending far up the Nile valley, in the Sinaitic peninsula, and elsewhere), they were all of much the same character, and, according to Sir William Dawson, occurred at two horizons—the lower rocks being granitoid and gneissic, the upper more or less volcanic, but still pre-carboniferous. He asked the author whether the Poudingues de Jebel Haroûn of Lartet were or were not ancient volcanic rocks. The Nubian sandstone of older writers included many things, but the age of the various sandstones was now satisfactorily determined by the author. Some were carboniferous, others (in the speaker's opinion) cenomanian. The calcareous formations of Judæa were well known from the writings of Lartet, Fraas, and others; but the exact line of demarcation between the Nummulitic limestone and the true Cretaceous had never been determined. It was a curious fact, as stated by Von Zittel, that not one fossil was common to the two deposits, which were nevertheless quite conformable. Miocene beds appeared to be absent, for, as noted by Lartet and confirmed by the author, this was a period of movement, when the great valley and the great fault were initiated. He (the speaker) felt that there were many difficulties connected with the depression which had not yet been cleared up. Lartet, Hitchcock, and others had traced the general direction of the fault; but the author had determined its exact site at more than one point. The most interesting point in this connection was the question of the age of the 700-foot saddle separating the Akabah watershed from the Jordan-Arabah depression. This

THURSDAY, DECEMBER 22, 1892

MR C. DIXON ON BIRD-MIGRATION.

The Migration of Birds: an Attempt to reduce Avian Season-Flight to Law By Charles Dixon (London Chapman and Hall, 1892.)

AMONG prevalent fallacies there are few more mischievous than that which holds a man to be an authority on a subject because he has written a book about it If the subject be one concerning which the scientific hold divers opinions, or even hesitate to deliver an opinion at all, so much is to the good of such an author, for he will be able to pose all the more securely in the character of a *savant*—though after all that only signifies a "knowing one" If the author can boast of some two, three, or even half-a-dozen works already published, the fallacy becomes almost insuperable, notwithstanding that in zoological works of a popular nature, it is scarcely too hard to say that those who write the most know the least. Nevertheless it remains the duty of the conscientious reviewer to be instant in season with his protest against this general confounding of author with authority We have read several of Mr Charles Dixon's works, but hitherto we have been so fortunate that we have been able to keep *in petto* the judgment we have formed of them. It is not given, however, even to reviewers to struggle against fate, and it has been ordained that we should have to criticize his recent volume, the title of which may be read above To the first sentence of his preface—"There is no branch of Ornithology more popular than that which treats of the Migration of Birds"—we offer no strong objection, and rejoice that there is one spot of ground, be it never so small, that we may occupy in common, but (woe it is !) that here we must part company, for the very next sentence contains a statement which we would willingly let pass as a harmless exaggeration, were it not intensified by the words which follow—and "after that, the dark"!

Mr. Dixon's acquaintance with the subject he has selected is shown by the beginning of his second paragraph—"Notwithstanding the immense popularity and importance of Migration, strange as it may seem, no work has hitherto been devoted expressly to its discussion" He is therefore not aware of the essays of Schlegel and of Marcel de Serres, which (whatever we may now think of them) were in their time "crowned" by the scientific society that published them, and though he straightway proceeds to name the works of Professor Palmén and Herr Gatke, it is to complain of them that they "have only dwelt upon a portion of the subject." Far be it from us to say that Mr. Dixon has not read their works, but really there is nothing to show that his knowledge of them is more than may be picked up from the extracts which have been translated into English and published in this country, or that he has read them to any purpose—that of Herr Gätke especially, because, when further on (pp. 181-186) he comes to deal with it more particularly, he regards it as if it were a "mere record of captures or reputed captures of birds in Heligoland, speaking of it with contempt, and the original and rather peculiar views on migration of its author are passed over in silence, as though they were utterly unknown to him. Mr. Dixon states that he is "equally cognizant of the researches of Weissemann" (*sic*) and others, which, except that Dr Weismann, we think, would deny his having made any, we do not take upon ourselves to gainsay, though our older writers are utterly ignored, and we have a shrewd suspicion that the anonymous author of the "Discourse on the Emigration of British Birds," published at Salisbury more than one hundred years ago, was, from actual observation, more familiar with the main facts than Mr Dixon is—all flourishes about "avian fly-lines" and "season-flight" notwithstanding—and therefore would have been more competent than he "to bring our knowledge of Migration within the limits of order or to reduce it to Law"

Now this is exactly what in our opinion Mr Dixon has not done. What the "Law of Migration," of which we read here and on the title-page, may be it passes us to discover The phrase is full of sweetness, but its elucidation, if we may say so, fails in light So also is that about bringing our knowledge "within the limits of order," though that may be here taken to mean a dissertation within the limits of 300 pages or thereabouts containing something on the origin and descent of birds, a good deal about the precession of the equinoxes and the eccentricity of the earth's orbit, but still more about glacial epochs Concerning the "Law of Migration" it is pointless Let our author at once speak for himself in what seems to be a sort of summary of his faith, though it is long and not reserved to the end of his volume —

"We will now conclude by following in detail the migration of some single species, say from its Post Pliocene glacial initiation to the present day, in order clearly to demonstrate Why the habit [of migration] has been acquired, and How it is practised

"We will select the Spotted Flycatcher (*Muscicapa grisola*) for the purpose It is one of our best known summer migrants, and one whose present geographical distribution admirably illustrates the phenomenon of Migration When the Sub Polar regions of the northern hemisphere last enjoyed a warm, almost semi-tropical climate—one of the mild periods of the Glacial Epoch—the Spotted Flycatcher inhabited in one unbroken area the Arctic woodlands from the Atlantic to the Pacific. Probably it was a resident species becoming partially nocturnal during the Polar night, food was abundant, its conditions of life were easy, and it multiplied apace, and became a dominant, firmly established species during the thousands of years that it dwelt in this Sub-Polar habitat. So matters continued until the slow precession of the equinoxes, in conjunction with increasing eccentricity of the earth's orbit, began to have a marked influence on the climate, and gradually the fair forests and the verdant plains were devastated by the ever-increasing cold Age after age the Spotted Flycatcher was driven slowly south; summer after summer grew colder and shorter, the periods of Polar darkness more severe. At last matters became so serious that the birds began to leave their northern haunts in autumn, probably because their food became scarce as the various insects either retreated south or began to hibernate Further and further southward these annual journeys had to be taken, until the Flycatcher at last found its way during winter into Africa, Persia, Arabia, India, China, and even the Philippines and the Moluccas. Summer after summer the belt of breeding-ground became wider and wider, and vast numbers of individuals became separated from

the rest of the species by the lofty mountain ranges, the deserts, and other physical barriers, which would effectually assist a forest or woodland haunting species. More and more severe became the winters, longer and longer, the glaciers descended lower and lower, exterminating or driving before them all living things. At last the Spotted Flycatcher, or the form which then represented this species, came to be divided into two enormous colonies—an African one and a Chinese one—the individuals of each being completely isolated from each other, summer and winter alike. During the ages that this state of things continued, the Flycatchers became segregated into two species, owing primarily to the absence of any intermarriage; the eastern race became smaller, the tail shorter, and the breast-streaks broader, or the western race became larger, with a longer tail and narrow breast-streaks. It is almost impossible to say which form now most closely resembles the ancestral species; but such are the present differences between the two races known to ornithologists respectively as *Muscicapa grisola* (the Western and British form) and *Muscicapa griseisticta* (the Eastern form). Such was the state of things at the close of this Inter-Glacial Period.

"Then came the gradual immigration north again, as precession and lower eccentricity initiated a milder climate. Age after age the journey in the spring became longer. Certain routes to and fro came to be recognized highways of passage; and so imperceptibly did the northern breeding grounds expand that the birds became regular migrants, looking upon the movement north to higher and cooler latitudes each spring as an undertaking never to be missed. Warmer and warmer became the southern haunts, stimulating and widening migration flight to the cooler temperatures prevailing near the edges of the retreating glaciers, where a suitable breeding climate could only be found.

"Let us confine our attention solely to the birds that bred in the British Islands. In the Præ-Glacial ages this area formed part of Continental Europe; a rich and fertile corner, abounding in insect life, full of haunts the Flycatcher loved. After the banishment of its race and the exile of its ancestors in Africa, the northern journey at first did not extend further than the edges of the glaciers on the Mediterranean coasts of Europe. But as these disappeared, and a warmer climate began to prevail in higher latitudes, the annual summer flight was increased. Every century the northern breeding range had increased, creeping slowly across France; higher and higher with the growing vegetation; nearer and nearer to the haunts of old. During the slow, gradual elevation and submergence that isolated Albion from the rest of Europe during Post-Glacial time, the regular spring journey across the sea became wider and wider; but with the intense and inherited love of home in their tiny breasts, the individuals that were born and bred in this district never failed to return each year. For 60,000 years or more has this species now crossed the sea, returning every season, not only to our islands, but each pair of individuals, as long as they live, come back to the exact locality of their previous nests. This long journey, gradually growing longer and longer during thousands of years, until it is now at least a thousand miles in length, has grown to be a deeply rooted custom sanctioned by the practice of ages of experience and need, and looked upon now as part of the Flycatcher's very existence!" (pp. 58-62.)

This, we think, is Mr. Dixon at his best, and we are anxious that our readers should so see him. He goes on to call it a "thoroughly demonstrable instance," which shows what his idea of a demonstration is. We do not deny that all may have happened as he here prescribes, but who knows that it did? To begin with, we may ask what proof is there of the existence on the earth itself of *Muscicapa grisola* "when the Sub-Polar regions of the northern hemisphere last enjoyed a warm, almost semi-tropical climate"? That its ancestors then lived we do not doubt, but who can tell us what they were like? What is meant by its "becoming partially nocturnal during the Polar night"? If so its eyes must since have undergone a considerable change, and that would hardly be unattended by a corresponding change in other parts of the bird's structure. But still it is a pleasing suggestion that "its conditions were easy" in those millenniums, and we hope Mr. Dixon may be right, though for our own part we cannot help fearing that the struggle for existence must have already begun. Certainly it set in at last, and those terrible glaciers drove the poor bird before them, with the effect—Mr. Dixon, we think, is to blame for not giving us the geographical details (which of course must be known to him) of the process—of dividing the species or the form which represented it, and may be presumed (though this is not mentioned) to have by that time got rid of its owls' eyes, "into two enormous colonies—an African one and a Chinese one." These were so isolated that inter-marriage between the individuals of the two portions was impossible, the remarkable consequence of which was that "the Eastern race became smaller" than the Western—a character distinctive indeed of the human races, the Pygmies excepted, now inhabiting the same lands—but with "the tail shorter"—a contradictory character, since the long tail of a Celestial is the really important part of him. We are also told that "it is almost impossible to say which form now most closely resembles the ancestral species," an unexpected confession of ignorance (the "almost" is good) after so much information, but one to which we see the necessity of bowing. However, what is the upshot of all this? And how is any "law" illustrated by it? Setting aside the vagaries on which we have just commented, it reads to us as being merely an amplification of suggestions that were tentatively and cautiously submitted in these columns more than eighteen years ago (NATURE, vol. x. pp. 416 and 459). The partiality of birds for their old homes was then, and (so far as we know) for the first time, pointed out as one possible factor in establishing migratory habit, and, as another (and equally for the first time), the growing divergence of breeding and feeding areas through climatic causes was briefly and clearly set forth by Mr. Wallace. Notwithstanding Mr. Dixon's assertions, he does not seem to have advanced the question one bit, but he has overwhelmed it in a flow of words with a great deal that is, and apparently always will be, incapable of proof. Here and elsewhere throughout this volume we are brought to face one of that school of biologists, the growth of later years, which may be called the Assertive. In some respects it is a very nice one to join. You have only got to say what first comes into your head, and all goes well. Everybody that differs from you is a fool. To some extent this school resembles that Dogmatic one which a few naturalists here and there still remember, inasmuch as the dissentient from either was regarded with the same contempt. The Dogmatists have had their day, but if we look back upon their doings, we shall see that in most cases they had something to go upon which

was not entirely assertion They were very fond of facts, and undoubtedly preferred founding their dogmatism upon them—indeed, nothing could be more distasteful than to suppose each dogma had not a sound basis In most cases the worst of which they can even now be accused is that the facts were often above their comprehension, or were understood in the wrong sense But these men would have scorned the grounding of their dogmas upon imagination They were perfectly aware (only it had not then been so neatly put) that "Imagination is the fire of Discovery the best of servants though the worst of masters." Now the Assertive school, of which in this country Mr Dixon, if he was not the joint-inventor, may be looked upon as a chief leader, rests nearly all on imagination It matters little whether there is reason behind their assertions or not, and generally, we regret to say, there is none Conjectures follow upon conjectures and are put forward for the most part as if they were serious deductions from observation It is not so many weeks since some words, that seem very applicable here were addressed to a scientific audience —

"We have had enough of the untrained writer of papers, the jerry-builder of unfounded hypotheses whose ruins cumber our field of work"[1]

Mr Dixon, with his long string of previous books, may demur to being termed a writer of this kind, but he certainly needs to be taught the meaning of the word "probable" and its derivatives When he has learned it perhaps he will use it in its fit sense With him, at present, it is in many cases to be rendered "possible," while in not a few *impossible* would be the true equivalent Now according to all etymologists, and the harmless drudges known as dictionary makers, "probable" signifies *something that can be proved* Any reader of average intellect will be able to calculate how seldom this unhappy word is correctly used by Mr Dixon It has long been a custom in certain fevers to affix an ice-cap on the patient's head whereby the burning brow is cooled, and some temporary relief afforded, but of late years, as pretty well all know, there has sprung up a small group of writers to whom ice on the brain, instead of being a soothing remedy, is a direct incentive to acts and dicts bordering upon lunacy On behalf of the Glacial Epoch, the Post-Pliocene Glacial Epoch, to be very particular, we must protest against its being constantly paraded as the greatest event in the history of the globe, to which in its momentous effects all others must give place That it produced considerable changes and especially in the geographical distribution of plants and animals none can doubt, but that it is accountable for all that Mr Dixon lays to its charge is hardly likely, and is most decidedly not "probable," since means of proof are wanting But Mr Dixon, with others of the Assertive school, is not consistent in his statements, and is apt to forget on one page what he has written on a preceding one For instance, we are told (p 33) that "From the commencement of this Glacial Epoch, the Migration of birds, as we see it at the present time, was probably initiated", and yet, only a few lines further on, our author declares "that we do not require even the occurrence of one Glacial Epoch to account for the Migration of birds," and (p 34) that "such a cause amply sufficient in every respect is to be found in the varying places of Earth's [*sic*] orbital eccentricity in combination with the precession of the equinoxes"—this statement being immediately followed by a passage, the application, or even the meaning, of which is not easy to understand —

"That these majestic phenomena are in any conceivable way connected with the migratory movements of birds seems utterly impossible, but in them the habit has its root, and the simple season-flight of a Cuckoo or a Nightingale to and fro between the shores of Africa and England is inseparably and directly connected with the erratic movement of a planet in its orbit, nay, with the constitution of a universe!"

This note of admiration is our author's own far be it from us to impair its influence

Though we have confined our remarks to the earlier part of Mr Dixon's book, we have already devoted a good deal of space to him There is, however, another point on which we must say a few words. He has thrown out a direct challenge to NATURE, and we should be sorry not to meet it That he believes in migration the whole volume shows, but there is yet left in his mind a cranny wherein lurks what we may perhaps call a "pious opinion" in favour of torpidity—as a luxury in which a lazy bird may occasionally indulge, even though that bird may be one possessing powers of flight far beyond the average He is very severe on an anonymous reviewer in these columns in that the "Theory," we use Mr Dixon's word, of Torpidity "was subjected by him to the bitterest ridicule and denounced as folly" Thereupon he favours us (pp 12, 13) with another version (substantially, let us say at once, the same as the original, but with fewer details) of the story told by the Duke of Argyll in these pages (NATURE, vol xv pp 527, 528) to say nothing of some other observations, quite irrelevant, as it seems to us, communicated by his Grace to him But further than this, he cites as an additional witness in defence of the impeached "Theory," Dr Elliott Coues, who is said to give it "all the support of his authority as an ornithologist of the highest eminence" Now we have a great respect for that gentleman, but his vast reputation fails to hypnotize us, and such support as he gave has already been the subject of comment in these pages (NATURE, vol xx p 2) He will hardly be comforted to learn that the supposition there made has been amply confirmed of late by Mr Hartert, who informs us (*Cat B Brit Mus* vol xvi p 481) that the British Museum contains five specimens of *Chætura pelagica* from Central America, beside the one before noticed from Mexico —proving that its range is much about what might have been expected Thus all the argument based on Dr. Coues's statement, that this species was "not known to winter anywhere out of the United States, nor is it found anywhere in them at that season," falls to the ground, as we are sure that gentleman will readily admit We allow that it has been very naughty of naturalists if they did prepare this pitfall for Mr Dixon, but that is not our business, and we cannot imagine they did it intentionally It is not unlikely that the Chimney-Swift flew out of shot, or too fast for them to bring it down, but they have at last succeeded in "grassing" their bird, with a result so disastrous to the "Theory" One chance

[1] British Association for the Advancement of Science. Edinburgh, 1892 Address of the President of Section H (NATURE, vol xlvi p 379).

yet remains for our author, for though "unfortunately no direct evidence of torpidity has ever come under" his own observation, the *Dundee Advertiser* of April, 1884, supplies him with another straw at which to grasp—not that the newspaper-writer saw it at all in that light, for he called the bird in question a "wanderer," which term is innocently repeated by Mr Dixon, apparently unconscious that thereby he gives up his case, and drown he must unless some one throws him a life-belt Meanwhile that of the "hibernating" bird is as desperate Deprived by the brutal sceptic of its ancient refuge in the depths of Lapland lakes, or in the crumbling banks of Persian rivers, in the mud walls of Orkney or in Irish dung-heaps, or even in nests of its own building in sea-girt Schleswig-Holstein, the *fin de siècle* Swallow desirous of enjoying torpidity has to betake itself to the security of the Bell Rock Lighthouse, and even there to excite no particular astonishment on the part of the honest men who welcomed it If they had looked upon it as the spirit of Robert Stevenson, or that Abbot of Aberbrothock whose memory was blessed by mediæval mariners, there would have been some excuse for them, but they simply regarded this Swallow as the proverbial one that doesn't make a summer—it was the 12th of March They will, we think, learn with surprise from Mr Dixon that "this bird may probably have spent the winter, dormant, near the lighthouse," while he considers "that we here have the most trustworthy evidence of a positive kind" If this does not indicate hibernation capabilities amongst certain birds, pray to what else can it be attributed?" (p 16) We leave our readers to answer this question as they please, but we fear their answer will not please him They may, however, like to know how the incident was recorded in the Migration Committee's schedule by the matter-of-fact observer —"1884, March 12th One Swallow (Swift) 4 p m. [Wind] S E, strong B[reeze] [Weather] cloudy Arrived much exhausted" No more and no less

Returning to the position whence we started we must express our deliberate conclusion that Mr Dixon, author of so many works as he may be, is no authority on the subject of Migration, which he has left exactly as he found it In the hope he entertains that his volume may form "a basis for more elaborate study and detailed research" we entirely concur On one, and that the most wonderful part of the whole business, the faculty whereby birds are enabled to perform their extended flights with such punctuality and general unerringness that the more one knows of the subject the more one is amazed at it, he is silent, for it would seem that there are even bounds to his imagination, and for this we are thankful

DOMESTIC ELECTRIC LIGHTING

Domestic Electric Lighting, Treated from the Consumer's Point of View By E C De Segundo, Assoc M Inst. C.E. (London H Alabaster, Gatehouse, and Co., 1892)

THE author of this small volume is of opinion that there is at present no literature obtainable to enable the untechnical public to form a judgment as to the suitability of applying electrical energy to meet their various requirements, and he states that at present the extended applications of electricity are largely engrossing attention, but owing to the conflicting views expressed by those ignorant or interested, there is a probability of a feeling of disgust being engendered for all things electrical in the lay mind No doubt there is a good deal of truth in this statement, on the other hand, those who take any interest in this all-important subject will soon learn enough to be able to discern that which is important and worth knowing The volume under notice has been written in order to fill this want in electrical literature, and to teach the consumer of electrical energy something of the source of the light and power he is using

It is admittedly a difficult task to make a technical subject clear to untechnical, though interested, readers, and in this case all the more so, on account of the extreme technicalities of electricity as applied to everyday requirements

The author begins at the very beginning, and in Chapters I and II deals with the lighting of rooms with gas, oil, and electricity, naturally pointing out how very soon the atmosphere is vitiated by the two former illuminants, besides the damage done to paintings, book-bindings, &c When discussing "How shall I light my house best?" the author treats of the efficiency and cost of the different illuminants, and points out that although the electric light may be the more expensive, yet the cost per lamp per hour may be fairly compared with oil or gas, because these illuminants are seldom turned completely out when a room is temporarily empty, whereas the facility of switching on and off an electric lamp must naturally save the current and effect economy

Chapter III consists of a short description of some of the systems on which electric light is produced and supplied Great diversity of opinion exists as to which is the best system on which electric energy should be supplied for public use In London two systems are in vogue, viz, The high pressure alternating current in conjunction with transformers, and the low pressure continuous current system From the consumer's point of view, so long as the high pressure current is not allowed to enter the house, it matters little what are the conditions of distribution, provided a continuous low pressure direct supply or a low pressure alternating current from a transformer station is delivered to him, except, of course, where motors are in use, and then the continuous current is a necessity For installations in the country, separate generating plant is required, and for small installations, where on the average fifteen lamps of 8 c p are in circuit at a time, the author says that the electrical energy can be economically generated by chemical means The primary battery referred to is a modified form of Bunsen, and the cost of producing the light is stated to be one penny per lamp of 8 c.p per hour No doubt such a battery takes the place of engine, dynamo, and accumulators, but it is purely a matter of opinion as to the trouble and skill required to look after these batteries, and, without taking the prime cost into account, a gas or oil engine driving a dynamo and charging accumulators to run these fifteen 8 c p lamps should not cost fifteen pence per hour. A case is known where an Otto domestic gas engine is easily driving seven and sometimes eight 8 c.p lamps, and consuming 24 cubic feet of gas per hour, at a cost of considerably under one penny per lamp, the lamps being run direct off the dynamo.

The progress of private electric lighting is simply astonishing, the gas engine being generally the motor used. Many of these engines are run by the Dowson gas, made on the spot, thus rendering a supply of illuminating gas unnecessary.

The author treats somewhat in detail the cost of electric lighting in a house, but as this largely depends on the type of pendants, brackets, &c., used, the outlay naturally varies considerably. The most serious item in the maintenance of an installation is the breakage of the lamps. The author rejoices that this monopoly of manufacture will soon expire, when competition will place better lamps on the market at half the present cost.

Taken as a whole this little book is interesting and useful. It will certainly help the uninitiated consumer to study intelligently the principles of electric lighting, and render his conception of necessary expenses when installing the light more sensible.

OUR BOOK SHELF

Grasses of the Pacific Slope, including Alaska and the adjacent Islands. Part I. By Dr. Geo. Vasey, Botanist, U.S. Department of Agriculture. 8vo, 56 plates, with descriptions. (Washington: Government Printing Office, 1892.)

THE botanists of the United States Department of Agriculture are working very energetically, and the importance of the herbarium, library, and its publications is increasing year by year. The present work is part of a series of illustrations of the North American grasses, of which we have already noticed two parts, together making one volume, devoted to descriptions and figures of the characteristic species of the South-Western States. The present part, which will constitute half a volume, is devoted to California and the Western States. Dr. Vasey tells us in his introduction that the grasses which are known to grow on the Pacific slope of the United States, including Alaska, number not far from 200 species, which is nearly twice as many as we get in the British Islands. They are all specifically distinct from the grasses growing east of the Mississippi, and also mostly distinct from the grasses of the plains and of the desert, except in that part of California which partakes of the desert flora. A considerable number of the grasses of the mountainous regions of California, Oregon, and Washington reappear in the mountains of Idaho, Montana, and the interior Rockies. The interior of California is a dry region, verging in the extreme south into the desert country, and is deficient in grasses, especially of those species which form a continuous turf. In the present publication fifty of the most interesting species are described and illustrated.

The descriptions are almost wholly the work of Dr. Vasey's assistant, Prof. L. H. Dewey. The illustrations are excellent, and are the work of various artists—F. Muller, W. R. Scholl, T. Holm, and others, and are accompanied by full dissections. The species range under the genera as follows:—Imperata, 1; Panicum, 1; Cenchrus, 1; Phalaris, 2; Hierochloe, 1; Aristida, 1; Stipa, 9; Oryzopsis, 2; Muhlenbergia, 5; Alopecurus, 7; Agrostis, 6; Calamagrostis, 10; Deschampsia, 1; Trisetum, 3; Orcuttia, 2. Only two out of the fifty species are British, *Alopecurus geniculatus* and *Deschampsia cæspitosa*.

J. G. B.

Aids to Experimental Science. By Andrew Gray. (Auckland: Upton and Co., 1892.)

THE chief interest of this little book lies in the fact that it gives a glimpse of the science teaching in one of our colonies. It is a compilation of simple experiments in mechanics, physics, chemistry, physiology and health, and agriculture, to prepare students for what is known as the Class D examination. Naturally, most of the experiments are old ones, but here and there one may gather a new idea. The portion dealing with physiology and health has nothing to do with dissection, but consists of experiments on ventilation, drainage, food stuffs, and the like. An interesting piece of apparatus, devised by Prof. Bickerton for showing the action of the lungs, is described on p. 76. All the experiments are briefly but sufficiently described, and many of them are illustrated.

Science in Arcady. By Grant Allen. (London: Lawrence and Bullen, 1892.)

THIS volume will fully maintain Mr. Grant Allen's reputation as a popular writer on science. The essays of which it consists are written in a bright, lively style, and may be read with pleasure even by original investigators, for the truths with which they deal, if not new, are at least presented from new points of view. Readers who do not profess to know much about any particular branch of science will find in these papers an excellent introduction to some of the more attractive facts and laws of the natural world. The volume includes some archæological essays, which show very effectually that an antiquary has not necessarily much resemblance to Dr. Dryasdust.

LETTERS TO THE EDITOR.

Macculloch's Geological Map of Scotland.

IN a recent article in this journal Prof. A. H. Green writes as follows:—

"Macculloch seems to have projected, but never completed, a geological map of the whole of Scotland. The materials collected by him were, however, utilized by the Highland Society in the construction of a general map in 1832."

I am sure that nothing could be farther from the wish of the Oxford Professor than to do an injustice to the memory of one of the greatest of the pioneers in British geology, and he will therefore forgive my calling attention to the following facts, which, judging from a subsequent letter in these pages, would seem not to be generally known.

During the last twenty years of his life Dr. John Macculloch was engaged on a regular survey of Scotland, and in collecting the materials for a geological map of the country. In the earlier part of this period Macculloch seems to have availed himself of the opportunities afforded to him as an official of the Board of Ordnance to carry on his valuable geological explorations. But during the latter part of the period he was regularly employed by Government to complete his geological work, and was paid by the Lords of the Treasury, who in the end published his map.

On July 28, 1834, Macculloch addressed to "His Majesty's Treasury" a series of memoirs respecting the Geological Map of Scotland, which was then completed. In these memoirs he refers to the map as being then in existence, and gives the most minute directions concerning the tints to be employed by the colourists who were to copy the map, in order that it might correspond with his original work. He also expressed his regret that the imperfect topography of the map on which his researches had to be recorded prevented the work from being as accurate as he could have wished at certain points.

Owing to delays in issuing the Government publications—not quite without parallel in more recent times—Macculloch's "Memoirs on the Geological Map of Scotland" did not appear till the year following his death (1836). The date at which the first copies of the map were issued it would probably be difficult to determine, but as to the completion of the map before July 1834,

and its subsequent issue by "the Hydrographer to the King by order of the Lords of the Treasury" there can be no doubt whatever

The first Government Geological Survey undertaken in the British Islands was that of Dr John Macculloch, and the work that he accomplished single-handed was a very remarkable one Several geological maps of Scotland, differing very widely from that of Dr John Macculloch, have been issued and withdrawn during the last fifty years, but any one who will compare the first geological map of Scotland with the latest, also "published with Government authority," will be interested to see how far the work of the early pioneer in Scottish geology has been found to be correct in most of its essential features by those who have come after him

John Macculloch's title to be the author of the first geological map of Scotland is as indisputable as are the similar claims of William Smith and Richard Griffiths with respect to England and Ireland respectively. JOHN W JUDD

Glaciers of Val d'Herens

THE two glaciers of Arolla are interesting, inasmuch as one, the Arolla, is retreating, while the other, Glacier de Zigiorenove, is advancing This has been going on for twelve years, according to the report which appeared in NATURE (vol xlvi p 386), by Dr Forel, dealing with Alpine glaciers and their changes

Having visited these glaciers last summer with the object of observing the effect of their respective movements upon the morainic accumulations in front, I think a brief account may be worth recording

The Arolla glacier occupies the head of the valley, and is fed by the snow from Mont Colon and the fields of nevé extending towards Mont Brulé The Zigiorenove glacier is one mile further down the valley, but does not descend so low as the Arolla glacier by about 300 feet It receives its main supply from the Pigne d'Arolla, a mountain which rises immediately above the glacier, and is conspicuous by its massive snow-cap This glacier is not only nearer to its supply, but descends at a steeper gradient than the Arolla glacier

This may in some measure account for the former advancing while the latter is retreating, or, more correctly speaking, melting backwards I was informed by local guides that the Arolla glacier has been swelling behind for some years, if this be correct, and the seasons remain normal, then, in a short time, this glacier must advance also, in other words, being longer or further away from its feeding ground, the extra supply has not yet had time to reach its extremity Appearances at the end of the glaciers are in themselves quite sufficient to indicate their respective movements, the snout of the Arolla glacier is buried in its own debris, composed of rocks and loam borne upon or concentrated to the surface as the ice melts This debris is being constantly shot down grooves or water courses furrowed in the sloping end or side of the glacier At the bottom of these spout-like grooves conical shaped mounts are formed, one behind another, as the ice melts backwards, resulting in a moundy, zigzag arrangement constantly seen lower down the valley, many miles away from existing glaciers, and can be seen also in many of the higher valleys of North Wales.

The advancing Zigiorenove glacier, instead of being buried in debris, turns up in shell-like flanges, exposing its under surface in its endeavour to climb over, rather than push forward, the loose rocks in front, a part of this loose material only is pushed forward, forming a small bank, which in no place exceeded 5 feet in height, up which the ice mounts with the shell-like flanges projecting beyond, the under part of these projections being fluted into a perfectly symmetrical pattern

In some way the projecting rocks forming the glacier bed produced these convolutions, but whether by cutting, melting, or by the ice crystals flowing round each side, I was unable to determine, but I may state there was no appearance of cutting or grinding which would necessarily leave behind the shavings or ice particles cut out or ground off, and little or no water was present as if from melting. We had much snow for three days, with a total absence of sunshine, the atmosphere at mid-day, when making these observations, registered 38° F Appearances rather suggested the idea that the ice crystals were displaced in a similar manner to water in a rapid river when it meets with obstructing boulders in its bed

Climbing up one of the old lateral moraines, for there are several, the glacier is seen to be encroaching laterally as well as longitudinally, it soon extends to the base of the inner moraine, and then climbs upwards in a similar manner as it advances in front by turning up its edges, carrying upwards a few loose rocks in front, but without materially disturbing the moraine itself Higher up it reaches the top of this moraine, and then rises above it like a wall, having caused the loose rocks it had borne up to roll down into the valley between the inner and outer moraine, with masses of ice broken off the edge of the glacier

As far as I am able to ascertain, by creeping under the flanges the glacier slowly spreads out the bank which it had pushed up in front as it advances into a more even bed to travel over, but my observations were restricted to a few yards owing to the contraction of the sub-glacial space between the ice roof and the floor I was much impressed by the fact that the glacier did little in exerting that force which might be expected from such a power behind, in the way of ploughing through or removing such comparatively trifling obstructions as loose rocks or moraine banks

It is evident from the various ages of moraines that the lower parts of those glaciers have fluctuated considerably during recent times, but the line of demarcation between these minor fluctuations and the period after these lateral valley glaciers had been confluent with the main Valais glacier, and were retreating backwards, is very marked Beyond two miles down the valley from the Zigiorenove glacier no striæ from the trunk glacier could be found, but at this distance it suddenly appears with *fresh glaciated forms*, *precisely the same phenomenon* was noticed in the neighbouring Val d'Anniviers, as if this were the limit of the more recent fluctuations

At the Col de Bertol, 4500 feet above Arolla, or about 11,000 feet above sea level, there are no indications of glaciation, ancient or modern, above the surface of the snow; so it would appear, however much the ice level has varied below, at this dividing ridge it has always remained the same, or, in other words, it has been dispersed by wind or ice movements to lower levels at a rate equal to deposition, when the snow line was low enough to allow the ice to travel down the Val d'Herens, the higher ice streams would simply run down upon its surface, instead of descending as low level glaciers or mountain rivers, as at present

Eastbourne House, Sutton Coldfield

Ancient Ice Ages

MESSRS BLANFORD, in their letter (NATURE, p 101) called forth by Dr Wallace's notice of a palæozoic glacial conglomerate in Victoria, Australia, say —"It has become an accepted article of faith amongst most European geologists that no ice-age occurred before the last glacial epoch" There is no doubt that the tendency of opinion has been in that direction, notwithstanding the evidences to the contrary brought forward by Dr. Blanford and others The late Sir Andrew Ramsay was the first, so far back as 1855, to suggest that the Permian conglomerate of Abberley and the Clent hills was an ancient glacial deposit Although this reading was accepted by so cautious a philosopher and critic as Sir Chas Lyell ("Principles," 10th ed, vol i p 223), the idea has languished from disfavour Having devoted a considerable portion of the last twenty years to the study of glacial phenomena, I early this year paid my first visit to the district The best section I saw is an excavation at Abberley in what may be called boulder gravels, and, except for its prevailing red colour, the deposit, *if dropped down on the coast of Wales*, would, in general appearance and arrangement of the materials, be undistinguishable from many of the glacial deposits to be found there Many of the stones have flattened faces, and in general shape resemble glaciated boulders, but the striæ, so far as I could observe in the limited time at my disposal, were not very pronounced Since then I have found a deposit of glaciated gravels on the top of the Screes, Cumberland, 1600 feet above the sea, which on comparison with the specimens brought home from Abberley enables me to understand the latter better The volcanic rocks of the lake district of which these gravels are composed break up into very similar shapes, and are planed and striated in a very similar way to those of Abberley I also brought home from Abberley two specimens of the "paste" which fills up the interstices of the finer gravel

On washing and riddling this clayey matter, well waterworn and smooth gravel was separated from it up to about the size of a bean, and on many of these minute pebbles, with the aid of a microscope of low power, beautifully developed striæ are to be seen, sometimes on more than one face This latter fact appears to have been unnoticed before The conclusion I have come to is that Ramsay had reasonable grounds for his belief in this being a Permian glacial deposit, and think that if he had given more details in his otherwise able paper, geologists would probably have followed him more freely

Park Corner, Blundellsands, December 5

The Earth's Age

As Dr A R Wallace's "Island Life" may be regarded as one of the best authorities on its subject, it appears desirable that any errors in it should be pointed out, lest any of its numerous readers should be misled

In Chapter X (2nd edition, 1892) is an estimate of the earth's age based on the following data —Land area of globe, 57,000,000 square miles, coast line, 100,000 miles, width of shore deposits, 30 miles, hence area of shore deposits, 3,000,000 square miles, hence rate of deposition 19 times as fast as that of mean rate of denudation, which latter is taken to be 1 foot in 3000 years

Thickness of stratified rocks 177,200 feet, hence time required for deposit 28,000,000 years This last result is taken to be approximately the earth's age

It appears to me that Dr Wallace's data warrant no such conclusion, for, in the 28,000,000 years in question, all that would have been deposited would be a thickness of 177,200 feet of rock, over an area of only 3,000,000 square miles, whereas, what has to be accounted for is an area of 57,000,000 square miles (neglecting igneous rocks and sedimentary deposits beneath existing seas) of the same thickness Therefore, so far from Dr Wallace's data leading to 28,000,000 years as the earth's age, they actually lead to a result 19 times as great, viz 532,000,000 years

Sir A Geikie's estimate is (NATURE, vol xlvi, p 322), 100 to 680 million years Personally, I think, the method of taking maximum thicknesses of deposits unsatisfactory, for it assumes that every formation was deposited, with its maximum thickness, over the whole land area of the globe The absurdity of this supposition is obvious The only defence of it is that it is held to make an ample allowance (of unknown amount) for repeated denudation It would, perhaps, be better to ascertain the actual thickness of a great series of successive formations, say in the Colorado Cañon and other regions, and from such data to estimate the total *average* thickness This estimate, of course, would allow nothing for repeated denudation, but would enable one to form an idea of the earth's *minimum* age

BERNARD HOBSON.

Owens College, Manchester, December 5

I AM glad that Mr Hobson has formulated his difficulty as to the measurement of geological time by the comparative rates of denudation and deposition, because it shows that I cannot have explained my views as clearly as I thought I had done, yet on again reading over pp 217–223 of "Island Life," I can hardly understand how he has missed the essential point of the argument Fortunately, there is no dispute as to the data, only as to the conclusions to be logically drawn from them

Mr Hobson says that I account for a deposit of 177,200 feet (the supposed thickness of all the stratified rocks) over an area of 3 000,000 square miles (the estimated area over which at any one epoch stratified rocks are being deposited) in 28,000,000 years (the deduced estimate of known geological time), and then adds: "Whereas, what has to be accounted for is an area of 57,000,000 square miles *of the same thickness*" (my italics) This seems to me a most amazing misconception, for it means that every single formation and every stratum or member of each formation, was deposited to the same average thickness over the whole land surface of the globe (area 57,000,000 square miles)! And this implies that at every successive period, from the Laurentian to the Pliocene, the conditions of denudation and deposition were totally different from what they are now, since at the present time it is demonstrable that the area of deposition of continental debris is only a fraction of the whole continental area It implies further, that during each geological period the whole of the existing land area must have been, either at once or in rapid succession, sunk beneath the sea in order to allow of its being all covered with each successive formation—an amount of repeated upheaval and depression which hardly the most extreme convulsionist of the old school would have postulated I cannot make the matter clearer, and trust that on further consideration Mr Hobson will admit that his objection is invalid

ALFRED R WALLACE

The Colours of the Alkali Metals

IN NATURE (vol xlvii p 55) is a communication by Mr G S Newth, entitled "Note on the Colours of the Alkali Metals."

I write to call attention to my article on "The Colour and Absorption-Spectra of Thin Metallic Films, and of Incandescent Vapours of the Metals, with some observations on Electrical Vitality," published in the *American Chemical Journal* (vol xiv p 185) and reprinted in the *Chemical News* (vol lxvi p 163), which gives the method employed by Mr Newth, as well as other methods for obtaining metals in thin films

In it attention is also called to the fact that the colour of the film of the metal and the colour of the vapour are widely different

Mr Newth, however, succeeded in getting a film from sodium on glass, while I did not, and his success was probably due to the use of a higher vacuum than I employed He also obtained a rubidium film

In my paper I called attention to the similarity in colour of the film by transmitted light and that of the *incandescent* vapour which is very striking in many cases In this respect the film of rubidium as obtained by Mr Newth follows the rule fairly well, but the film which he got from sodium is exceptional, as according to the analogy furnished by other metals it should be yellow The presence of potassium, however, might cause the green colour which he observed, by the combination of yellow and purple

Nashville, Tenn, December 2

Osmotic Pressure

IN an article on osmotic pressure, in NATURE (*ante*, p 103), Mr Rodger very truly remarks that "at present the attitude of the prominent upholders of the new theory [of solutions] is one of indifference as to the exact mechanism of osmotic pressure The numerical agreement between the measurements on solutions and those on gases is regarded as ample justification for considering dissolved substances to be in a pseudo-gaseous condition" Such an indifference is surely to be regretted from any truly scientific point of view, especially as those explanations which have been given of the mechanism of osmotic pressure have been based on the supposition that the dissolved substance is in a *veritable* and not merely *pseudo* gaseous condition There are, however, many reasons for supposing that while the dissolved substance may for many purposes be regarded as analogous to a gas, it must in reality be in a very different condition, and that osmotic pressure is not due to the bombardment of the free molecules of the dissolved substance against a diaphragm through which they cannot pass The impenetrability of the diaphragm to certain molecules can scarcely be attributed to any other cause than that the molecules are too large to pass through the interstices of the former, and it is scarcely conceivable that the molecules of water which do pass through can be much smaller than the molecules of simple salts, which do not pass through, still less that they can be smaller than the single atoms into which these salts are said to be dissociated

A very simple experiment, which I mentioned some time ago in the *Ber d deutsch Chem. Gesell* (24, 3639), appears to settle definitely against the view that osmotic pressure is due to impenetrability to the dissolved substance A solution of propyl alcohol and water was put into a porous pot and immersed in a vessel of water, the water passed through the pot to the solution, and this, according to the usual explanation, would show that the pot was impermeable to the propyl alcohol The same solution was then immersed in a vessel containing propyl alcohol, when the alcohol was found to pass through to the solution, from which we should have to draw the diametrically opposite conclusion that the pot is impermeable to the water The true conclusion obviously is that the pot is impermeable, neither to the alcohol alone, nor to the water alone, but to the solution of these in each other, and that the molecules composing this solu-

tion must be larger than those of either of the two substances when separate, the solution consisting of compounds or hydrates of the two I showed, moreover, in the paper above referred to that the hydrate theory of solutions was quite capable of accounting for and explaining the fact that the dissolved substance may for many purposes be regarded as being in a quasi-gaseous condition in weak solutions, and that calculations based on the idea of its being truly gaseous would yield very nearly correct results

The hydrate theory will also, as I showed, give an explanation of the fact that electrolytes will give abnormally high osmotic pressures, and that the magnitude of these pressures can be calculated from their electric conductivity and the explanation based on this theory also obviates many of the objections to which the idea of dissociation into ions is open More over, the only critical experiment which, as far as I know, has ever been made to test the validity of the dissociation hypothesis, gives an unequivocal answer against it, and in favour of the hydrate theory When, for instance, sulphuric acid is dissolved in excess of water, it is represented by the dissociationists as splitting up into its ions, so that the solution will contain more acting units (ions and molecules) than the acid and water together contained before they were mixed whereas, on the hydrate theory, combination will have occurred, and there will be fewer acting units present The number of acting units may be ascertained by observing the depression produced by the solution on some other solvent, such as acetic acid (that is, by using the very method which the dissociationists use to prove the supposed dissociation of substances), and when this is done it is found that the sulphuric acid solution contains *fewer*, instead of *more*, units than the acid and water separately

Even if the above were the only arguments to be urged, it is evident that although the idea of the dissolved substance being gaseous and often dissociated may be a good working hypothesis for the directing of investigation, it can scarcely be accepted as a true theory of the nature of solutions

SPENCER PICKERING

On a Supposed Law of Metazoan Development

IT is difficult not to feel disappointed that Dr Beard has given only "a preliminary sketch by way of clearing the ground" (NATURE, vol xlvii p 79), in place of "producing the full argument" for a law in the existence of which he has by "observation and reflection" been led to believe For it is not easy to gather from his sketch how he is able to apply a universal law to so varied a series of events and phenomena such as he mentions, and at the same time to point out "the analogy which obtains between the suggested mode of Metazoan development, and the accepted fact of an alternation of generations in the life histories of all plants above the lowest Thallophytes" For in the higher plants the alternation of generations referred to occurs with constancy as regards period of life history, and varies only slightly within the limits of the same group

Dr Beard alludes, I presume, to one form of alternation of generations—that of sexual with asexual generation only, or Metagenesis. This he asserts constitutes a general law in the development of Metazoa.

In a sense this may be true enough If, for instance, we regard the division of each cell as a new asexual generation, then Metagenesis is a very constant phenomenon amongst Metazoa. In this case the life history of a Metazoon consists of a sequence of thousands of asexually produced generations alternating with one sexually produced generation, which gives apparently a stimulus for another run of asexual generations in which polymorphism and division of labour are exhibited in extraordinary complexity and beautiful harmony

But this is not at all what Dr. Beard means. The series of instances which Dr Beard gives, or system of "nursing" as Steenstrup termed it, is at most a series of disconnected phenomena of frequent occurrence, and not a law

Because most Metazoa possess eyes, it is not therefore a law of Metazoan development that eyes should be developed. Diversity in form, number, and time of appearance of eyes, is sufficient to show that the law cannot exist, so also is it in the cases of nursing to which Dr Beard alludes, and on which he bases his argument

It seems to me that no "law" of alternation of generations in Metazoa can be "enunciated" unless there is evidence forth coming of its constant action at corresponding periods in the life histories of all animals of different groups, and in a closely similar manner in individuals of one and the same group. Also a law of such a nature, if it is to be found to act universally amongst Metazoa, must surely have come into action at a very early period in the evolution of Metazoa

Metagenesis is of constant if not universal occurrence in the cycle of life of Protozoa. A long series of generations produced asexually is followed by a generation produced sexually, that is, a generation produced by the conjugation of two individuals, this is followed again by another long series of asexually produced generations, and so on If this is so constant among unicellular organisms of the present day, it is not very unreasonable to suppose it was common among the protozoan ancestors of the Metazoa and of the Plants If we are to find any form of Metagenesis as a *universal phenomenon* in the Metazoa, it must be to the most protozoon-like stages of development of the Metazoon that we should look

There is but one strict meaning to the phrase sexual generation, and that is a fusion of two cells If Metagenesis means anything it means the alternation of a generation resulting from the fusion of two cells, with one or more generations resulting from the division of cells

This we can perhaps find in the protozoon-like stages of Metazoan development, and in a way analogous to the alternation of generations among plants

Spermatozoon and ovum fuse and form the fertilized ovum which is the true sexually produced generation This produces by division a vast number of cells, and if we regard these as a number of generations then Metagenesis is obvious enough But it is no more metazoic—if I may use such a word—to call the whole animal resulting from the segmentation of the fertilized ovum, the sexually produced generation

This generation buds off the immature ovum This is really the "Primitive ovum" of the embryo I see no reason why this may not be regarded as a distinct asexually produced generation—like the formation of the spore of the plant

The immature ovum divides into two cells—first Polar body, and more mature ovum The more mature ovum divides into two cells, namely, second Polar body and mature ovum It does not materially affect the argument whether we should regard these two processes as two separate consecutive asexually produced generations, or as one asexually produced multicellular generation If we take the latter view, then the maturation of the ovum is more analogous to the prothallus stage of the life history of plants

In either case the result is the formation of the mature ovum, comparable to the oosphere of plants

The mature ovum fuses with the mature spermatozoon, and the sexually produced generation recurs, and the cycle of development is completed

I cannot help thinking that if Dr Beard wishes to discover a law of Alternation of Generations applicable to the whole of the Metazoa, he will find a more favourable hunting ground amongst those stages of development at which the several groups of Metazoa approximate, than amongst those stages where they are farthest apart, and also Dr Beard will find the analogy between the supposed Metazoan law and the accepted law of the vegetable kingdom closer than he could ever hope to find it if he continues his present line of search

If the above theory of the cycle of Metazoan life can be considered tenable, we see that both in the Higher Plants and in the Metazoa there are constantly alternating "sporophyte" and "gamophyte" generations, and further, we can find evidence, as we should expect to do, of the origin of such a universal phenomenon in the single celled or protozoan life, where the continuance of the species may be secured in both these ways, namely, by the formation of asexually produced spores, and as a consequence of cell fusion, *i.e* conjugation

RIC ASSHETON

Oxygen for Limelight

THE employment of oxygen for limelight and other purposes has increased enormously since the commercial introduction of the Brin method, by which the gas is separated from atmospheric air by a now well-known chemical process The gas so obtained is practically pure, analysis showing that as now supplied by the Brin companies it contains on an average 95 per cent of oxygen, the remaining five per cent. consisting of inert nitrogen.

The success of this comparatively new industry has been so marked, that, as a natural result, competitors with rival processes have come forward. Some of these met with failure at an early stage of their career, but others are supplying oxygen to the public. This is by no means a state of things to be deplored from the consumer's point of view, if the product from the one source is as good as the other, for benefit generally arises from healthy competition. But when the rival product turns out to be not oxygen, but a half and half mixture of oxygen and air, with a slight excess of the latter, the competition is of a decidedly unhealthy character, and is correspondingly bad for the consumer. I recently obtained a sample of gas from a dealer, which on testing (with a Hempel absorption pipette, charged with metallic copper and ammonia) I found to be a mixture containing only 60.6 of oxygen. I next tested the illuminating value of this highly diluted oxygen with a limelight jet, and for sake of comparison, placed by its side a precisely similar jet supplied with Brin's oxygen, and, as might have been expected, the light given by the former was little more than one-half as intense as that afforded by the latter. With the good oxygen the lime cylinder was quickly pitted, whilst the other showed no symptom of destruction. It is also to be remarked that the consumption of the diluted gas was, for a given period, about one-third more—striving with both jets to get the best possible light—than that of good oxygen. On the same principle a mountaineer at a high altitude will pass more (rarefied) air through his lungs than he will when he is in the valley breathing that which contains the normal quantity of oxygen.

As this matter is of great importance to many workers, I trust that you may be able to find room in your valued publication for these words of necessary caution.

T. C. HEPWORTH

45, St. Augustine's Road, Camden Square, N.W., December 6.

THE STAR OF BETHLEHEM

IN the *Astronomical Journal* of November 26 we find the second of two very interesting articles written by Mr. J. H. Stockwell, bearing on the chronology of certain ancient events. In the introduction the author discusses and sums up some of the more important and historical dates which he has determined by calculations of ancient eclipses. He next refers to the help which may be obtained in the same direction by means of calculations of conjunctions of the planets, and quite appropriately to the present season points out that the appearance of the star of Bethlehem may have been due to the conjunction of the planets Venus and Jupiter, instead of Saturn and Jupiter, as was suggested on incomplete data by Kepler nearly three hundred years ago. We cannot do better than lay this part of Mr. Stockwell's communication before our readers.

"Although the heliocentric conjunctions of the planets occur with a considerable degree of regularity, and are also very easily calculated, the geocentric conjunctions are subject to many inequalities in the periods of their successive occurrences, so that it requires somewhat elaborate computations to determine accurately the character of any geocentric conjunction of two planets which occurred in ancient times. On account of the frequency of planetary conjunctions, and the indefinite manner in which they are usually described, it becomes a matter of very great difficulty to identify any particular conjunction unless it is associated with some other event whose data can be independently determined. A remarkable case of this character is given in the Bible, for Matthew informs us in the days of Herod the King 'there came wise men from the East to Jerusalem saying, "Where is he that is born King of the Jews? for we have seen his star in the East, and are come to worship him."' From the subsequent inquiries and mandates of Herod the King concerning the time when the star appeared, we are led to infer that its appearance took place within two years preceding the death of Herod, and it has been sought to explain the appearance of the star by means of a conjunction of the planets—the Creator employing celestial phenomena to proclaim 'the good tidings of great joy, which shall be to all people.'

"The illustrious Kepler was the first to suggest that the star of the wise men might be explained by means of a conjunction of the planets Jupiter and Saturn, and he even undertook to calculate the times when such conjunctions took place. Much has been said and written on the subject of the 'star of the wise men' during the past few years, but no important contribution to the natural history of the star has been made since the days of Kepler, nearly three hundred years ago. But the supernatural history and functions of such a star have been discussed in a very able and interesting manner by many writers in theological, literary, and semi-scientific periodicals during the past twenty years, and perhaps nothing of interest and importance can now be added to what has already been published on that subject.

"I find, however, that Kepler overlooked one important element of the problem in his calculations, and consequently left the natural history of the problem in an incomplete and unsatisfactory condition. I shall therefore here attempt to complete more fully what Kepler began, and show that the Biblical narrative concerning the 'star in the east' is better satisfied by a conjunction of Venus and Jupiter than by any of the conjunctions computed by Kepler.

"We have already seen that the death of Herod took place early in the year B.C. 4, and if we can now show that there was a very conspicuous conjunction of two bright planets, visible only in the east, within two years preceding that date, the hypothesis that such conjunction was the event referred to in the Biblical narrative will at least be rendered plausible, if not entirely legitimate; and for this purpose I have here undertaken the calculation of all the conjunctions of the planets which took place near that epoch. I shall first enquire whether there was a conjunction of the planets Jupiter and Saturn about that period of time which would satisfy the required conditions. The mean interval between two heliocentric conjunctions of Jupiter and Saturn is 7253.4638 days; and they were in mean conjunction B.C. 6, January 30. Now the time of true heliocentric conjunction may differ from the time of mean heliocentric conjunction by 241 days, on account of the inequalities in their elliptic motions, and by 23 days more by reason of the great inequalities of long period in their mean motions. But the time of geocentric conjunction of Jupiter and Saturn may differ from the time of heliocentric conjunction by 102 days; so that a geocentric conjunction may occur one whole year before or after the time of mean heliocentric conjunction. In the present instance I find that the true heliocentric conjunction took place B.C. 7, September 23, which is 129 days before the mean heliocentric conjunction; and that there were three geocentric conjunctions during the year B.C. 7, which took place as follows:—

"The first conjunction took place June 7, in which Saturn passed 1° 4′ to the south of Jupiter; the second conjunction took place September 18, in which Saturn passed 1° 2′ to the south of Jupiter; and the third conjunction occurred on December 15, in which Saturn passed 1° 8′ to the south of Jupiter.

"In the first conjunction the planets would have an elongation of about 73° to the westward of the sun, and would be seen during four or five hours in the east in the morning. The second conjunction took place near the time of opposition with the sun, and would be visible during the whole night, so that it could not properly be designated as a star in the east any more than a star in the west. In the third conjunction the planets would have an elongation of about 84° to the eastward of the sun, and could therefore appear only as evening stars.

in the west Moreover, Saturn is not an especially bright planet, and consequently no one of these three conjunctions could have been very conspicuous in the heavens The first conjunction was the only one that was visible in the east, but it occurred nearly three years before the death of Herod, it could hardly be said to satisfy the conditions required by the narrative No other conjunctions of Jupiter and Saturn could possibly occur till about twenty years later, so that we may conclude with a light degree of probability that the phenomenon alluded to in the Bible was not occasioned by a conjunction of Jupiter and Saturn Since the planet Mars is a conspicuous object when near its opposition with the sun, it may be well to inquire whether a conjunction of Mars and Jupiter might not occasion the phenomenon referred to But since Mars is conspicuous only near its opposition with the sun, it is evident that any conjunction when in that direction would appear as a star in the west as much as in the east, and consequently it would not fulfil the required conditions There was, however, a conjunction of Mars and Jupiter on March 5, B C 6, but at that the planet's elongation was only 18° to the eastward of the sun, and consequently could have been visible only in the west But Mars was then so far from the earth, and so nearly in conjunction with the sun, that the conjunction would be wholly invisible At the same time Saturn was not very far from Jupiter, and hence it was said there was a triple conjunction of the planets Mars, Jupiter, and Saturn in the spring of B C 6

"It is evident without calculation there could be no conspicuous conjunction of Venus and Mars at any time, because Mars is not a conspicuous planet unless its elongation from the sun be greater than the greatest elongation ever attained by Venus, so that it would be a waste of time and labour to enter into the computations of any such conjunctions

"It now remains to inquire whether the two brightest planets of the solar system, Venus and Jupiter, might not have been in conjunction within a short time before the death of Herod, and constitute the phenomenon alluded to in the biblical narrative, for it was the beautiful phenomenon presented by these two planets when in conjunction last February that suggested this investigation Now the conjunctions of Venus with the sun occur with great regularity at intervals of about 584 days, while those of Jupiter at intervals of 399 days Moreover, it may easily be shown that all geocentric conjunctions of Venus and Jupiter must take place within about 60 days before or after Jupiter's conjunction with the sun Therefore, by tabulating the times of Jupiter's conjunction with the sun, we have only to investigate the longitude of Venus for a period of 60 days before or after that event in order to determine whether a conjunction of those planets will then take place Now I find Jupiter was in near conjunction with the sun B C 6, March 29, while Venus was in conjunction on the preceding November 5, or 144 days earlier than Jupiter Venus was therefore past her greatest western elongation, and was moving towards her superior conjunction, and she would overtake Jupiter on May 8, when their mutual elongations from the sun would be 27° 44′ to the west At that time the heliocentric latitude of Venus and Jupiter were 3° 21′ and 1° 20′ south, while their geocentric latitudes were 1° 40′ and 1° 8′ south respectively It therefore follows that at the time of their geocentric conjunction Jupiter was only 32′, or about the angular breadth of the moon to the northward of Venus, and as they were then to the westward of the sun, they would be visible only as a star in the east a couple of hours before sunrise. These two brightest planets in the sky would therefore at the time of conjunction, B C 6, May 8, be apparently very close together and produce a striking and beautiful appearance The date also at which it took place being about 50 days less than two years before the death of Herod, harmonizes well with the spirit and other conditions of the narrative, for it is probable that the mandate for the slaughter of the children of two years old and under was issued some months before his decease, and the limit of two years would leave an ample margin for any uncertainty as to the time of the appearance of the star as related by the Magi

"There were no other conjunctions of Venus and Jupiter until the year B C 2, or nearly two years after the death of Herod, when there were two conjunctions, one of which occurred on August 31 and the other on October 4 The first of these was invisible on account of being too near the sun, but the second took place when Venus was nearly at her largest elongation to the westward of the sun

"If the preceding calculations, and the references based on them, are correct, it follows that Christ was born as early as May in the year B C 6, and if He was crucified at the time of the paschal full moon, which occurred on a Friday, it must have taken place on April 3, in the year A D 33 And since any given phase of the moon is repeated on the same day of the week, and also within two days of the same time of the year, at intervals of 334 lunations, or 27 years, it follows there was no paschal full moon on a Friday between the years A D. 6 and A D 60, except the one on April 3, A D 33, whence it would seem to follow that Christ was thirty-eight years old at the time of His crucifixion and death, and this would vindicate the sagacity of the Jewish doctors, who had recently affirmed that He (Jesus) was not then fifty (forty) years old"

FUJISAN[1]

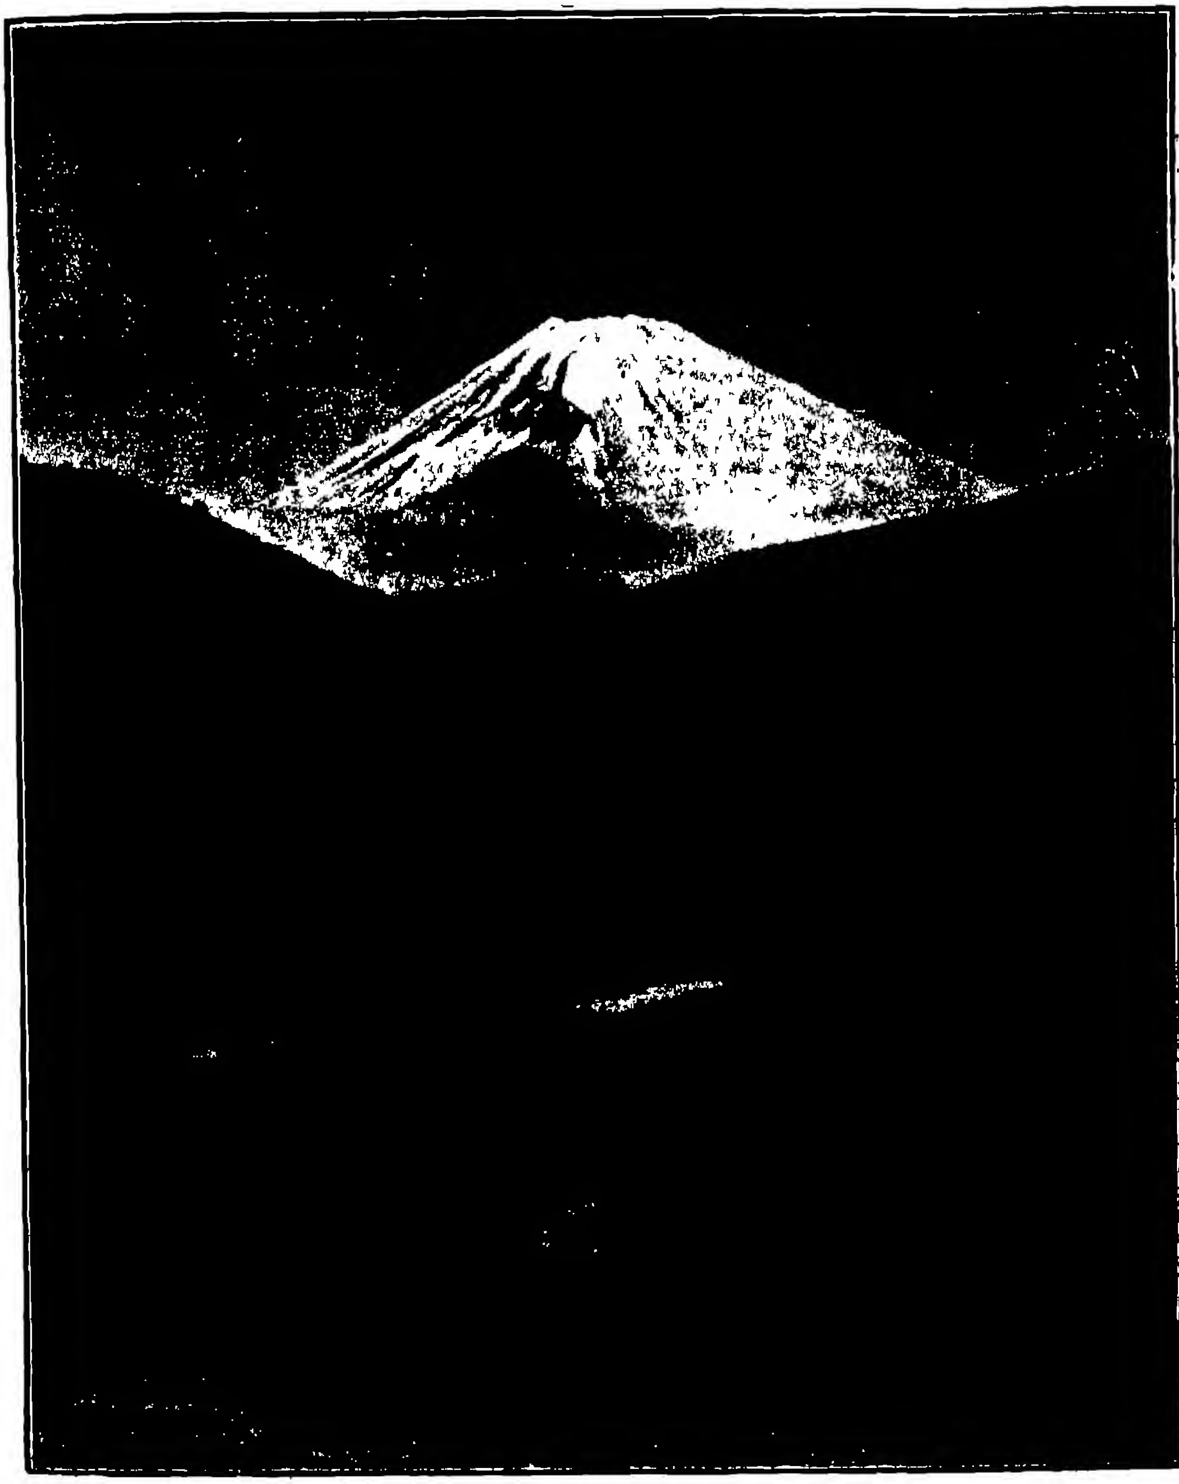
ALL who remember the beautiful plates illustrating the volume on "The Great Earthquake of Japan, 1891," which was issued by the same authors a few months ago, will welcome the first instalment of a work which promises to illustrate, in a manner worthy of the subject, the magnificent volcanic phenomena of Japan The present part contains ten plates, and is devoted to the illustration of the most famous and beautiful of all the Japanese volcanoes—Fujisan The number of parts that the authors will publish will depend partly, we are told, on the encouragement they receive, and partly on the number of photographs that they have been able to secure during the past summer

The photographs in the present part, which are all reproduced as permanent collotypes, 11 inches by 8 inches in size, are exquisite examples of what can be accomplished by this method of illustration, and show that Japan is certainly not behind any country in the world so far as the resources of the publisher go Where all are so excellent, it is difficult to select any particular plate for especial praise, but one of the most remarkable is certainly Plate II, which gives a view over the great cloud-banks as seen from the summit of Fuji Nothing can be more striking than the manner in which the effect of the great fleecy masses of vapour are reproduced, and here nothing whatever is lost from want of colour The plate of greatest scientific interest is perhaps the last, which shows the interior of the crater of Fuji—a great pit 600 to 700 feet deep, with perpendicular walls The sides are built up of rings of variously-coloured rocks, while snow rests in the sheltered hollows The remaining pictures illustrate the sacred mountain as seen from different points of view, the graceful curves of its outline, the variation in the distribution of snow on its flanks, and the

[1] "The Volcanoes of Japan Part I Fujisan" By John Milne, F R S, Professor of Mining and Geology, Imperial University of Japan, and W K Burton, C.E., Professor of Sanitary Engineering, Imperial University of Japan Plates by K. Ogawa. (Yokohama, Shanghai, Hongkong, and Singapore Kelly and Walsh, Limited, 1892)

character of the foreground, giving rise to great diversity in these eight pictures

As an example of these beautiful views, Plate IV —



"Fujisan from above Hakone"—has been reproduced, although necessarily much of the delicacy of the original has been lost in the process by which it has been copied.

"In the foreground, looking like a river, is the Lake o Hakone, at the back of which are hills some 4000 feet high At the lowest gap in these hills is the Otome pass. In the background, overlooking both lake and mountains, is the upper part of Fuji This portion of the mountain is particularly conical, with sides sloping at an angle of

30°, its logarithmic sweep being lost behind the intervening mountains. The almost triangular notch in the snow-cap may possibly represent the scarp that is supposed to have been formed by the great earthquake of 1891, causing a strip of ground in unstable equilibrium to slip downwards." The reader should compare this view with that given in Plate IX., which shows the lake, with the reflection of the mountains behind, and the snow-covered Fuji rising in the background. This plate, and the view, Lake Kawaguchi, given on Plate V., are so delicate and faithful in their portrayal of water and atmospheric effects as to defy reproduction.

No attempt has been made by the authors to produce a scientific treatise, the information contained in the text being of a popular character, and the reader is referred to the Transactions of the Seismological Society of Japan for more detailed information on the subjects treated of. It is nevertheless true that the text published with these plates contains, as the authors claim for it, information not readily obtainable from other sources. The introduction gives a sketch of the volcanic phenomena of the Japan and Kurile Islands, in which we are informed that the number of volcanoes still preserving their form, and with distinct craters, is one hundred, distributed as follows:—In the Kuriles 23, in Yezo 28, in Honshiu 36, and in Kiushiu and the Southern Islands 13. Of these no less than 50 emit steam, while 39 are distinguished by their beautiful and graceful outlines. The number of great eruptions of which there is any published record is 233, the greater frequency, as with earthquakes, having been during the colder months of the year. One line of vents, which is more than 2000 miles long, begins in Kamsatka, passes through the Kuriles, Yezo, and down by Honshiu to the ever-smoking Asama. Here it is joined by a line branching away to the south-west, which runs through the great Fujisan and Oshima, till it reaches the Ladrones, a distance of 1200 miles. The last line begins at, or near, the gigantic crater of Mount Aso, and extends 1300 miles through Formosa to the Philippines. Extremely basic rocks are rare, but so far as observations have gone, it may be said that the lava poured out from the northern vents is more acid in composition than the southern. All are magnetic, and lavas that will turn a compass-needle through 180° are not rare. By their decomposition, the soil of the country is in many places so filled with grains of magnetite, that a magnetized knife passed over the gravel of a garden path will be covered with a brush of this unoxidizable material.

The twelve pages devoted to the description of Fujisan are replete with interesting information. The word Fuji is said (on the authority of the Rev. John Batchelor, of Sapporo) to be a corruption of the Ainu word *Huchi*, which is the name of the "Goddess of Fire." Professor Milne ascended the mountain in 1880, and found that it was not quite extinct, as is usually supposed, for small quantities of steam were detected by him issuing through the ashes on the eastern side of the mountain just outside the lip of the crater. Von Fritsch and Ludecke have shown the lavas composing Fuji to be dolerites, and analyses by several chemists are given in this work. The beautiful and symmetrical outlines of the mountain are well known, but on the south side of the mountain there is an excrescence, at a height of 9000 feet, which was produced by the last great eruption in 1707. The recorded eruptions of the mountain are as follows:—B.C. 301, 294, or 286, and A.D. 799, 802, 864, 937, 1021, 1082, 1329, 1560, 1627, 1649, 1700, and 1707. Professor Milne records the interesting observations made by him with a tromometer or tremor-measure during a stay of five days on the top of Fuji. These observations tend to prove that the great mass of the mountain actually yields to force of wind playing around its summit. The height of Fujisan is proved by various observations to lie between 12,400 and 12,450 feet.

The authors are to be congratulated on the excellence of this first instalment of a work which promises to be one of great scientific value. J. W. J.

THE GALILEO CELEBRATION AT PADUA

THE celebration of the three hundredth anniversary of the day on which Galileo began his labours as a Professor at the University of Padua was even more successful than had been anticipated. Its success was in every way worthy of the large number of scientific men who assembled to do honour to Galileo's memory, and of the great institution with which, as it remembers with veneration and pride, he was so intimately associated.

On December 6 the Rector, Prof. C. J. Ferraris, received in one of the courts of the old University, adorned everywhere with portraits of the most illustrious professors, delegates from the Universities, the polytechnic schools, and Italian and foreign Academies, amounting to nearly a hundred, and amongst them many of those who shed most lustre on contemporary science. The University of Cambridge was represented by Prof. George Howard Darwin, F.R.S., who also represented the Royal Society as Mr. Norman Lockyer, its delegate, had been prevented from attending. The University of Oxford by Prof. E. J. Stone, the Royal College of Physicians, London, by Sir Joseph Fayrer, F.R.S., the Chemical Society and British Association by Prof. Ludwig Mond, F.R.S., the Harvard University, Cambridge, U.S.A., by Prof. William James, and the Princeton University by Prof. Allan Marquand; the University of Lund by Prof. R. A. V. Holmgren, the Astronomical Observatory of Paris by its Director, Prof. F. Tisserand, that of Berlin by Prof. W. Foerster, the Polytechnic Schools of Berlin, Karlsruhe, Monaco, Brunswick, Stuttgart, by Profs. Lampe, Keller, Sohncke, Blasing, Lemcke, the University of Göttingen by Prof. Voigt, that of Budapest by Prof. Lanczy, that of Dorpat by Prof. Schmourlo; that of Lausanne by its Rector, Prof. Favey, the Academy of Paris by Prof. Gariel, the Faculty of Letters at Grenoble by Prof. de Croyals; the General Council of the Faculty at Nancy by Prof. Molk, &c., &c. There were also delegates from the towns of Florence, Pisa, Venice, and representatives from the foremost Italian Universities, Academies, and Technical Schools.

The great academical celebration took place on December 7 in the large hall of the University, in the presence of the Hon. Ferdinando Martini, Minister of Public Instruction, who represented the King of Italy. The ceremony was begun with a discourse prepared for the occasion by the Rector Magnifico, and devoted principally to a cordial expression of thanks to the King and to the Minister who represented him; to the foreign and Italian delegates, and to the ladies of Padua, who had given the University a most beautiful banner, on which were various emblems indicating the history of the University, the genealogical tree of the Galileo family, and the ancient inscription above the door of the University—*Gymnasium omnium disciplinarum*.

Next came the commemoration of Galileo by Prof. Antonio Favaro, who has for nearly fifteen years devoted himself almost exclusively to the study of the life and works of Galileo, and to whom was confided by the Government the care of the national edition of the philosopher's works, under the auspices of the King of Italy. The orator kept his discourse within the limits marked out for him, speaking chiefly of Galileo at Padua. Constrained to leave the University of Pisa, Galileo had been welcomed in that of Padua, where he found the "natural home of his mind," a "theatre worthy of his talents." The conditions at Padua at that time were eminently favourable to Galileo's work, for the Venetian

Senate granted the lecturers the utmost liberty, and experimental methods, which could not be learned from books, had been practised at the University for more than a century Galileo had many opportunities for the development of his genius, both in the lecture-room and in the home, in the preparation of scientific publications, and in the workshops of scientific instrument-makers both in Padua and Venice To Venice he frequently went, attracted thither by the means it afforded him for study, by that grand arsenal which had already been sung by Dante, and which in his reputed Dialogues is spoken of by Galileo with admiration, but above all by the advantages he derived from scientific intercourse with eminent men who resided in the dominion The culminating point of the discourse was naturally reached when the orator had to deal with the invention of the telescope, and with the astronomical discoveries made by means of it, the immediate result of which was the recall of Galileo to Tuscany. This did not aid Galileo in his glorious career, or help to protect him from the attacks which were for a long time made on him by invidious adversaries Even some of his own servants changed at once to implacable and dangerous enemies, and at last he was involved in all the miseries which sprang from the memorable lawsuit. This led the orator to recall the fact that when the clouds assumed their most threatening aspect, the Venetian Republic, forgetting with real magnanimity whatever resentment it might have felt at Galileo's abandonment of his chair at Padua, offered to re-appoint him, and to print at Venice the work which had brought upon him so much trouble He said also that a pleasant memory of Padua must have passed through the mind of the prisoner of the Holy Office, when there came to him his only comfort, the message from the favourite of his childhood, the nun who in Padua had tenderly cared for him during the first ten years of his youth.

After Prof Favaro's oration discourses were delivered by the foreign delegates, Holmgren, Fayrer, Darwin, Tisserand, Lampe, Keller, Foerster, Sohncke, Blasing, Lemcke, Farey, Lanczy, Schmourlo, and by Italian delegates, Nardi-Dei, Mantovani-Orsetti, and Del Lungo Then followed the conferring of University honours, of which seven had been set apart by the Council for seven men of science, one for each nation, all distinguished for their devotion to the studies in which Galileo excelled, viz Schiaparelli, Helmholtz, Thomson, Newcomb, Tisserand, Bredichin, and Gylden The degree of philosophy and letters was given to the Minister Martini; of natural philosophy, and philosophy and letters, to the leading delegates The ceremony was closed by the inauguration of a commemorative tablet in the large hall

Of the other festivals connected with the celebration it would be out of place to speak here, and it will be better to add a list of the publications which have been issued on the occasion The oration read in the Great Hall by Prof Favaro has been published, with the addition of twenty-five facsimiles of documents containing the various decrees of the Senate concerning Galileo, the date of the early prelections given by him at regular intervals, several autographic records of Galileo, chosen in order to give a more exact idea of what are the most precious materials for his biography, the frontispieces of the various publications issued by Galileo, or relating to the time of his sojourn in Padua, the geometric and military compass, the writing presenting the telescope to the Doge, and the first observations of the satellites of Jupiter. A portrait of the great philosopher, from a painting which represents him at the age of forty, taken in 1604, is prefixed.

By favour of the University there have also been published two other works, one containing all the notices of the studies at Padua in 1592, the other proving which was the house inhabited by Galileo and the place in which he made his astronomical observations The ancient Academy of Padua, among whose founders Galileo is numbered, has issued a publication in which are collected several works dedicated to his memory, and the students of the University have sought to perpetuate the remembrance of this festival by the publication of a "unique number," bringing together all the documents relating to the sojourn of Galileo in Padua, collected from all quarters These publications will serve as suitable memorials of a great and most interesting celebration

ANTONIO FAVARO

SIR RICHARD OWEN

IT is with great regret that we record the death of Sir Richard Owen He died on Sunday, after a lingering illness, at Sheen Lodge, Richmond Park, in his eighty-ninth year In publishing his portrait in the series of "Scientific Worthies" (NATURE, vol. xxii p 577) we have already presented an estimate of his work and of his place in the history of science It is only necessary now, therefore, to recall some of the leading facts of his career

He was born at Lancaster on July 20, 1804, and received his early education at the grammar school of his native place Afterwards he matriculated at the University of Edinburgh as a medical student In 1825 he joined the medical school of St Bartholomew's Hospital, London, and in 1826 he took his diploma at the Royal College of Surgeons His professional studies having been completed, he began to practise in Serle Street, Lincoln's Inn Fields, but the bent of his mind was towards purely scientific investigation, and he soon had a good opportunity of exercising his powers Dr Abernethy, with whom he had acted at St Bartholomew's as a dissector, had recognized his ability, and, in accordance with the advice of this famous surgeon, he was invited in 1828 to undertake the task of cataloguing the Hunterian collection at the Royal College of Surgeons The invitation was accepted, and in 1830 the first catalogue of the invertebrate animals in spirits was published In the same year Owen read at the first meeting of the Zoological Society's committee of Science a valuable paper on the anatomy of the orang-utan, and afterwards he made many important contributions to the Society's Transactions and Proceedings He was also well known as a reader of papers before the Medical Society of St. Bartholomew's and the Medical and Chirurgical Society of London. In 1832 appeared his well-known essay on the Pearly Nautilus (*Nautilus Pompilius*), in which he gave most striking proof of his power of interpreting the facts of natural history in a thoroughly philosophical spirit

Before he was thirty years of age Owen had achieved so good a reputation that in 1834 he was appointed to the newly-established chair of comparative anatomy at St Bartholomew's Hospital Two years afterwards he succeeded Sir Charles Bell as professor of anatomy and physiology at the Royal College of Surgeons, and he was elected to the newly-established Hunterian professorship at the Hunterian Museum He also became conservator of the Hunterian Museum on the death of Mr Clift, whose daughter he had married He had gradually been withdrawing from the practice of his profession, and ended by devoting the whole of his time and energy to scientific work

His connection with the Royal College of Surgeons lasted for twenty years, and during this period he achieved results which placed him in the front rank of original investigators. In the article to which we have referred we have already indicated the nature and importance of these results, and need not go over the same ground again It must suffice to mention the completion, in five volumes, of his catalogue of the Hunterian

collection, his "Odontography", his Lectures on Comparative Anatomy and Physiology; his "Archetype and Homologies of the Vertebrate Skeleton", his memoirs on "The Nature of Limbs" and on "Parthenogenesis", his monograph of British fossil reptiles, and his papers on the fossil birds of New Zealand, and on some fossil mammals of Australia In 1856 he was appointed Superintendent of the Department of Natural History in the British Museum How splendidly he fulfilled the duties of this position all the world knows He fought steadily and earnestly to obtain proper accommodation for the magnificent collection placed under his charge, and to him, more than to any one, Great Britain owes the fact that this particular set of her scientific treasures is now so securely preserved and so finely displayed The practical duties of his office were not allowed to interrupt his scientific researches, and year after year he continued to give fresh evidence of the astonishing range of his knowledge and of his remarkable capacity for far-reaching and brilliant generalization Among the writings of this period are his Manual of Palæontology, and his memoirs on the classification and geographical distribution of mammals, on the British fossil reptiles of the Liassic formations, ichthyosaurs and plesiosaurs, on the British fossil cetacea of the Red Rag, on the British fossil reptiles of the Mesozoic formations, pterodactyls, and on the fossil reptiles of South Africa

In 1883 he resigned his official position, but he did not cease to interest himself in the studies in the prosecution of which he had displayed so commanding a genius In 1884 he issued in three volumes his great "History of British Fossil Reptiles," and until a comparatively recent date he submitted to the Royal Society from time to time papers embodying the more important results of his labours.

In the course of his long career Owen did much good service as a member of various Commissions, and it is scarcely necessary to say that honours of many different kinds were conferred upon him About these matters we have given all necessary information in our previous article Owen was very far from being content merely with the collection and classification of facts, he sought also to bring out the ideas in which his facts seemed to him to find their ultimate significance He was unable to adopt the theory of evolution as presented by Darwin, but his researches did much to prepare the way for the general and rapid acceptance of Darwin's hypothesis, since it was felt that there must be some strictly scientific explanation of the affinities by which he had shown vast groups of animal forms to be allied to one another Apart altogether from its speculative aspects, his work is universally acknowledged to be of high and enduring value, and there can be no doubt that he will rank among the strongest and most impressive figures in the intellectual history of the nineteenth century

He desired that his body should be buried beside that of his wife in Ham Churchyard, and his wish is, of course, to be complied with At the funeral, which will take place to-morrow (Friday), there will be representatives of all the learned societies with which he was connected

NOTES.

THE following memorial, numerously signed, has been presented by Sir Henry Roscoe to the Right Hon the Earl Cowper, Chairman of the Royal Commission on the Gresham University:—The undersigned desire hereby respectfully to record their strong opinion that the foundation of a Teaching University for London, without due provision being made for higher Education and original Research, would be unworthy of the Metropolis, and would entail the neglect of an admirable opportunity for promoting the advancement of Science and Learning The signatures cannot fail to command attention The following learned Societies are represented by their Presidents.—The Royal Society, the British Association for the Advancement of Science, the Royal Dublin Society, the Royal Society of Edinburgh, the Iron and Steel Institute, the Physical Society, the Institution of Electrical Engineers, the Institute of Mechanical Engineers, the Chemical Society, the Royal Horticultural Society, the Pharmaceutical Society of Great Britain, and the Institute of Chemistry of Great Britain and Ireland Eton College, Harrow School, Rugby School, and St Paul's School are represented by their head-masters There are also representatives of the University of Oxford, Cambridge, Edinburgh, Glasgow, Aberdeen, and St. Andrews, the Victoria University, the British (Natural History) Museum, the Royal College of Science, London, University College, London, Mason College, Birmingham, Durham College of Science, Firth College, Sheffield, University College, Dundee, University College, Bristol, City and Guilds of London Central Institution the Royal College of Science, Dublin, and the Pharmaceutical Society of Great Britain A special group of signatures consists of the names of a number of Fellows of the Royal Society

SIR JOSEPH LISTER, Sir Henry Roscoe, and Prof. Ray Lankester, will represent the Royal Society at the Pasteur celebration in Paris on the 27th inst Captain Abney has been invited to represent the Society at the 150th anniversary of the American Philosophical Society in May 1893

WE are glad to see that a movement has been started for the purpose of securing that due honour shall be done to the memory of Jean Servais Stas, one of the most illustrious of modern chemists It is proposed that a new edition of his writings shall be issued, his memoirs, notes, and reports being grouped in their proper order, and that a commemorative monument shall also be erected An influential committee, representing science in all parts of the world, has been appointed to take the necessary steps Subscriptions will be received by M. L Errera, 1, Place Stéphanie, Brussels

THE Committee of the International Electrical Exhibition to be held at Milan in 1894 proposes, according to *La Lumière Electrique*, to offer a prize for the most important invention or discovery in the province of electricity, especially in connection with the transmission of energy to a great distance, and its distribution and transformation for industrial uses

SUCCESSFUL experiments have been made in France relative to the introduction of telephones for use in warfare The telephonists are organized in sets of two men, each set being provided with equipment for a mile line The very simple receiving and transmitting apparatus are attached to the military cap, and the wire is on reels in a sort of breast-plate, the whole being so light that a man's ordinary equipment weighs less than six pounds

THE tunnel at Niagara Falls is finished, and the power plant will be in operation by next March It is expected that a current of 45,000 electric horse-power will be transmitted from there to Buffalo, and 30,000 to other points

M. MAURICE MALLET, in *L'Aéronaute*, describes what he claims to be the longest balloon ascent on record. His balloon, "Les Inventions Nouvelles," started from the gasworks of La Villette, Paris, on October 23, and the voyage terminated at Walhen, in Central Germany, at 6 a.m. on the 25th, after a total journey of 36 hours 10 minutes above ground The flight was interrupted several times by the snow which fell in the higher regions of the atmosphere When lower strata were reached, the snow melted, and the balloon regained its ascending power. During one of these descents it was stopped and examined by

a Prussian *gendarme*, who had followed it at a gallop for some distance. The route passed over part of Belgium, the Taunus, and the Odenwald, and the towns of Metz and Frankfurt were recognized in passing

The "Annals of the Harvard College Observatory" contain a discussion by H H Clayton of the cloud observations made at Mr A L Rotch's observatory at Blue Hill, Massachusetts One of the most noticeable facts brought out by the measurements of cloud heights and velocities, which have been conducted with great care, is the difference in height between the same clouds in summer and winter, the clouds, with few exceptions, being lowest in winter The bases of the cumulo nimbus clouds, however, are generally lower in summer, while, at the same time, their tops are higher than in winter The heights of the different clouds were found to maintain an almost constant ratio to each other The mean velocities recorded showed that the entire atmosphere moves twice as fast in winter as in summer The mean velocity of the highest clouds in winter was about 100 miles an hour, the extreme velocity amounted to 230 miles an hour, from which it appears that the upper currents are much more rapid over America than over Europe, which possibly explains the greater velocity of the storms in America As regards the directions of cloud movement, the tables show that from the highest clouds to the earth's surface, the prevailing wind is west, above 4000 metres more than 90 per cent of the observations show the clouds from some point between south west and north-west inclusive In the cirrus and the cumulus regions, and near the earth's surface, the prevailing direction is from a little north of west, but in the intermediate levels, from a little south of west, the excess of the southerly component in these regions being possibly due to the influence of cyclones

The weather during the past week has been generally very dull, and scarcely any rain has fallen over the southern parts of the kingdom Between Friday and Monday there were several depressions to the northward of our islands, passing in an easterly direction, which caused very severe gales and high seas on the coasts of Scotland, the difference on pressure on Sunday between the north and south of our islands being more than an inch During the first part of the period the temperature was unusually high for the season, the maxima exceeding 55° in some parts, and the night minima were occasionally higher than the average daily maxima for the month, subsequently, however, a decided fall occurred, with fog and mist in most parts of England, while in Scotland hail and sleet showers were experienced The *Weekly Weather Report* of the 17th instant shows that for that period the temperature was from 2° to 4° above the mean Rainfall exceeded the mean in the north of Scotland only, and just equalled it in the north of Ireland, in all other parts there was a deficiency Bright sunshine was much less prevalent than during the preceding week, although in most parts of England the amount exceeded the average

Prof Cole writes from Dublin that the afterglow in the west and zenith on Saturday, December 17, was of a superbly brilliant character Mr. R Langton Cole observed that in London on December 15 the whole sky was covered by the glow, which was deeper all round towards the horizon

An interesting lecture on "Water and Water Supply" was delivered last week at the London Institution, by Major L. Flower, of the Sanitary Institute. As an instance of the important part which water played in the economy of nature, he mentioned that if a man weighing 140 lbs were placed under a hydraulic press and squeezed flat, the result would be 105 lbs. of water, and only 35 lbs. of dry residue, which was a fact for conceited people to reflect upon. Major Flower gave some interesting facts about the rainfall of England. It is, of course, highest in mountainous districts, the maximum fall being found in Cumberland, where the record for six years shows an annual rainfall of 165 in The lowest in England is between Biggleswade and Bedford, where it reaches only 20 in London and the east coast average about 25 in Speaking of drinking water, Major Flower said the best way to get it was to bottle it at the fountain head and have it delivered in bottles, which had been done already and might be done to a greater extent in the future

Mr W F Howlett writes to us from Pahiatua, New Zealand —"Can you inform me what is now sold in England as gum arabic? I used to be able to buy a soluble gum, what I get now is the same in appearance, but it will not dissolve It swells up, truly, but will not form a homogeneous filterable solution. It would be a great boon to small buyers if such things were sold under their proper names Am I right in supposing that since the Soudan trouble gum arabic has disappeared from commerce?"

A very interesting report on artesian boring, by Mr J W Boultbee, is included in the volume containing the annual report of the Department of Mines and Agriculture, New South Wales, for the year 1891 Mr Boultbee shows that, as a rule, artesian waters are suitable for irrigation purposes, only those heavily charged with salt or alkaline matters being unsuitable, and he can see no reason why such irrigation should not be an element of immense value, deserving the utmost consideration in connection with the development of that north western portion of the colony, where the fertility and recuperative powers of the soil are so wonderfully illustrated by the growth of feed after rainfall at the proper season The average quantity of water required for the irrigation of grain crops, based upon the experience of other countries, may be roughly estimated at 72,600 cubic feet, or 543,485 gallons per acre One inch of rain would equal 3630 cubic feet, or 22,622 gallons per acre A rainfall of 20 inches would therefore yield 72,600 cubic feet, or 543,485 gallons per acre 640 acres would consequently require 46,464,000 cubic feet, or 347,830,400 gallons upon them as an equivalent to 20 inches of rain When it is considered that the flow per diem from the Native Dog Artesian Bore, 45 miles from Bourke, is approximately 2,000,000 gallons per diem, or 730,000,000 gallons per year, it will be seen that upon the foregoing basis a supply of water equal to a rainfall of 40 inches per annum, per 640 acres is available, or that an area of considerably over 1280 acres can be supplied with water equalling a rainfall of 20 inches per annum.

The Cambridge Local Lectures Syndicate have just issued an announcement of their next Summer Meeting of University Extension students, to be held at Cambridge in August, 1893 The programme is a large and varied one, and a number of well-known lecturers have already promised their services Among the scientific lecturers we notice the names of Sir Robert Ball, Sir H. E Roscoe, Mr Pattison Muir, and several of the best known of the Cambridge Extension lecturers Cambridge has always laid great stress on the importance of providing, as far as possible, practical work in science as well as theoretical teaching It has seldom been found possible to arrange much practical work in connection with the lectures given in the provinces, chiefly on account of the difficulty of finding laboratory accommodation, But students who can spare a fortnight—or, better still, a month—have now the opportunity of coming to Cambridge and seeing, at any rate, something of the resources of the University laboratories Even two or three weeks' work in a well-equipped laboratory may easily be a revelation to a student who has hitherto learnt his (or her) science from books or lectures. The laboratory work has always formed an important and highly appreciated part of the

Cambridge Summer Meetings Next year no less than five practical courses are promised, viz. in physics, chemistry, botany, physiology, and palæontology, thus providing for a considerable variety of taste, and for the accommodation in the laboratories of a fairly large number of scientific students Another feature in the programme is an entire novelty It is proposed to give a series of short courses of lectures on the growth of various sciences—astronomy, physics, chemistry, and geology—to illustrate from different points of view the methods by which discoveries are actually made, and science makes progress These will be accompanied by a short theoretical course on scientific method The sciences selected only cover a small portion of the whole field, and some aspects of scientific method—such as classification—will obviously scarcely be represented The organic sciences generally are left out, and may possibly form the groundwork of a similar scheme on some future occasion The idea of illustrating scientific method by the history of science is a familiar one, and is the basis, for example, of Whewell's great books on "The Philosophy and the History of the Inductive Sciences" Few men, however, possess the encyclopædic knowledge of science which Whewell had, and the progress of science since his day would make such a task as he undertook well nigh impossible for a more modern writer The Cambridge Syndicate do not attempt to find a Whewell, but hand over the history of each science to competent specialists, and hope to give real unity to the whole by the lectures on method, in which the lessons taught by the history of the various sciences will be brought into a focus, and made to lead up to general principles. The experiment is certainly an interesting one, and we shall watch with some interest to see how it succeeds The programme includes also lectures on history, literature, art, and other subjects But we have dwelt only on the science as being of special interest to our readers.

IN the Herz oscillator, as used hitherto, the spark discharge of a Rhumkorff has been produced in air between two balls MM Sarasin and de la Rive lately thought (*Arch. de Sciences*) to place the balls in an insulating liquid, and they find that this gives a more intense effect in the resonator Olive oil does best, oil of turpentine, liquid paraffin, and petroleum were also tried Placed near the oscillator the resonator gives quite a bright spark, and at about 30 ft distance, with a resonator of large diameter, the spark is strong enough to be visible a good way off

ATTEMPTS are being made to create a silk-producing industry in the district of Nicolaieff, in South Russia and, according to the British Vice-Consul at Nicolaieff, the result is not unlikely to be satisfactory He says that the mulberry tree, for the growth of which the soil and climate are well adapted, flourishes wherever it is planted, and that with very little trouble or expense every little plot of ground, now yielding nothing more than a crop of weeds, might in a short time be transformed into a remunerative feeding-ground for the silkworm The matter has been taken in hand by a society, and every encouragement is given to the peasants and poorer classes to take advantage of the opportunities provided for them If seriously followed up, the scheme may, the Vice-Consul thinks, prove a source of revenue to many a poor family, and eventually be the means of establishing a large and flourishing industry

AT a recent meeting of the Trinidad Field Naturalists' Club there was some discussion as to the question whether the bite of the tarantula (Mygale) spider is poisonous. Mr. C W Meaden, writing to the Club's journal on the subject, describes an incident which came under his own observation. Early in the present year he had a gang clearing some land after burning, and on visiting them one afternoon he saw a black tarantula dart from a heap of bush and deliberately bite one of the prisoners on the heel and then scamper away, which it did with safety to itself, although chase was made after it The spider seemed to be in an angry mood at being disturbed in a favourite haunt for food and shelter The bite drew blood, about two or three drops A Trinidad labourer's foot is thick enough almost to resist an auger, yet the spider managed to penetrate, so it may safely be asserted it was in earnest. Immediately the bite was given a shout went up, "The man is bitten by a big black spider—a tarantula!" This made the bitten one almost frantic with fright, and he cried out piteously, "Me God, me go die in gaol, me God," &c Mr Meaden took him to the infirmary, some 300 yards distant, and the sufferer carried his heel in his hand, *i e* hopped all the way. His foot was fomented with hot water, and spirits of ammonia were applied, with the addition of a little liquid ammonia, and he received a dose of ether mixture About two hours afterwards he ate his dinner heartily and slept well at night He complained of no pain in the morning, and went to work as usual There was no local swelling or inflammation, and but little pain at any time Fright was the only ill effect

SOME interesting results in application of cold have been recently recorded Thus M d'Arsonval has found that while with rising temperature, microbes die before soluble ferments, with lowered temperature the opposite occurs The invertine of beer yeast cooled to $-40°$C, does not lose its power, but it is destroyed as a ferment at $-100°$ On the other hand, the yeast itself cooled to $-100°$ is still active M Raoul Pictet has lately observed that at $-150°$ all chemical reaction is suppressed Thus, if sulphuric acid and potash are brought together at this temperature, they do not combine Litmus paper, introduced, keeps its colour. Curiously, it is possible to restore their energy to these inert substances, by passing an electric current, and the current passes readily whatever the substances, at $-150°$ all bodies are good conductors The disappearance of affinity at a low temperature can be utilized to get absolutely pure substances, and M Pictet has thus obtained alcohol, chloroform, ether, and glycerine

SOME good notes on the Shuswap people of British Columbia, read before the Royal Society of Canada by Dr George Dawson, F R S, are now printed in the Society's Transactions, and have also been issued separately In an interesting section on the superstitions of the Shuswaps he notes that they have a singular idea about certain small lizards A man who sees one of these creatures is supposed to be followed by it wherever he may go during the day, till at length, when he is asleep during the following night, it finds him, and entering his body, proceeds to eat out his heart, so that he quickly dies The late Mr Bennett, of Spallumsheen, told Dr Dawson in 1877 that the Indians employed by him in making a ditch for purposes of irrigation, on coming into camp in the evening, would jump several times over the fire in order to lead the possibly pursuing lizard to enter the fire and be destroyed in attempting to cross. He also noticed that they carefully tied up the legs of their trousers when retiring. If while at work during the day they saw one of these little lizards, which appeared to be abundant in that locality, it would be caught in a forked twig, the ends of which were then tied together with a wisp of grass and the butt end of the twig afterwards planted in the soil. Thus treated, the lizard soon died and become a natural mummy. If during the progress of the work any one found and carelessly tossed aside one of these lizards, the Indians would throw down their tools and search diligently until they found it, and secured it in the manner just described. Dr. Dawson thinks that this superstition must be widespread among the Indians, for it was afterwards related to him in identical form by a man of the Nicola River, who further pointed out a small lake, singularly

situated on the summit of a high ridge about a mile and a half south of the mountain named Za-kwās'-ki, as a noted resort—possibly the only place known to the man—of this peculiar animal He described it as being a few inches in length and nearly black Za-kwās'-ki, to which other stories attach, is south of Nicola River, at the source of the Nicoamen River

A COMMON impurity in many seeds which are used as food for live-stock is the seed of corn-cockle (*Agrostemma githargo*) Notably is this the case on the Continent, and especially in Hungary, where the refuse from the machines used in cleaning grain consists chiefly of cockle-seed, and is largely used in feeding swine It appears, as a rule, to have no ill effect upon these animals Upon other animals, however, it sometimes has serious and even fatal effects, especially upon calves and dogs According to Kobert (*Landw Centralblt Provinz Posen*, 19) it would appear that the seeds contain a glucoside—saponin $C_{32}H_{54}O_{18}$,—which acts as a poison either when eaten in the form of cockle-seed or when introduced into the blood Various animals are affected in different degrees, but dogs, cats, and birds soon die when fed upon the seed The poison decomposes the blood, dissolving the red corpuscles, and also destroys the sensitive albuminoid portion of the nerve elements Heating to 50° C. decomposes the saponin, and renders the seed harmless Since this glucoside is found to lie only just below the surface of the seed, Kobert suggests that the seed should be coarsely ground and the outer husk separated, to cook the meal would be a still safer precaution A good deal of cockle-seed comes into the port of Hull, chiefly, it is presumed, amongst grain which has not been screened From such seeds as linseed it is removed by screening before pressing, but it is too often found in the cake which results after the oil is expressed from the linseed A considerable quantity of corn cockle is handled in Hull, whatever its ultimate destination may be, and it sometimes occurs in feeding stuffs in far too large a percentage to be considered as an accidental impurity Its use in admixture (as impurity or otherwise) with other feeding stuffs is strongly to be deprecated so long as there is the slightest risk attending its consumption by any domestic animal Its detection is very easy, the peculiar rough husk of the seed being characteristic, the husk, after clearing with dilute sulphuric acid, and then with caustic soda, and examined under a low power of the microscope, will exhibit dark-red convoluted markings which distinguish it clearly from the husk of any other well-known seed

IT is a well known fact that sea anemones have a sense by which they recognize food. This has been studied recently by Herr Nagel at the Zoological Station in Naples, and he has endeavoured to localize it Among other experiments, a small piece of a sardine was brought carefully to the tentacles of one of these animals, the tentacle first touched, then others, seized the food and surrounded it, and the morsel was swallowed A similar ball of blotting-paper saturated with sea-water, brought near in the same way, was not seized If, however, the ball was soaked in the juice of fish, it was seized with the same energy as the piece of fish, but often liberated again after a time without being swallowed Blotting-paper saturated with sugar acted like the other, but more weakly. If saturated with quinine, it was refused, the tentacles drawing back On the outer surface of the body, as also in the part between the tentacles and the mouth, quinine had no effect, nor had coumarin, vanillin, or picric acid. When a piece of meat was placed in or near the mouth of a widely-open animal, no notice was taken of it, it was only seized when the tentacles were touched Thus the sense of taste seems to be in these alone Cutting the tentacles did not evidently give pain, but these organs appeared sensitive to heat and to touch, so that they appear to be the seat of three senses.

MR JOHN MURRAY has published a fourth edition of Dr W Fream's "Elements of Agriculture" The work was originally issued at the beginning of the present year, and two editions were sold out before the end of January The third edition has for some time been out of print The book has now been thoroughly revised, and enriched with a completely new set of illustrations

A NEW edition of Dr John Casey's "Sequel to the First Six Books of the Elements of Euclid" has been issued as a volume of the Dublin University Press Series The work has been edited by Prof P A E Dowling, by whom it has been carefully revised and considerably enlarged The editor has obtained much valuable aid from Prof Neuberg, of the University of Liège

MESSRS BLACKIE AND SON have issued a second edition, revised and enlarged, of Mr J McGregor-Robertson's "Elementary Text book of Physiology"

A FURTHER communication concerning the nature and properties of hydroxylamine, NH_2OH, is contributed to the *Recueil des travaux chimiques des Pays Bas* by M Lobry de Bruyn, whose isolation of the free base was described in our note of vol xlv p 20. It may be remembered that pure hydroxylamine was found to be a solid substance, crystallizing in colourless thin plates or needles, which are extremely deliquescent So powerful indeed is the affinity of hydroxylamine for water, that the crystals rapidly dissolve when exposed to the air, in the moisture attracted The crystals melt at a temperature of 33°, and the liquid boils at 58° under the reduced pressure of 22 millimetres If the liquid is heated under ordinary atmospheric pressure in contact with the air, it explodes with great violence when a temperature between 60° and 70° is attained, if the experiment is carried out in a vessel from which air is excluded, the liquid may be heated as far as 90° without accident, regular decomposition into gaseous products occurring at this temperature Explosion, however, usually follows at once if this temperature is much exceeded, and generally after a short time if the source of heat is removed as soon as the thermometer has reached 90°, inasmuch as the decomposition which is induced at this temperature is accompanied by evolution of heat. The crystals are without odour They react with considerable violence with the halogen elements, the reaction in the case of chlorine being accompanied by production of flame, the products do not appear to have been investigated as yet beyond ascertaining the presence among them of the halogen acids. Metallic sodium also vigorously attacks hydroxylamine, brilliant incandescence occurring Warm zinc dust reduces it to ammonia so rapidly, that if any considerable quantities are employed a violent explosion follows Highly oxidized compounds, such as potassium permanganate, chromates, bichromates, or chromic acid react with crystals of hydroxylamine, as may be expected, in a most energetic manner, brilliant flame being produced often accompanied by detonation Chlorates, perchlorates and bromates behave similarly in the presence of a drop of sulphuric acid Hydroxylamine liberates iodine from iodic anhydride, and rapidly reduces iodates to iodides. Dehydrated sulphate of copper inflames in contact with the crystals of the base, and powdered nitrate of silver is reduced to metallic silver Addition of trichloride or pentachloride of phosphorus to the crystals likewise brings about ignition Hydrogen peroxide oxidizes hydroxylamine to nitrous acid These reactions, selected from a large number which M. de Bruyn describes, amply demonstrate the remarkable chemical energy with which anhydrous hydroxylamine is endowed. It is interesting to learn that the melted substance is capable of dissolving a considerable volume of ammonia gas. Moreover, carbon dioxide and sulphuretted hydrogen are so soluble in melted hydroxylamine that

viscous liquids are produced which remain liquid even at $-10°$ As regards the preparation of the base, M de Bruyn has now succeeded in obtaining a hundred grams of the pure crystals from a little more than a kilogram of the hydrochloride, by the method described in our previous note above referred to

THE additions to the Zoological Society's Gardens during the past week include a red and yellow macaw (*Ara macao*) from Central America, presented by the Rev T N Talfourd Major, two gold pheasants (*Thaumalea picta* ♀ ♀) from China, an Alpine Chough (*Pyrrhocorax alpinus*), European, purchased

OUR ASTRONOMICAL COLUMN

COMET HOLMES (NOVEMBER 6, 1892) —The following ephemeris, taken from *Astronomische Nachrichten*, No 3131, gives the position for Comet Holmes for the ensuing week —

Berlin, Midnight

1892	R A. (app.). h m s	Decl (app) ° ′	Log r	Log Δ
Dec 23	0 55 44	+34 19 2		
24	56 37	16 0	0 4050	0 3049
25	57 31	12 9		
26	58 27	10 0		
27	0 59 24	7 2		
28	1 0 22	4 5	0 4073	0 3167
29	1 1 21	34 1 9		

M Deslandres, in *Comptes rendus* for December 12 (No 24), informs us that on November 21 he obtained a photograph of this comet between 10h 40m and 11h 20m Paris mean time, showing distinctly "un commencement de dédoublement" Owing to the bad weather no other negatives were taken until December 10, but although the time of exposure was an hour, the comet's impression was not obtained, thus confirming the present eye observations that its intensity is slowly decreasing

COMET BROOKS (NOVEMBER 20, 1892) —The following ephemeris of Comet Brooks is that obtained by Berberich, and varies a little from that given last week, as will be seen by comparing the values for December 22, with those given last week.—

Berlin, Midnight.

1892	R A. h m s.	Decl ° ′	Log Δ	Log r	Br
Dec 22	14 26 9	+42 50 2

SWIFT'S COMET —*Knowledge* for December 1 contains three most interesting photographs of Comet Swift, taken by Prof Barnard at the Lick Observatory on April 4, 6, and 7 respectively These photographs, which are obtained from the original negatives after an enlargement of 2¼ times, show what good photographic work can be done even with small instruments when exposures are somewhat lengthened In this case a 6-inch Willard lens of 31 inch focal length was strapped on to the tube of a 6½-inch equatorial, and the exposures given amounted to 60, 65, and 50 minutes The ordinary driving-clock, combined with a slight hand movement at the eye end, were all that was required to compensate for the diurnal and proper motion of the comet The star trails on the plates pointed out then the comet's proper motion Although these photographs were taken at such short intervals the changes recorded are most striking, the pictures bearing very little likeness to one another On this point Prof Barnard says "Had they been drawn by the most competent observer, most astronomers would leave their remarkable differences to the unskilful hand of the artist, for there is absolutely no resemblance among them." The photographs here referred to are from a series taken at Mount Hamilton, and in examining them he mentions that in the case of this comet he has been led to forcibly believe that in a comparatively short period there occurred a rotation of the tail "upon an axis through the nucleus."

ULTRA-VIOLET SPECTRUM IN PROMINENCES —In the current number of the *Memorie della Società Degli Spettroscopisti Italiani*, Prof. G. E Hale communicates a note on some photographs of the ultra-violet region in the spectra of solar prominences On October 15 at 3h 15m a photograph of the spectrum of a metallic prominence was obtained, which contained as many as 74 bright lines in the ultra violet between wave-lengths 3970 and 3630 The photograph, besides displaying all the lines previously recorded by Prof. Hale and M Deslandres, contained 32 additional lines which had not been previously known The following table shows their respective wave-lengths, which are to be regarded yet as only approximate.—

λ	λ	λ
3964	3863	3724 3
3956 9	3850 5	3716 9
3945 2	3813 5	3710·3
3938 1	3774	3699 5
3913 5	3767 1	3683
3965	3758	3681
3895 5	3757	3679 5
3893 8	3749 7	3674 2
3891	3741 7	3662 2
3878 8	3733 3	3647 8
		3632
		3630·8

Besides these lines the photograph shows traces of the lines λ 3807 2, 3802, 3764, 3763, 3758 2, 3709 5, 3707 8, 3676, 3643

EPHEMERIS FOR BODIES MOVING IN THE BIELA ORBIT — In *Astronomical Journal*, No 281, Dr Chandler communicates an ephemeris for the use of those wishing to search for bodies which may be moving in the orbit of Biela's comet The ephemeris is given for every eight days It is based on the orbit obtained by Michez, who calculated the principal perturbations up to 1866 In the present computations Dr Chandler has not taken into account any disturbance that may have been produced by the proximity of the planet Jupiter, or any perturbation that might have ensued from an approach to our earth The values are given up to the end of February, 1893

MADRAS MERIDIAN CIRCLE OBSERVATIONS —The Government of Madras has lately issued the results of observations of the fixed stars, made with the meridian circle during the years 1874–76 During this interval no change whatever was made either in the instrument or in the methods of reduction The volume gives the instrumental corrections for these years, the separate results of observations for each year, with the mean positions of the stars brought up to January 1 of each year, and corrections to the Nautical Almanac stars for the period in question

THE JUBA RIVER

AT the meeting of the Royal Geographical Society on Monday evening, Commander F G Dundas, R N, read a paper describing his ascent of the Juba river This was the first serious attempt to explore the river since Von der Decken's ill-fated expedition in the *Guelph* in August, 1865 The stern-wheel steamer *Kenia*, belonging to the Imperial British East Africa Company, under the command of Captain Dundas, crossed the bar of the Juba on April 25, 1892, an operation of much danger, as the vessel was exposed broadside on to heavy rollers, the depth at high water is only one fathom, and the water swarms with sharks and crocodiles The coast Somalis lined the bank with hostile movements as soon as they saw that the vessel was to go up the river, and detained the expedition for a fortnight, until a message was sent to the head chief, the Sultan of the Ogaden Somalis It was July 3 before amicable arrangements could be made, and the expedition fairly started. The Somalis met with everywhere were very strict Mohammedans, and secluded their women, but a number of Galla slave-girls were seen amongst them There were few villages, Hajowan and Hajaualla opposite each other near the mouth being the only large ones until Munsur, 360 miles, and Bardera, 387 miles from the sea, were reached. The lower reaches of the river were very winding On one occasion Captain Dundas observed a stream flowing parallel to the river he was on, and going across to see it recognized the landmarks as those

he had passed three hours before The Waboni tribe, who live by hunting, and use the bow and arrow, occupied the thick woods of the lower river Above them the curves became more gentle, and the Gusha district was reached, where the people cultivated the land, which was cleared by burning, and for a hundred miles the *Kenia's* furnaces were fired with the dead trees which had been killed, but left unburnt by the fire Cotton is cultivated as well as food plants, and there is a primitive system of weaving Above Bilo, and about 100 miles from the sea, a branch was found to run off from the main river to the south west through very dense forests This is probably the Sheri, which reaches the sea midway between Lamu and Kismayu, the land between this and the Juba mouth being probably of deltaic origin This branch was explored in a boat for twenty miles The dense forests formed a broad belt on both sides on the river, and after steaming for five days through uninhabited woods the *Kenia* suddenly emerged into open country on August 2 The people were of very mixed race, friendly and well supplied with all sorts of food Hills began to appear, and the river grew shallower, until on August 10 the steamer moored to the bank opposite Bardera Here the Sultan forbad a landing, and the people, who numbered about 1200, were hostile, but ultimately peace was arranged, and one of the subordinate sheiks accompanied the *Kenia* to the rapids, where the river sweeps between steep rocky hills 300 to 400 feet high There are three channels in the rapids, but at the time of the visit none was navigable, and the natives reported a waterfall over a ledge of rock about four hours' march further up, in latitude 2°34' N The wreck of the *Guelph* was visited and examined, but the rapid falling of the water made it necessary to hasten back to the sea The climate throughout was found agreeable, and there were few mosquitoes The river does not overflow, so there are no malarial swamps along the banks

BREATH FIGURES[1]

FIFTY years back Prof Karsten, of Berlin, placed a coin upon glass, and by electrifying it made a latent impression, which revealed itself when breathed upon About the same time Mr W R (now Sir W R) Grove made similar impressions with simple paper devices, and fixed them so as to be always visible A discussion of Karsten's results occurs in several places, but I have not been able to find details of his method of performing the experiment During my attempts to repeat it some effects have appeared which seem to be new and worthy of record

After many trials I found the following method the most successful --A glass plate, six inches square, is put on the table for insulation in the middle lies a coin with a strip of tinfoil going from it to the edge of the glass · on this coin lies the glass to be impressed, four or five inches square, and above it a second coin It is essential to polish the glass scrupulously clean and dry with a leather the coins may be used just as they usually are, or chemically cleansed, it makes no difference The tinfoil and the upper coin are connected to the poles of a Wimshurst machine which gives three or four inch sparks The handle is turned for two minutes, during which one-inch sparks must be kept passing at the poles of the machine On taking up the glass one can detect no change with the eye or the microscope, but when either side is breathed upon, a clear frosted picture appears of that side of the coin which had faced it even a sculptor's mark beneath the head may be read For convenience those parts where the breath seems to adhere will be called white, the other parts black In this experiment the more projecting parts of the coin have a black counterpart, but there is a fine gradation of shade to correspond with the depth of cutting in the device; the soft undulations of the head and neck are delicately reproduced

The microscope shows that moisture is really deposited over the whole surface, the size of the minute water granulation increasing as the point of the picture is darker in shade

There seems to be no change produced by the use of coins of different metals.

If sparking is allowed across the glass instead of at the poles of the machine, traces of metal are sometimes deposited beyond the disk of the coin, but not within it

Around the disk is a black ring quarter inch broad. sometimes the milling of the coin causes radial lines across this halo

If carefully protected there appears to be no limit to the permanence of the figures, but commonly they are gradually obscured by the dust gathered up after being often breathed upon some of the early ones, done more than two years back, are still clear and well defined in the detail

It is possible to efface them with some difficulty by rubbing with a leather whilst the glass is moist They are best preserved by laying several together when dry and wrapping them in paper they are not blurred by this contact

It is a curious fact that certain developments take place after a lapse of some weeks or months The dark ring around the disk gradually changes into a series of three or four, black and white alternately, other instances of such a change will be noted below

Let it be noticed that in coin pictures the object is near to, but not in contact with, the glass for in the best specimens the rim of the coin keeps the inner part clear of the surface

Obviously a small condenser is made by the coins it is not essential, at the same time images made by a single coin, put to a single pole, are inferior

The plan which gives the surest and most beautiful results is to place five or six coins, lying in contact side by side in a cross or star, on either side of the glass it is not necessary that each coin should exactly face one on the other side

There has not appeared any distinction between the figures made by positive and negative electricity

When several coins are placed side by side, touching one another, there appear in the spaces between them, which are mostly black, well defined white lines, common tangents to the circular edges of the coins If these are of equal size the lines are straight, otherwise they are curved, concave towards a smaller coin They seem to be traces in that plane of the loci of intersection of equipotential surfaces

Similar effects are obtained when coins and glasses are piled up alternately, and the outer coins are put to the poles of the machine With six glasses and seven coins perfect images have been formed on both sides of each glass. With eight glasses the figures were imperfect, but there is little doubt this could be improved by continued trials as to the amount of electricity applied

If several glasses are superposed and coins are applied to the outer surfaces, there are only the two images at the outside After the electrification there is a strong cohesion between the plates.

It requires some practice to manage the electrification so as to produce the best results There are two forms of failure which present interesting features Sometimes a picture comes out with the outlines dotted instead of being continuous At other times, if the electrification is carried too far, the impression comes out wholly black, but on rubbing the glass when dry with a leather the excess is somehow removed Naturally it is difficult to rub down exactly to the right point, but I have succeeded on several occasions in developing from a blank all the fine detail of elaborate coins.

Here, again, we have another instance of the development by lapse of time, for an over-excited piece of glass usually gives a clear picture after an interval of a day or two

Impressions from stereotype plates have been taken of which the greater part is legible the distinctness usually improves after a few days. In default of a second plate, a piece of tin-foil about the same size should be put on the opposite side of the glass

Sheet and plate glass of various thicknesses have been used without any noticeable change either in the treatment or the results.

I have put an impressed glass on a photographic plate in the dark, but did not get any result on developing my imperfect skill in photographic matters leaves this experiment inconclusive

Probably all polished surfaces may be similarly affected a plate of quartz gives the most perfect images, which retain their freshness longer than those on glass

Mica and gelatine give poorer results · It is not possible to polish the surface to the necessary point without scratching it

On metal surfaces fairly good impressions can be produced if, as Karsten advises, oiled paper is put between the coin and the surface.

In the order of original discovery the figures noticed by Peter Riess should come first. He discusses a breath-track made on

[1] Paper read by Mr. W. B Croft before the Physical Society of London on June 24, 1892.

glass by a feeble electrical discharge, as well as two permanent marks, noticed by Ettrick, which betray a disintegration of the surface.

I have found that when a stronger discharge is employed more complex phenomena of a similar kind are produced. A six inch Wimshurst machine is arranged with extra condensers, as if to pierce a piece of glass. If this is about four inches square the spark will generally go round it. For a day, more or less, there is only a bleared watery track, $\frac{1}{10}$ inch wide, when the glass is breathed upon, but after this time others develop themselves within the first, a fine central black line with two white and two black on either side, the total breadth being the original $\frac{1}{10}$ inch. These breath-lines do not precisely coincide in position with the permanent scars, but the central one is almost the same as a permanent mark, which the microscope shows to be the surface of glass fractured into small squares of considerable regularity; on either side is a grey-blue line always visible, which Riess ascribes to the separation of the potash. After several months I found two blue lines on either side, which I believe were not visible at first. Of course these blue lines may be seen on most Leyden jars, where they have discharged themselves across the glass.

In 1842 Moser, of Konigsberg, produced figures on polished surfaces by placing bodies with unequal surfaces near to them; the action was ascribed to the power of light, and his results were compared with those of Daguerre. Moser says, "We cannot therefore doubt that light acts uniformly on all bodies, and that, moreover, all bodies will depict themselves on others, and it only depends on extraneous circumstances whether or not the images become visible." In general, the multitude of images would make confusion, it can only be freshly polished surfaces that are free to reveal single definite impressions. However great Moser's assumption may be, there are many achievements of modern photography that would be as surprising if they were not so familiar. I have not the means of knowing the precise form of Moser's methods. In the experiments which follow there is usually contact and light pressure, and if they are not wholly analogous, they may for that cause help to generalize the idea. In none of these is electricity applied.

A piece of mica is freshly split, and a coin lightly pressed for thirty seconds on the new surface: a breath image of the coin is left behind. At the same time it may be noticed that the breath causes abundant iridescence over the surface, whilst it is in a fresh state. It is not clear how the electricity of cleavage can have an active agency in the result.

It is familiar to most people that a coin resting for a while on glass will give an outline of the disk, and sometimes faint traces of the inner detail when breathed upon.

An examination-paper, printed on one side, is put between two plates of glass and left for ten hours, either in the dark or the daylight: a small weight will keep the paper in continuous contact, but this is not necessary if thick glass is used. A perfect breath impression of the print is made, not only on the glass which lay against the print, but also on that which faced the blank side of the paper. Of course the latter reads directly, and the former inversely; the print was about one year old, and presumably dry.

More often both impressions are white, sometimes one or other or both are black. At other times the same one may be part white and part black, and they even change while being examined.

During a sharp frost with east winds early in March, 1890, these impressions of all kinds were easy to produce, so as to be quite perfect to the last comma; but in general they are difficult, more especially those from the blank side.

At the best period those from the blank side of the paper were white and very strong; also there were white spots and blotches revealed by the breath. They seemed to correspond with slight variations in the structure of the paper, and suggest an idea that the thickness of the ink or paper makes a minute mechanical indentation on the molecules: the state of these is probably tender and sensitive under certain atmospheric conditions, as happens with steel in times of frost.

The following experiments easily succeed at any time:—Stars and crosses of paper are placed for a few hours beneath a plate of glass: clear white breath-figures of the device will appear. A piece of paper is folded several times each way to form small squares, then spread out and placed under glass: the raised lines of the folds produce white breath-traces, and a letter weight that was above leaves a latent mark of its circular rim.

Some writing is made on paper with ordinary ink and well dried: it will leave a very lasting white breath-image after a few hours' contact. If, with an ivory point, the writing is traced with slight pressure on glass, a black breath image is made at once. Of course this reads directly, and the white one inversely. It is convenient to look through the glass from the other side for inverse impressions, so as to make them read direct.

Plates of glass lie for a few hours on a table-cover worked with sunflowers in silk: they acquire strong white figures from the silk.

In most cases I have warmed the glass, primarily for the sake of cleansing it from moisture, but I have often gone to a heat beyond what this needs, and think that the sensitiveness has been increased thereby.

It is not easy to imagine what leads to the distinction between black and white, different substances act variously in this respect. I have placed various threads for a few hours under a piece of glass, which lay on them with light pressure: wool gives black, silk white, cotton black, copper white. A twist of tinsel and wool gives a line dotted white and black; after a time these traces show signs of developing into multiple lines as in the spark figures.

Two cases have been reported to me where blinds with embossed letters have left a latent image on the window near which they lay; it was revealed in misty weather, and had not been removed by washing. I have not had a chance to see these for myself, but both my informants were accustomed to scientific observation.

A glass which has lain above a picture for some years, but is kept from contact by the mount, will often show on its inner side an outline of the picture, always visible without breath. It seems to be a dust figure easily removed: possibly heat and light have loosened fine paint particles, and these have been drawn up to the glass by the electricity made in rubbing the outer side to clean it. The picture must have been well framed and sealed from external influences; most commonly dust and damp get in and obscure such a delicate effect.

I am not able to suggest simple causes for these varied effects. I am not inclined to think, except in the case of water colours, which is hardly part of the enquiry, that there is a definite material deposit or chemical change; one cannot suppose that imperceptible traces of grease, ineradicable as they may be, would produce complete and delicate outlines. The cleaning off of impressions may at first seem to indicate a deposit, but this renewal of the surface might rather be like smoothing out an indented tin-foil surface: such a view might explain the case where a blank over-electrified disk is developed into fine detail. The electrified figures seem to point to a bombardment, which produces a molecular change, the intensity of electricity bringing about quickly what may also be done by slow persistent action of mechanical pressure. At present it seems as if most of the phenomena cannot be drawn out from the unknown region of molecular agency.

While experimenting I was not within reach of references to former researches, but I have since done my best to find them out, and to indicate all I have learnt in the body of my paper.

SCIENTIFIC SERIALS

American Journal of Science, December.—An experimental comparison of formulæ for total radiation between 15° C. and 110° C., by W. de Conte Stevens. The formulæ given by Dulong and Petit, by Rosetti, Stefan, and Weber, were tested for a comparatively small range of differences by a determination of the heat radiated from an iron disc at a distance of about 30 cm. from a thermopile. The results tended to show that H. F. Weber's formula (*Sitzungsber.*, Berlin, 1888) agrees most closely with experiment. Stefan's formula, according to which the heat emitted in unit of time is proportional to the fourth power of the absolute temperature, is also fairly accurate,

but Dulong and Petit's values are too high, and Rosetti's too low.—Notes on silver, by M. Carey Lea.—Notes on silver chlorides, by the same. Fused silver chloride poured into petroleum and placed in the sunlight without removing it from the liquid, is instantly darkened. From this it appears that the presence of oxygen or moisture is not essential to the darkening of silver chloride in light. The chlorine may be taken up by some other substance.—A remarkable fauna at the base of the Burlington Limestone in north eastern Missouri, by Charles Rollin Keyes.—Glacial pot-holes in California, by H. W. Turner.—The lavas of Mount Ingalls, California, by H. W. Turner.—A method for the quantitative separation of barium from strontium by the action of amyl alcohol on the bromides, by Philip E. Browning. The solubility of barium bromide is about 0.0013 grm. on the oxide in 10 cc. of amyl alcohol, while that of strontium bromide is 0.2 grm. To obtain the bromides, the precipitated and thoroughly washed carbonates of Ba and Sr are treated with hydrobromic acid obtained by the action of dilute sulphuric acid on potassium bromide.—Note on the method for the quantitative separation of strontium from calcium by the action of amyl alcohol on the nitrates, by P. E. Browning. Recent work on this method has shown that the total correction amounts to 0.0006 grm. on the strontium oxide, and 0.0010 on the calcium as sulphate.—Study of the formation of the alloys of tin and iron, with descriptions of some new alloys, by W. A series of important investigations on discharges between electrodes and in tubes without electrodes.—Expansion of water with the temperature, by K. Scheel.—A method for determining the density of saturated vapours and the expansion of liquids at higher temperatures, by B. Galitzine. This method has the advantage of extreme simplicity combined with accuracy. A small glass tube, about 5 cm. long and a few mm. thick, is closed at one end and drawn out into a capillary at the other. After determining the weight and internal volume of the tube, a small quantity of the substance to be investigated is introduced into it in the liquid state. This is made to boil, and then the tube is sealed by fusing. On raising the temperature, the surface of separation between the liquid and its vapour is displaced, until at a certain temperature all the liquid is converted into saturated vapour. The tube is then cooled until the vapour reappears, when the temperature is again taken. This can be repeated several times, thus giving an accurate value for the density of saturated vapour at a certain temperature. The same process can be used to determine the expansion of the liquid. As the temperature rises, the volume of the liquid will in general increase up to a certain point, when the vaporization becomes more pronounced. This maximum, which can be observed more accurately by drawing out the tube near that point, gives a value for the expansion. For the density at that point is a function of the density at 0° C. and the temperature, and the pressure is that of the saturated vapour at the same temperature. Thus it is only necessary to find the volumes of the liquid and the vapour, and the density of the latter from the previous experiment.—On radiant energy, by B. Galitzine.—Note on the electricity of waterfalls, by J. Elster and H. Geitel.—Apparatus for demonstrating the Wheatstone bridge arrangement, by A. SOCIETIES AND ACADEMIES

LONDON.

Royal Society, December 15.—On some new reptiles from the Elgin Sandstone, by E. T. Newton, communicated by Sir Archibald Geikie, F.R.S.

During the last few years a number of reptilian remains have been obtained from the Elgin Sandstone at Cuttie's Hillock, near Elgin, which are now in the possession of the Elgin Museum and of the Geological Survey. These specimens represent at least eight distinct skeletons, seven of which undoubtedly belong to the Dicynodontia, and one is a singular horned reptile, new to science. All the remains yet found in this quarry are in the condition of hollow moulds, the bones themselves having entirely disappeared. In order, therefore, to render the specimens available for study, it was necessary, in the first place, so to display and preserve these cavities that casts might be taken which would reproduce the form of the original bones. Gutta-percha was found to be the most suitable material for taking these impressions; and in some instances, especially in the case of the skulls, the casts had to be made in several parts and afterwards joined together.

The first specimen described is named *Gordonia Traquairi*; it is the one noticed by Dr. Traquair in 1885, and referred to the Dicynodontia; besides the skull, it includes fragmentary portions of other parts of the skeleton, and is contained in a block of sandstone which has been split open so as to divide the skull almost vertically and longitudinally. The two halves have been so developed that casts made from them exhibit the left side and upper surface, as well as the main parts of the palate and lower jaw. In general appearance this skull resembles those of *Dicynodon* and *Oudenodon*. The nasal openings are double and directed laterally; the orbits are large and look somewhat forwards and upwards. The supra-temporal fossa is large, and bounded above by the prominent parieto squamosal crest, and below by the wide supra temporal bar, which extends downwards posteriorly to form the long pedicle for the articulation of the lower jaw. There is no lower temporal bar. The maxilla is directed downwards and forwards to end in a small tusk. Seen from above, the skull is narrow in the inter-orbital and nasal regions, but wide posteriorly across the temporal bars, although the brain-case itself is very narrow. There is a large pineal fossa in the middle of a spindle shaped area, which area is formed by a pair of parietals posteriorly and a single intercalary bone anteriorly.

The palate is continuous with the base of the skull; the pterygoids on each side send off a distinct process to the quadrate region. Towards the front the mediam part of the united pterygoids arches upwards, and the outer sides descend, forming a deep groove; from the evidence of other specimens it is clear that the palatines, extending inwards, converted this groove into a tube, and thus formed the posterior nares. The ramus of the lower jaw is deep, with a large lateral vacuity, and the two rami are completely united at the symphysis. The back of this skull is not seen, but two other specimens, referable to this same genus, show that the occiput had two post temporal fossæ on each side.

This specimen is distinguished from *Dicynodon* by the presence of two post temporal fossæ on each side of the occiput, by the small size of the maxillary tusk; and probably by the elongated spindle-shaped area enclosing the pineal fossa, and also by the slight ossification of the vertebral centra.

A second and much smaller specimen, provisionally referred to *G. Traquairi*, has, besides the skull, a fore-limb well preserved. The humerus of this shows the usual Anomodont expansion of its extremities; its large deltoid crest is angular, and set obliquely to the distal end.

Three other species are referred to the same genus, namely:—

Gordonia Huxleyana, which is distinguished from *G. Traquairi* by its proportionately wider and more depressed skull, and by the absence of the concavity between the orbits which is present in the latter species. The humerus has the distal extremity oblique to the deltoid crest, which was probably rounded and not angular.

G. Duffiana has the skull even wider than in *G. Huxleyana*, and the portion of a humerus found with this skeleton has the two extremities set nearly at right angles to each other.

G. Juddiana has an elongated skull resembling that of *G. Traquairi*, but the parietal crests are less developed, the bones of the nasal region are much thickened and overlap the nasal apertures, the small tusk is placed a little further back and points more directly downwards, and the pineal fossa is smaller than in either of the other species.

A second generic form is named *Geikia Elginensis*. This is a skull nearly allied to *Ptychognathus*, Owen, but is distinguished by its shorter muzzle and the entire absence of teeth; the upper part of the skull, between the orbits, is also peculiar, forming a deep valley open anteriorly, with a ridge on each side, the anterio

end of which forms a large prominence above and in front of the orbit. The occiput has only one (the lower) post-temporal fossa open on each side. The maxilla is produced into a tooth-like prominence, which occupies a similar position to the tusks of *Gordonia*, but the bone is too thin to have supported a tooth, and in all probability it was covered by a horny beak. The lower jaw has a strong symphysis, a distinct lateral vacuity, and the oral margin, at the foot of each ramus, bears a rugose prominence.

Elginia mirabilis is the name proposed for the skull of a reptile, which, on account of the extreme development of horns and spines, reminds one of the living lizards *Moloch* and *Phrynosoma*. The exterior of this skull is covered in by bony plates, the only apertures being the pair of nostrils, the orbits, and the pineal fossa. The surfaces of the bones are deeply pitted, as in crocodiles and labyrinthodonts. The horns and spines, which vary from ¼ in. to nearly 3 in. in length, are found upon nearly every bone of the exterior. The development of the epiotics, and the arrangement of the external bones, resemble more the Labyrinthodont than the reptilian type of structure; while the palate, on the other hand, conforms more nearly to the Lacertilian type, and, with the exception that the pterygoids are united in front of the pterygoid vacuity, agrees with the palate of *Iguana* and *Sphenodon*. There are four longitudinal ridges along the palate, some of which seem to have carried teeth. The oral margin was armed with a pleurodont dentition, there being on each side about twelve teeth with spatulate crowns, laterally compressed and serrated. With the exception of the smaller number of the teeth, we have here, on a large scale, a repetition of the dentition of *Iguana*. This peculiar skull seems to show affinities with both Labyrinthodonts and Lacertilians, and is unlike any living or fossil form; its nearest, though distant, ally apparently being the *Pareiasaurus* from the Karoo beds of South Africa.

Linnean Society, December 1.—Prof. Stewart, President, in the chair.—A letter was read from the Rev. Leonard Blomefield, expressing his high appreciation of the compliment paid him by the presentation of the illuminated address which had been signed by the Fellows present at the last meeting of the Society and forwarded to him.—Messrs. H. and J. Groves exhibited specimens of several Irish *Characeæ* collected during the past summer. *Nitella tenuissima* from Westmeath and Galway had not been previously recorded from Ireland, and a large form of *N. gracilis* from two lakes in Wicklow had been only once previously met with. Referring to the former, Mr. H. Groves remarked that although it might be expected to occur in all the peat districts it had only been found in two widely separated localities in England, namely, in the Cambridgeshire Fens and in Anglesea.—Mr. A. Lister made some remarks on the nuclei of Mycetozoa, exhibiting some preparations under the microscope.—Mr. E. Cambridge Phillips forwarded for exhibition a hybrid between red and black grouse, which had been shot in August near Brecon.—Mr. J. E. Harting exhibited and made remarks on some coleopterous larvæ which had been vomited by a child at Tintern, and had been forwarded by the medical attendant, Dr. J. Taylor Brown, for identification. The precise species had not been determined, but was considered to be allied to *Blaps mortisaga*. Mr. Harting drew attention to the fact that cases of voiding coleopterous larvæ were mentioned by Kirby and Spence (7th ed. p. 71), and by the late Dr. Spencer Cobbold in his work on parasites (1879, p. 269).—Mr. D. Morris exhibited some tubers of *Calathea allouia*, eaten as potatoes in Trinidad, where it is known as Tapee Nambour. Apparently a corruption from the French *topinambour* (artichoke).—A communication was read from Mr. J. H. Hart, of the Botanic Gardens, Trinidad, on *Œcodoma cephalotes* and the fungi it cultivates.—Prof. F. Jeffry Bell contributed a short paper on a small collection of Crinoids from the Sahul Bank, North Australia, some of which were new, and Mr. Edgar Smith communicated descriptions of some new land shells from Borneo.—The meeting adjourned to December 15.

Physical Society, December 9.—Mr. Walter Baily, Vice-President, in the chair.—The Chairman announced that an extra meeting would be held on January 13, 1893.—Prof. S. P. Thompson's communication on Japanese magic mirrors was postponed.—Mr. W. B. Croft read a paper on the spectra of various orders of colours in Newton's scale. After referring to the definition of the *order* of colours by reference to the retardation in wave-lengths, produced by different thicknesses of selenite between crossed polarizer and analyzer, the author went on to say that several books on optics implied that the number of bands in the spectra of these colours was the same as the order of the colour. On obtaining selenites of the first four orders of red from Messrs. Steeg and Reuter, he found that the first three orders gave one dark band each, and that of the fourth order three dark bands. Further experiments showed that the thicknesses of the selenites were in the proper proportions required to give the first four orders of red. The numbers of bands, the author explained, depended on the numerical possibilities of wave-length within the visible spectrum—that is, whether a multiple of the wave-length of one visible wave can be another multiple of a different wave. For example, taking the visible spectrum as extending from A (0·000760) to H (0·000394) and the wave-length of the line E in the green as 0·000527, it was shown that the first order of red was due to extinction of green by a thickness of crystal proportional to 1 × 0·000527, and would give one band in the green. For the second order, the thickness of crystal was proportional to 2 × 0·000527, viz. 0·001054, and this number was no other integral multiple of any other wave-length between A and H; consequently there could only be one band. Similarly it was shown that the third order of red could only have one band or possibly produce a shortening of the spectrum. With the fourth order of red three bands were obtainable, for 4 × 0·000527 = 3 × 0·000703 and = 5 × 0·000422. Three bands were therefore possible near F, A, G, respectively. At the conclusion of his paper, Mr. Croft directed attention to a very simple form of diffraction apparatus, by which most of the ordinary diffraction phenomena could be well seen, and which also served for spectrum observations. Mr. H. Miers pointed out that in Lewis Wright's "Practical Optics" a chart showing the bands corresponding to the first four orders of red was given. So far as he was aware, the subject was not fully discussed in the book. In reply, Mr. Croft said he had noticed Mr. Wright's chart, but believed the text implied that the number of bands should be the same as the order of the colour. Tyndall made definite statements to that effect.—Dr. W. E. Sumpner read a paper on the diffusion of light. The influence of diffusion in increasing the illumination of rooms and open spaces, had not, in the author's opinion, been sufficiently appreciated. Being impressed with the great importance of the subject, he was led to make determinations of the co-efficients of reflection, absorption, and transmission of diffusing surfaces. To give precision to terms sometimes vaguely used, several definitions were proposed. *Reflecting power* was defined as the ratio of the amount of light reflected from a surface to the total amount of light incident upon it; *illumination* of a surface, as the amount of incident light per unit of surface; *unit quantity* of light as the flux of radiation across unit area of a sphere of unit radius at whose centre a unit light is placed; and *brightness* as the candle-power per unit area in the direction normal to the surface. Denoting these quantities by η, I, Q and B respectively, and assuming the cosine law of diffusion (*i.e.* the candle-power in any direction is proportional to the cosine of the angle between the direction and the normal to the surface) it was shown that $\pi B = \eta I$, and that the average illumination (I′) of the walls of a room is related to the illumination (I) due to the direct action of the lights as expressed by the formula $I' = \frac{I}{1 - \eta}$. If the reflecting power of the walls, &c., be 50 per cent., $\eta = \frac{1}{2}$, and $I' = 2I$, whilst if $\eta = 0{\cdot}8$, a number approximately true for white surfaces, then $I' = 5I$. The illumination due to the walls may, therefore, be far more important than that due to the direct rays from the lights. When the surfaces consist of portions of different reflecting power, the average reflecting power may be found from the equation $\eta = \frac{\eta_1 A_1 + \eta_2 A_2 + \&c.}{A}$, A being the total surface, and A_1, A_2, &c., the areas of surfaces whose reflecting powers are η_1, η_2, &c., respectively. This law is shown to be quite accurate for spherical enclosures. In measuring reflecting power, the surface was attached to a large screen of black velvet placed perpendicular to a 3 metre photometer bench. Two lights were used, one a Methven 2-candle standard placed at the end of the bench remote from the reflecting surface, and the other, a glow lamp of about 20 candle power, was attached to a slider which also carried a Lummer-Brodhun photometer. The glow lamp served to illuminate the reflecting surface, but the photometer was screened from its direct rays. The formulæ used in reducing the observations are worked out in the paper

and tables of results given Absorbing power was determined by measuring the candle-power of a glow lamp, first when uncovered, and then when surrounded by a cylinder of the substance under test It was found to be of great importance to distinguish between apparent and real absorption, for reflection from the surfaces of the cylinders increases the internal illumination The true absorption coefficient (α) is given by $\alpha = (1 - \eta)\dfrac{k_0 - k_1}{k_0}$, where η is the reflecting power and k_1 and k_0 the candle-powers with and without the envelope of material under test In determining transmitting power, the Methven standard and photometer were placed on one side of the surface and the glow lamp on the other Difficulties were experienced from the fact that some materials such as tracing paper, transmit part of the light directly (like transparent substances), and another part by diffusions according to the cosine law Methods for discriminating between the different parts were therefore devised both in the reflection and transmission experiments, and consistent results subsequently obtained Tables and curves showing the close agreement of calculated and observed values, are included in the paper An abstract of some of the tables of numbers is given below —

Material	Percentage reflecting power η	Percentage absorption α	Percentage Transmission τ	$\eta + \alpha + \tau$
Blotting paper	82	13·8	9·2	105·0

Dense opal	—	39		
Ground glass	—	42		

Theoretically the sum of the reflecting, absorbing and transmitting powers should be unity, but from the above table it will be noticed that they exceed 100 per cent, by amounts greater than can be accounted for by experimental error This discrepancy, the author thought, might be attributed to the law of cosines not being exactly fulfilled Mr A P Trotter said he had been interested in the subject of diffusion for many years with a view to obviating the glare of arc lamps Some experiments he made on reflecting power gave unsatisfactory results, owing, as he now saw, to his not taking the solid angles subtended by the reflecting surfaces into account. The reflecting power of substances was of great importance in the illumination of rooms, in one case measured by Dr. Sumpner and himself, two thirds of the total illumination was due to the walls It would greatly simplify measurement of reflecting power if some substance could be adopted as a standard Referring to the cosine law, he said he had found it true, except when the angles of incidence approached 90° In cases where considerable total reflection took place the apparent brightness near the normal direction was greatly in excess of that in other directions. These points he illustrated by polar curves. He had also considered what should be the nature of a roughened or grooved surface to give the cosine law of diffusion. No simple geometrical form of corrugations, &c., seemed to fulfil the required conditions. Dr. Hoffert said the high numbers given for the reflecting powers of substances were very interesting. Most people had noticed the effect of laying a white table cloth in an ordinary room. He had also observed that wall papers of the same pattern, but slightly different in colour, had very different effects in producing increased illumination, and wished to know if the influence of small differences in colour and texture on diffusing power, had been investigated Mr Blakesley defended the cosine law, and suggested that the summation of the powers exceeding unity might be due to the fact that the enclosure reflected heat as well as light, thus raising the temperature and increasing the efficiency of the radiant Mr Addenbrooke said the importance of the subject was impressed on him when he passed through America three years ago and noticed the crude manner in which electric lighting was there carried out If using good reflecting surfaces increased the illumination of a room 50 per cent, it was like reducing the cost of electricity from 8*d* to 4*d* per unit He could hardly conceive any subject of more practical importance than the one before the meeting Dr C V Burton did not understand why the cosine law should be objected to, for it was possible that no surface was perfectly diffusive The effect of reflection from walls, &c, say in illuminating a book would not, he thought, be so great as would appear from the numbers given, for one usually read near a light, and the reflected light falling on the book was only a small part of the whole, on account of the greater distances of the walls Another member pointed out that in experiments such as those described, it was very important to screen the photometer and surfaces from all radiation other than that under test He rather doubted whether any surface reflected as well as mirrors White surfaces might appear to do so, but this was probably because the eye would overestimate it, owing to the superiority of white in aiding distinct vision Dr Sumpner in reply said he had, as stated in the paper, used white blotting paper as a standard of reflecting power and found it very convenient His most careful measurements had been made on whitish surfaces and not on coloured ones Where one colour, say red, preponderates in a room, the average light would be much redder than that emitted by the source owing to the other colours being absorbed In considering illumination as related to distinct vision, it was necessary to take account of the eye itself, for the pupil contracted in strong lights and opened in feeble ones This subject he hoped to treat fully in a subsequent paper

Entomological Society, December 7 —Frederick DuCane Godman, F R S, President, in the chair —The President announced the death, on December 2, of Mr Henry T Stainton, F R S, an ex President and ex Secretary of the Society —Mr Jenner Weir exhibited a species of Acræa from Sierra Leone, which Mr Roland Trimen, F R S, who had examined the specimen, considered to be a remarkable variety of *Telchinia encedon*, Linn It was a very close mimic of *Limnas alcippus*, the usual West African form of *Limnas chrysippus* The upper wings of the specimen were rufous and the lower white, as in the model, and the resemblance in other respects was heightened by the almost total suppression of the black spots in the disc of the upper wings, characteristic of the usual markings of *T encedon* —Mr F J Hanbury exhibited a remarkable variety of *Lycæna adonis*, caught in Kent this year, with only one large spot on the under side of each upper wing, and the spots on the lower wings entirely replaced by suffused white patches He also exhibited two specimens of *Noctua xanthographa* of a remarkably pale brownish grey colour, approaching a dirty white, obtained in Essex, in 1891, and a variety of *Acronycta rumicis*, also taken in Essex, with a dark hind margin to the fore wings.—Mr H J Elwes exhibited a living specimen of a species of *Conocephalus*, a genus of *Locustidæ*, several species of which, Mr McLachlan stated, had been found alive in hothouses in this country —Dr T A Chapman exhibited immature specimens of *Tæniocampa gracilis*, *T. gothica*, *T populeti*, *T. munda*, *T instabilis* and *T. leucographa*, which had been taken out of their cocoons in the autumn, with the object of showing the then state of development of the imagos —Mr F W Frohawk exhibited a living specimen of the larva of *Carterocephalus palæmon* (*Hesperia paniscus*) hybernating on a species of grass which he believed to be *Bromus asper* The Rev Canon Fowler and Mr H Goss expressed their interest at seeing the larva of this local species, the imagos of which they had respectively collected in certain woods in Lincolnshire and Northamptonshire. Mr Goss stated that the food-plants of the species were supposed to be *Plantago major* and *Cynosurus cristatus*, but that the larva might possibly feed on *Bromus asper* —Mr C G Barrett exhibited a long series of remarkable melanic varieties of *Boarmia repandata*, bred

by Mr A E Hall from larvæ collected near Sheffield —Mr W Farren exhibited four varieties of *Papilio machaon* from Wicken Fen, also a series of two or three species of *Nepticula* pinned on pith with the "minutien Nadeln," for the purpose of showing these pins —Canon Fowler exhibited specimens of *Xyleborus perforans*, Woll which had been devastating the sugar canes in the West Indies —Mr E B Poulton, F R S, showed, by means of the oxy-hydrogen lantern, slides of various larvæ and pupæ, in illustration of his paper, read at the October meeting, entitled, "Further experiments upon the colour-relation between certain lepidopterous larvæ and their surroundings" He stated that he believed that nineteen out of twenty larvæ of *Geometridæ* possessed the power of colour adjustment Mr F Merrifield, the Rev J Seymour St John, and Mr Jacoby took part in the discussion which ensued —Mr F. Merrifield read a paper entitled, "The effects of temperature on the colouring of *Pieris napi*, *Vanessa atalanta*, *Chrysophanus phlæas* and *Ephyra punctata*," and exhibited many specimens thus affected Mr Poulton, Dr F A Dixey, Mr. Elwes, and Mr Jenner Weir took part in the discussion which ensued —Mr Kenneth J Morton communicated a paper entitled, "Notes on *Hydroptilidæ* belonging to the European Fauna, with descriptions of new species"—Dr T A Chapman read a paper entitled, "On some neglected points in the structure of the pupa of Heterocerous Lepidoptera, and their probable value in classification, with some associated observations on larval prolegs" Mr Poulton, Mr Tutt, Mr Hampson, and Mr Gahan took part in the discussion which ensued —Mr J Cosmo-Melvill communicated a paper entitled, "Description of a new species of butterfly of the genus *Calinaga*, from Siam"—Mr W L Distant communicated a paper entitled, "Descriptions of new genera and species of Neotropical *Rhynchota*."

GORE'S "VISIBLE UNIVERSE"

The Visible Universe By J Ellard Gore, F R A S (London Crosby Lockwood and Son, 1893)

THE object of this book is "not to propound any new hypothesis, but simply to explain and discuss theories which have been supported by well-known astronomers and other men of science" as to the "evolution of the Solar System," and to give a popular account of the "construction of the Universe *as we see it*, and its probable development from pre-existent matter"

Mr Gore has already acquired considerable success as a popular writer on astronomical subjects, and the scheme of the present volume is, as we might expect, a very good one The first three chapters are devoted to a popular account of the hypotheses of Kant and Laplace, the principal objections that have been urged against them, and the modifications and additions suggested by recent research In subsequent chapters such subjects as the fuel of the sun, the luminiferous ether, the constitution of matter, celestial chemistry, and the meteoritic hypothesis are dealt with Mr Gore then reaches the purely descriptive portion of his subject, and gives excellent chapters on the Milky Way, and on "the latest results respecting the distribution of stars and nebulæ and their relative motions" Various theories of the construction of the Universe are then discussed, and in a final chapter the idea of infinite space and a finite universe is developed

Although the general scheme of the book is excellent, the execution falls in many places far short of its promise and our expectations When Mr Gore confines himself to the historical and descriptive his work is, on the whole, well done, but in discussing theories he has in several cases obviously ventured out of his depth, and has consequently spoiled what would otherwise have been a valuable addition to popular astronomical literature

For his chapters on the Nebular Hypothesis and Faye's theory of the formation of the solar system Mr Gore has largely availed himself of M Wolf's "Les Hypothèses Cosmogoniques" He has also introduced extensive quotations from "the late Mr Jacob Ennis," but in considering Ennis as an authority, Mr Gore is probably alone Mr Ennis was, on his own admission, not a mathematician, and certainly did not by "his own discoveries," place the nebular hypothesis on a firm mathematical basis. He proved Mars could not have satellites; that the heat of the sun was entirely due to chemical combination; that Sirius has twelve planetary attendants, and made several other equally important discoveries *His* mathematical demonstration of the truth of the nebular hypothesis is about as sound as the well-known proofs that the earth's surface is flat. Mr Gore would have done well to have omitted the quotations from Ennis, and to have filled the space with a fuller account of the recent mathematical investigations of the nebular hypothesis, especially those of Prof. G H Darwin.

Quoting freely from Young and Sir William Thomson, Mr Gore is fairly safe in his chapter on the fuel of the sun, but he is in error in stating that "the meteoric theory of the sun's heat must be abandoned" It is true that the larger portion of the solar heat is believed to be due to shrinkage, but it is generally conceded that a considerable fraction has its origin in falls of meteoric matter into the sun A glaring case of the misuse of a scientific term occurs in this chapter (p 52), where Mr Gore is responsible for the statement that "the theory generally held by astronomers ascribes the heat of the sun to shrinkage of its *mass* caused by gravitation" Mr Gore surely meant volume

The chapter on celestial chemistry is meagre and unsatisfactory It seems incredible that the application of photography to spectroscopic work is not even mentioned, and that no allusion is made to the Draper catalogue of photographic stellar spectra, to Rowland's photographic map of the solar spectrum, or to any of the recent photographic work Mr Gore is also in error in this chapter when he states (p 79) that although the great nebula in Andromeda "has never been resolved into stars the evidence of the spectroscope shows it is not gaseous" Bright bands have been seen in the spectrum by Backhouse Fowler, and myself, and these have been identified as probably due to carbon radiation

The Meteoritic Hypothesis is dealt with in considerable detail, and here Mr Gore is most seriously in error He gives what is professedly "a review of the principal facts and arguments advanced by Lockyer," and carefully enumerates all the objections that have been urged by "his opponents," ending the account with the opinion that "on the whole, therefore, we seem bound to conclude that the weight of evidence is against the truth of the Meteoritic Hypothesis." The chapter bears internal evidence that Mr Gore began his consideration of this hypothesis with the opinion which he enunciates as his final judgment, already formed

The summary of Prof Lockyer's book has not been made with the care that should have been bestowed upon it There are at least two misquotations, on p 91, the substitution of "periastron" for "perihelion" makes nonsense of what is otherwise an important paragraph, and on p 113 the omission of the word "other" considerably modifies the meaning of the passage quoted

There are several errors due to hasty compilation, observations and theories being attributed to Prof Lockyer in cases where be only quotes the observations and adopts the theories. On p 92 Mr Gore says "he (Lockyer) also finds line absorption in Comet Wells and the great September comet of 1882" This is misleading, the observations of absorption having been made by Copeland, Maunder, and Vogel On p 93 we find the "theory that the light of comets is due to collisions between the component meteorites" attributed to Prof Lockyer The theory is due to Reichenbach, Tait, and Sir William Thomson, Prof Lockyer's contribution being the demonstration that spectroscopic observations lead to and support the hypothesis The results of Tait's calculations given on pp. 227–229 of the "Meteoritic Hypothesis" are also attributed to Lockyer on p 93 of Mr Gore's book On p 95 we read, "the spectra of the true nebulæ consist of a very faint continuous spectrum crossed by one, two, three, or four bright lines" Lockyer gives seventeen bright lines in his table Mr Gore's footnote that "the complete hydrogen series of lines were

photographed by Dr Huggins in 1890," in the great nebula in Orion is also a mistake

Mr Gore has evidently failed to appreciate the importance of several portions of Prof Lockyer's book, and has consequently omitted to mention them in his summary Thus the observations of meteoritic glows recorded on pp 49-51 of the "Meteoritic Hypothesis" are entirely passed over In these experiments it was found that on slowly warming meteorites in a vacuum tube through which electric discharges were passing, the spectrum of hydrogen was first developed, then carbon was added, and the first line due to any metal was the 500 line which is the characteristic nebular line Further heating gave the 495 line and then the B magnesium lines These experiments, omitted in Mr Gore's summary, are an effective answer to the objections of Messrs Liveing and Dewar given on p. 116 of this book, for we have here the 500 line developed in presence of hydrogen, and at a lower temperature than the B lines

Mr. Gore believes that "one of the crucial tests of the meteoritic hypothesis" is the question of the identity of the 500 nebular line with the magnesium fluting at this wave-length He says (p 86) that "it is on the identity of this fluting (or rather its brightest edge) with the chief line in the spectrum of the nebulæ that the meteoritic hypothesis mainly depends," and from pp 118-121 it is obvious that he thinks the evidence conclusively against the hypothesis on this point

In the first case the identity of the 500 nebular line with magnesium is not essential to the meteoritic hypothesis, although the latest observations have strongly supported the case for the identity The main point is whether the 500 nebular line is due to high or to low temperature, and whether nebulæ are high or low temperature phenomena. Previous to the publication of Prof Lockyer's book all cosmical bodies were believed to be cooling The nebulæ were considered to be the hottest of all bodies, and on losing heat were supposed to pass into stars of the Sirian type Further loss of heat converted them into stars of the solar type, and by still further loss they became red stars with banded spectra before reaching final extinction This hypothesis was supplemented by Dr Croll, who suggested that nebulæ were formed by the complete and almost instantaneous volatilisation of these dark bodies on collision, the heat generated by impact being sufficient for the purpose Lockyer's hypothesis supposes nebulæ to be loose swarms of colliding meteorites Condensation of these swarms by gravitation increases the number of collisions, and as the temperature rises we get *stars* with bright lines in their spectra. Further increase of temperature gives red stars of Secchi's III class, which pass with still rising temperature into stars with fine absorption lines in their spectra, and so on until the Sirian type is reached, in which we have the highest temperature. Collisions have now ceased and the process of cooling begins, the stars passing into the solar type, then into red stars of Secchi's IV class, and to final extinction.

The lines in the spectra of nebulæ and bright line stars according to this theory may be due to three causes (*a*) Radiating vapours filling the interspaces between the meteorites; the lines of hydrogen and the bands of carbon being due to these (*b*) *Low temperature* lines of metals, due to grazing collisions of meteorites (*c*) High temperature lines of metals, due to direct collisions It is essential to the theory that low temperature lines o metals should be found in nebulæ spectra, and the low temperature origin of the 500 line seems clearly established Its chemical origin is of quite secondary importance That it is due to low temperature is shown by the experiments on meteoritic glows which Mr Gore omits, by its presence in comets away from the sun, as observed by Huggins in 1866 and 1867 (this being the only line present), by Vogel in Coggia's comet, and Konkoly in the great September comet of 1882, and also by the fact that it persists in all temporary stars as the temperature falls and is the last line to disappear Until these facts are explained away the foundation of the meteoritic hypothesis remains unshaken Mr Gore seems unaware that this main point is now generally admitted, for although the low temperature origin of nebulæ was denied by Dr Huggins as late as 1889, it was adopted in his Address to the British Association at Cardiff in 1892

There is early evidence in the book that Mr Gore has entirely failed to grasp this essential point of the hypothesis On p 41, discussing Croll's impact theory of the formation of nebulæ, he says, "according to Prof Lockyer the temperature of the original solar nebula was as high as that of the sun at present" Mr Gore would have done well to have noted that on p 528 of his book Prof Lockyer explicitly states that "the temperature of the most prominent radiating vapours in nebulæ is about that of the Bunsen burner"

Mr. Gore's misconception of the theory and the spirit in which he approached its discussion are also shown on p 101, where he says, "All these conclusions rest, of course, on the supposed coincidence of certain lines in the spectra of comets, nebulæ, and stars, with bright lines and flutings, a coincidence which has been disputed by other observers Relying, however, on the accuracy of his experiments, Lockyer proposes a new grouping of cosmical bodies He supposes some of these bodies to be increasing in temperature, while others—like our own sun—are cooling" To this he adds a footnote, "Lockyer's curve rests on this assumption, but it should be stated that some astronomers doubt that the sun is really cooling" We should be glad to know who these "astronomers" are Mr Gore himself is evidently not of their number, for he distinctly recognizes the sun as a cooling body in his chapter on the fuel of the sun, and specially mentions it as such on pp 42 and 53. It is possible that Mr Gore has misunderstood the apparently paradoxical fact that a body, in changing from a gas to a liquid, may rise in temperature while losing heat, but that will not justify the loose style which leaves it to be understood by the general reader that Lockyer's curve rests solely on his experiments, and the "assumption" that the sun is cooling, and that this fact is doubted by some astronomers We are quite aware that Mr Gore's expression will bear other interpretations, but this is the idea conveyed to several readers to whom we have shown the book.

Returning to the question of the coincidence of the 500 nebular line with magnesium, the evidence recorded by Mr Gore is in favour of, rather than against, the identity.

His facts are —Huggins finds the wave-length in the Orion nebula as 5004·75, the magnesium fluting being 5006·5, a difference of 1·75. At the same time, Huggins finds very little, if any, sensible motion in the line of sight. Mr. Keeler finds as a mean from 10 nebulæ 5005·68, magnesium being, according to his measurement, 5006·36, a difference of ·68. These latter observations completely invalidate Huggins's evidence on this point, especially as Mr. Keeler recognizes a motion of recession for the Orion nebula of 10·7 miles per second.

Mr. Gore ought to have recorded the fact that in Keeler's observations the comparisons for different nebulæ gave the magnesium sometimes more refrangible and sometimes less refrangible than the nebular line. Later observations of Keeler, "corrected for the earth's orbital motion and the sun's motion," give the nebular line a wave-length of 5005·93, *i.e.* only ·43 from the magnesium. Assuming Keeler's latest results as perfectly correct, and placing his position at Charing Cross, while representing the position found for this line by Dr. Huggins in 1868 at St. Paul's Cathedral, we find Dr. Huggins's limiting positions in 1889 as the extreme east and extreme west ends of Green Park, his 1890 position in the middle of Green Park, while the magnesium fluting will be at Cecil Street. When we consider that a motion in the line of sight of less than twenty miles per second will make the nebular line and the magnesium fluting absolutely coincident, that the rate of the sun's motion in space is estimated but not absolutely known, that these measurements are probably the most difficult of all astronomical observations, and that every increase of power and accuracy has brought the lines closer together, we are certainly *not* justified in stating that the "weight of evidence" is "against the truth of the hypothesis." The differences in recorded wave-lengths of well-known solar lines by experienced observers are in many cases greater than the difference in question here.

Mr. Gore regards the dispersion used by Prof. Lockyer as insufficient, and yet he records that sixteen prisms were used by Lockyer in some of his observations of the coincidence of the nebular line with magnesium, so that his dispersion was actually greater than that used by Dr. Huggins, and two-thirds that of Mr. Keeler, whose dispersion equalled twenty-four prisms.

The objections to that portion of the meteoritic hypothesis which deals with the meteoritic origin of the lines in the auroral spectrum do not in any way affect the main hypothesis. That this subject is unimportant is distinctly recognized by Prof. Lockyer, "Meteoritic Hypothesis," p. 97, where he claims that "certainly the coincidence is such as to justify us in regarding meteoritic dust as the origin of the spectrum *until a better and more probable origin is demonstrated*."

We are told (p. 122) that Mr. Monck objects to Lockyer's hypothesis, because it contains no explanation of "why all the planets and asteroids and the great majority of the satellites revolve in the same direction, why the orbits of the larger bodies of the system deviate so little from the circle and why they are so nearly in the same plane." This was asked in 1890, and yet Prof. G. H. Darwin had in 1888 shown that a swarm of meteorites which, on the meteoritic hypothesis would form a nebula, may be considered as a gas, and therefore any answer that the nebular hypothesis can give to these questions will also apply to the meteoritic hypothesis.

Such puerile suggestions as that the meteorites used by Prof. Lockyer "*may have been*" of terrestrial origin: "that meteor clouds dense enough to produce the requisite amount of light by their collisions would also be dense enough to intercept *a great part of it* again on its way to the earth" (the italics are ours); and objections based on Mr. Monck's interpretation of Prof. Newton's calculations, and on opinions to which Mr. Monck "*inclines*" as to the origin of certain comets, are evidence that Mr. Gore has not hesitated to avail himself of anything that in any way seems to disagree with the meteoritic hypothesis. The whole of the "objections" of the "opponents" of Prof. Lockyer recorded by Mr. Gore are on matters of secondary importance, and have been insisted upon by him owing to his complete misconception of the theory. As a guide to the meteoritic hypothesis his chapter is misleading, and utterly valueless either as exposition or as criticism.

After his account of the meteoritic hypothesis Mr. Gore abruptly turns to a comparison of the various drawings that have been made of the Milky Way, and gives an interesting and valuable summary of the present state of our knowledge as to star distribution and movement and the construction of the Universe. For this portion of the book we have nothing but praise. It is carefully written and copiously illustrated. Mr. Gore has evidently taken the word "visible" in its widest possible sense, for he includes not only things visible to the retina of the eye, but those visible to the retina of the camera; and six excellent reproductions of photographs of nebulæ and stars clearly demonstrate the superiority of the latter for astronomical purposes. It is probable that the use of photography in the preparation of complete charts of the Milky Way will throw much new light upon many of the points discussed in this portion of the book, and may profoundly modify many of the views at present held; but in presenting a clear and concise account of the present state of our knowledge Mr. Gore has made a valuable addition to the literature of the subject. An appendix, in which are given various calculations and tables involved in the discussion of several points raised in the book, and a useful index, complete the volume.

A. TAYLOR.

THE IRON MANUFACTURE IN AMERICA

On the American Iron Trade and its Progress during Sixteen Years. By Sir Lowthian Bell, F.R.S. (Edinburgh and London: Ballantyne, Hanson, and Co.)

IT is impossible, in the limited space at our disposal, adequately to review this remarkable book, in which no branch of a very comprehensive subject appears to have escaped the author's close attention.

So full of detail and so exhaustive of the subject-matter are the various sections into which the work is divided, that we can do little more than glance at the numerous subdivisions.

The first section, dealing with international trade, dis-

cusses at length the American policy of protection Comparison is made of American exports as affected by British free trade Then follows a series of short articles on various subjects—the Anglo-American, imports of tinplates from this country, imports and exports of both countries, America as consumer and as exporter, and other important matters By way of illustration copious tables are adduced with the author's deductions therefrom, and these will well reward the closest attention.

Section 2 deals with the relative cost of the necessaries of life in various mining and metallurgical localities —

"In the United States the manufacturers are enriched at the expense of the agriculturist and of other consumers. Some time before the abolition of protective duties in the United Kingdom years of scanty harvests entailed a great amount of misery among the labouring population of these islands, and at all times the landed interest by the protection granted to it by law, imposed a burthen upon industry generally This relation between land and industry is now, as we have seen, reversed in the United States, by which, according to our views, the manufacturers are enriched at the expense of the agriculturists and of other consumers

"Circumstances have greatly changed since the repeal of the corn laws, and the general introduction of free trade in the British Isles, for we have a people, the largest food importers in the world, obtaining their supplies 3000 miles from where they are grown, frequently at prices as favourable as those charged in the cities of America itself"

Sir Lowthian Bell appears to grasp fully a difficult situation, and gives a fair summary of the relative economic position of the two countries, and though his views will hardly be endorsed in their entirety by Americans, the present statement of them cannot fail to strengthen the movement now in progress towards a modification of the existing fiscal policy

It is somewhat out of our province here to comment upon the protective policy so ardently advocated in America, but we are of opinion that had iron manufacturers in the States adopted, even partially, our policy of free competition, they and their *employés* would now have been in a stronger position, and would have had a better prospect of successfully competing with us It is possible that the very natural desire to foster the home industry has carried them a little too far

In the next section the assemblage of materials on American is compared with that on British railways in an exhaustive manner

Section 5 treats of the iron ores of the States, and is fully illustrated with maps, topographic and geological, together with the coal fields The quantities raised at different periods are given, and show that in ten years the production of ore has been fully doubled This is followed by a detailed account of the mines and costs of working Pages 96-104 contain some interesting speculative matter on the genesis of iron ores, the cost of raising ore, together with chemical analyses, is compared with that of Great Britain and other countries. The importance of having iron free from phosphorus is shown It is noted that iron ore suitable for the Bessemer acid process has been imported In 1880 only 27 35 per cent of native ore was deemed suitable and raised for this purpose

Treating of raw material in the States, the writer gives a vivid picture of the boundless wealth of both ore and fuel existing within a limited area In the great Lake district there is a wide strip of country over 1000 miles long, where ore is found, and this is insignificant when compared with the immense resources of fuel The origin of natural gas, petroleum, and its uses receive attention —"natural gas is not a suitable form of fuel for the blast furnace"

Section 9, on the manufacture of coke, is interesting At the outset coke is defined and compared with its analogues—anthracite or native coke The losses necessarily entailed in the manufacture of coke are discussed, together with modes of minimizing them It is shown that it is impossible to utilise the gases evolved in coking or heating coal in the blast furnace, and how slowly this was realized in early practice

Here the author's ripe experience comes into play The *rationale* of coking is tersely put, together with the methods dealing with the utilization and recovery of the ammonia, tar, &c, the products of the destructive distillation of coal, "or coking," with special appliances adapted for this purpose The comparative merits of hard and soft coke in the blast furnace are discussed Commercial details are appended, which speak for themselves, and which appear accurate

From the section on the manufacture of pig iron it may be gathered that the gigantic methods of procedure, and the enormous energy diplayed in the business of the American iron manufacture, leave the average cautious Englishman in the rear There is, however, the reverse side for consideration it is questionable whether even the magnificent results before us have not been purchased at too great a cost Enormous quantities of iron have without doubt been turned out, such as would never have been dreamt of here, but it would seem that authorities are not yet in agreement as to the relative merit of English and American practice So far our American cousins appear satisfied, pointing triumphantly to the saving of both time and material accruing from their present practice At the Edgar Thompson Works (page 170) one of the furnaces ran 2462 tons of iron in one week, and showed an average make of 2813 tons per week with an expenditure of only 16 80 cwts of coke per ton of iron One needs, however, only to take Sir L Bell's elaborate demonstration of the laws which govern the consumption of fuel in the blast furnace, and its utilization for the reduction of the ore, to see clearly that the above production is scarcely in the domain of practical work, carried out under ordinary conditions with average ores and fuel. Also (p 162) he remarks, if Great Britain fails to offer striking examples such as are described by Mr. Potter and Mr Gayley, yet, all things considered, a more uniform as well as loftier pitch of excellence in British furnace work can be proved

Our space does not admit of a complete statement of Sir L. Bell's proofs, shortly, he first tabulates the work done at Middlesbrough with that of the Pittsburg blast furnace, and absolutely demonstrates that the large makes are not altogether due to superior practice. A perusal of the tabular statement given satisfactorily accounts for the larger consumption of fuel in the English furnace.

The poorer ore of Cleveland consumes 3 48 cwt of coke, as against only 1 42 cwt in the richer ore used at Pittsburg for the future of the slag

The quantity of slag determines the fuel required for its consumption, and here is the chief difference in the amount of fuel required, amounting to 2 06 cwts The Clarence furnace consumed 19 99 cwt of coke per ton of iron, the Pittsburg furnace consumed 16 80, difference 3 19, and deducting 2 06 from 19 99 cwt = 17 93, showing an excess of 1 13 against the English furnace This is practically the only margin we have for economy in the other sources of waste tabulated in Sir L Bell's comparison of heat distribution

A positive saving is effected of only 1 13 cwt, and reasons are given showing that, all things considered, this may be counterbalanced by the increased expenses incurred in American practice As instance pp 172-174 there are now four furnaces in action at the Clarence works performing duty well after 17½ years' service, as against the hard-driven furnaces in America with lining worn out, and useless in one-sixth of the period

The limitation is well defined in the following words, pp 182-183 —

"As one who has been fifty years at blast furnaces, I am greatly impressed with the pitch of excellence to which the Americans have brought this useful invention

"While saying so much I have not in my mind the enormous makes

"In respect to this we must remember that neither in materials nor in labour can we look for any economy in this country

"On the subject of large makes I must admit that I failed to shake the belief of my friend, Mr E C. Patter, that there is a great advantage in tasking the endurance of the furnace to the extent of reducing it to a wreck about every three years

"I cannot say I am quite a convert to his creed, but recent experience, and the unswerving conviction of my American friends, have raised in my mind the disposition to make a trial of Cleveland ironstone, on what I have thought a questionable mode of action"

The question of heat intensity, or actual temperature, which must vary with the rate at which the fuel or coke is consumed, has not been mooted, and we admit there is no positive reason why it should

Yet it is evident that a certain fuel—coke, for instance —may be so burnt as only to give a heat intensity barely sufficing for the fusion of lead On the other hand, it may be so manipulated, *i e* rapidly consumed by a quick draught or forced blast "as to attain a heat intensity (temperature) sufficing for the fusion of pig iron."

Working with high pressure blast and driving in a large volume of air (87 15 cwts. Clarence, as against 71 20 cwts. Pittsburg, see p. 172), the heat intensity must be greater in the latter instance, and must, "according to the law of heat exchanges," result in the more rapid economic fusion of iron in the hearth, also intensifying the usual chemical reactions. This seems worth consideration; temperature is an important factor—in saying this it must not be inferred that the estimation of the calorics which a given fuel evolves, and their distribution, must be set aside; on the contrary, they remain the fundamental basis of any study bearing on the economic uses of fuel Finally, one gathers on the whole that American practice is not universally superior to ours, and competent authorities are as a rule inclined to a compromise In other words we might graft or partially adapt their practice to ours, so reaping the benefits of both, for something may be urged in favour of either system

JOHN PARRY

A COUNTY FAUNA

The Fauna and Flora of Gloucestershire By Charles A Witchell and W Bishop Strugnell (Stroud James, 1892)

IT would really be almost difficult to discuss this book in a serious spirit were it not that the publication of so ambitious a work as the Natural History of a County must always be regarded as a serious undertaking The reader who has struggled through the volume will lay it down with a sigh—not of regret at leaving it, but at the thought that time has been wasted in its compilation

A glance at the index is almost enough to condemn the book, without making any attempt at further acquaintance Among nearly a score of errors in spelling, *subuteo, oesalon, tinninculus*, occur as three consecutive words Nor is this carelessness by any means confined to the index Such blemishes disfigure the book from beginning to end; and when, among a host of errors, we find such mistakes as *haliotidæ* and *helliborus*, we can hardly ascribe all the blame to the printer The compilers usually give us "Cotteswold," but in the introduction the name is spelt "Cotswold," and there are pages on which both forms occur—in one case only a line apart

A more serious fault is the want of balance in the work. The space allotted to birds occupies eighty-two pages, while the chapter on ants takes up nearly twenty, and that on wasps and bees close upon fifty pages We may say at once that the two latter are so good, and stand out in such marked contrast to the rest of the work that, in spite of their disproportionate length, we hardly grudge a line of the room they occupy Perhaps, however, it is the length of these papers which makes one of the writers on mosses omit "many other interesting species," for want of space Another contributor calls his list of fungi "short and very imperfect" If the list is as complete as it is possible to make it, no one can fairly complain of its shortness; but surely it is scarcely worth while to print an avowedly imperfect list in what professes to be a County Flora

The fauna opens with a brief account of the bats, a mere list of names, among which we look in vain for any evidence of observation. The notices of the quadrupeds contain some interesting particulars, but they present little that is new In the article on the badger a good deal of information is given on the authority of a gentleman who appears to think no observations but his own are worthy of credence One of his own observations is thus worded: "Any one who has caught badgers at night knows only too well that it is certain death to a dog

which is good enough to hold it in the open to follow it into an open drain large enough for the dog to reach it." Other people who have hunted badgers have found that an extremely small terrier is quite able to turn a badger from its earth, and that although the dog may be hurt, even seriously, by its formidable antagonist, the contest does not by any means mean "certain death" to it.

The chapter on birds bears evidence of having been put together in the most casual manner Various contributors have sent in notes as to whether, in their experience, birds were rare or not, and these appear to have been printed without any attempt at summarizing The result is that the whinchat is described in one line as "common," and in the next as "occasionally seen" The marsh tit is "rare," and also "generally distributed" The cirl bunting is in one line called "rare" and "by no means rare" The coot is "rare" (!) and "frequently met with" The woodcock, according to one observer, "has been seen" If it were clear that such remarks applied to different parts of the county, there might be some sense in printing them. As they stand, they are useless and bewildering One contributor is surprised at the occurrence of the gannet just outside the limits of the county, because "they generally inhabit the Bass Rock"! They certainly do, and "there's milestones on the Dover road" But perhaps there is nothing in the whole chapter which quite comes up to what we read about two starlings that one of the contributors watched "fighting furiously each bird trying to force its bill into that of the other *He was informed that the purpose of each bird was by this means to render the opponent insensible, so as to be more easily destroyed*"

In the article on reptiles occur these remarkable words —"The slowworm is habitually 'slow,' but we know of no reptile or quadruped which, in proportion to its size, can move more rapidly"

There are several errors in spelling in the list of land and fresh-water shells, and it is rather misleading to give "Downs, under stones," for the habitat of the species here called *Bacutus*, without adding "near the sea."

Helianthemum polifolium is given as a Gloucestershire plant It would be interesting to know if this is correct The localities usually given are in Somerset and Devon

Among the illustrations are some interesting figures of famous trees; but it seems hardly worth while to have inserted such a very ordinary-looking plate as that of the common crayfish

Allusion has already been made to two chapters the excellence of which is all the more marked by contrast with the grandiloquent flights and the trivial details of much of this unfortunate volume Rev W F White's paper on ants contains, as might be expected, accounts of many interesting and original observations Mr Vincent Perkins's excellent chapter on wasps and bees, again, is extremely good, though the writer deals only with the neighbourhood of Wotton-under-Edge That so imperfect, and, as far as much of its contents goes, we are afraid we must say untrustworthy, a book should ever have been published is matter for regret The real "Fauna and Flora of the County of Gloucester" yet remains to be written.

OUR BOOK SHELF

The Chemistry of Life and Health "University Extension Manuals" By C W Kimmins, M A, D Sc., Staff Lecturer in Chemistry, Cambridge University Extension Scheme (London Methuen and Co, 1892)

THIS little book is well adapted to secure the aim of the author, which is "to give sufficient information on the particular portions of the sciences involved to enable readers to appreciate fully the fundamental principles of hygiene" There can be no doubt of the importance, one might truly say, the national importance, of the spread of sound knowledge regarding the laws of health Such sound knowledge cannot be attained except it be built upon a well-laid foundation of chemistry and physiology To lay the foundation, and rear the structure, in a little book of 160 pages is almost impossible Dr Kimmins has, wisely, omitted much, but what he retains is of fundamental importance, his facts are clearly enunciated and systematically arranged A careful study of this book, especially when it is supplemented, as it is meant to be, by a course of lectures, cannot fail to be most useful The book is written for ordinary people, not for professional students, the teaching is sound and clear The first chapter, on the principles of chemistry, is the least satisfactory in the book, but in this chapter the author has attempted, what is surely unattainable, to give an elementary knowledge of the features of chemical action, the use of chemical symbols, and the molecular and atomic theory, in sixteen small pages As an introduction to the study of the application of chemical facts and principles to the conditions of healthy life, the book is to be thoroughly recommended

Naked-Eye Botany, with Illustrations and Floral Problems By F E Kitchener, M A Pp 182 and fifty-two woodcuts in the text (London, Percival and Co, 1892)

ON turning over the pages of this book one wonders why "Naked-Eye Botany" was chosen for the title, because, although a small book, it has some reference at least to a great many things that cannot be seen with the naked eye It is something in the way of Prof D Oliver's "Lessons in Elementary Botany," but one misses the Professor in it. On p 7 we are introduced to stomata, and physiological processes are described in some detail Nevertheless it contains much useful matter, and with a little revision and better selections would make a very good first book For example, the chickweed is chosen for the first lesson But the flowers of this plant are so small and the number of parts in the various floral whorls is so variable that it is not a good subject to begin with The "problems," or questions, also at the end of each chapter are too wide-reaching Referring to *Aspidium Filix-mas*, we are told that the "production of the fertilized seed, more correctly called oosphere, from the prothallus, can scarcely be made out with the naked eye." Saying nothing about the name given to the fertilized body, we must protest that "scarcely" is not the word to qualify the observation

Perhaps it is too much to ask that the headmaster of a "high school" should be acquainted with even remotely recent discoveries in physiological botany, but it would not be unreasonable to ask him to use the text-books of specialists It is now some years since the reproduction of *Lycopodium* was fully described, yet Mr. Kitchener still teaches that the spores are of two sorts

The Great World's Farm, some account of Nature's Crops and how they are Grown By Selina Gaye (London Seeley, 1893.)

THIS is a delightful book, pleasantly written, full of information, and on the whole remarkably free from those errors, generally the results of misunderstanding, which

are the sins that do so easily beset writers on popular science The volume, which contains some excellent illustrations, deals with "pioneer labourers," "soil-makers," "soil-carriers," "soil-binders," "field-labourers," "guests welcome and unwelcome," "nature's militia," and so forth We do not propose to tell who or what the labourers, the guests, or the militia are. We advise those of our readers who are interested in the transactions of the Great World's Farm to get the volume and ascertain for themselves

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Measurement of Distances of Binary Stars

SOME years ago I communicated to a few astronomers a plan for measuring the distance which separates us from some of the binary stars, believing, as I did, that by using the diameters of their paths as a basis, determinations of distance could be made which are impossible with the means at present in use

This basis could, I hoped, be calculated by first ascertaining the velocities with which the stars are moving in their paths, in a somewhat similar manner to that employed for measuring the motions of stars with the spectroscope, except that instead of making a comparison with a hydrogen flame, the spectra of the two stars should be compared by photographing them together The width of any double lines, which may show themselves (the one line belonging to the spectrum of the receding star, and the other to the advancing one) would be a measure of their velocities expressed in miles. Applying this information to the known period of revolution of the system, its diameter can also be expressed in miles, and this would enable one to estimate the distance from the earth if the angle between the two stars were known This suggestion has already borne fruit, the relative velocity of some rapid, but as yet inseparable, binaries having recently been determined

The answers received to my suggestions were discouraging, but since then instruments have been improved, and I trust that you will think the matter of sufficient importance to be brought before the notice of your numerous astronomical readers Should any of them be able to make the necessary determination, a foundation-stone will have been laid, not only for obtaining a true idea of perhaps undreamt of stellar distances, but also of the masses of binary stars, and possibly a connection may ultimately be traced between them and the adjoining ones

The two most brilliant binary stars are α Centauri and α Geminorum, and as in both these cases the paths are elongated ellipses, and the stars near their extremities, efforts should be directed towards determining their distances as suggested above C E STROMEYER.

Strawberry Hill, November 16

Remarkable Weapons of Defence

THE following extract from a letter from such a careful observer as Mr E E. Green is of such general and special interest as to require publication

Mr R J Pocock informs me that the Acaroid is almost certainly *Holothyrus coccinella*, Gerv , a species that appears to be common in Mauritius, and that in the lateral membranous area between the carapace and the cephalothoracic limbs is a distinct orifice which was regarded by Dr Thorell as of respiratory import, but in connection with Mr Green's interesting discovery of the existence of offensive glands in this animal it is necessary to bear in mind the possibility of its being the outlet of these organs.

The mite has such a hard integument, that being taken into the mouths of the lizards and birds that would probably prey upon it in the situations it frequents, would probably do it little or no damage if it were speedily rejected. G F. HAMPSON.

THE accompanying insects—apparently Orobatid mites—were found by me in the district of Tallawakelle, Ceylon (alt 4600 ft), under stones and rocks in damp, shady situations. It was only by accident that I became aware of their remarkable weapons of defence—an exceedingly pungent secretion.

About five hours after handling one of these insects I accidentally touched my tongue with my finger Immediately an extraordinarily pungent, galvanic sensation or taste commenced rapidly to spread over my mouth, quickly reaching my throat Rinsing my mouth and gargling with hot water failed to arrest the progress of the sensation, which was accompanied with excessive salivation The unpleasantness lasted for several hours, and then died away without any further consequences. I also unconsciously rubbed my face, at the angle of the eye, with the same finger, after which a rather pleasant warmth spread over that part of my face, and was distinctly perceptible the following morning

I could not for some time trace the cause of this effect I at first put it down to the agency of a fungus that I had been carrying, but a further experiment negatived this idea I afterwards tested the insect, and found it to be the real agent The experiment was repeated at my suggestion, by a medical friend—Dr. R J Drummond—who can testify to the result He described the sensation as somewhat like that produced by the strongest menthol We both noticed that it had a numbing effect upon the mucous membrane of the mouth

It is evident that this property must be a very efficient protection to the insect The rapidity with which the secretion acts would cause it to be very quickly ejected if picked up by either a bird or a lizard—the only enemies that would be likely to attack it E ERNEST GREEN.

Eton, Pundulorja, November

A Suggestion

AS very shortly now NATURE will reach its jubilee volume, I hope you will permit me, as an uninterrupted subscriber for nearly twenty years, to offer a suggestion with regard to that occasion

As the volumes of NATURE contain original contributions, observations, and notes in all branches of science, more varied and valuable than are to be found in any other scientific periodical publication in existence, there is not a worker, in whatever branch he may be engaged, that does not find it necessary to be continually referring to its pages, but, unfortunately, through lack of a general handy index, he discovers what he wants only after the expenditure of a very great deal of time and worry

I write, therefore, not only in my own name, but (by request in a private way) in that of a large number of fellow-workers in the subjects in which I am myself specially interested—biology, palæontology, anthropology, geography—to suggest that you should celebrate the jubilee of NATURE by conferring on your readers the immense boon of a classified index to its contents

During some investigations I was making in 1876 7 I so felt the need of a collected index that I went to the trouble of compiling for myself one, up to that date, classified according to sciences, subdivided again according to the sections of each, which in subsequent work saved me weeks of time and trouble. To my regret, this MS got lost or destroyed, and there is nothing in connection with NATURE that I, and I am certain every other worker, would now hail with greater satisfaction than the announcement that the means of reaching with expedition and precision the treasures at present so deeply buried in your (nearly) fifty priceless volumes, will be ced within our reach with its jubilee volume OLD SUBSCRIBER.

Superstitions of the Shuswaps of British Columbia.

REFERRING to the above, as recorded by Dr George Dawson, F R S , in the Transactions of the Royal Society of Canada, and included in your Notes of last issue, in which attention is called to the belief among the Shuswaps and some other North American races, that small lizards enter the bodies of men, pursuing them, and devouring their hearts, I was at once struck with the almost exact resemblance of this belief to one very generally prevailing in Ireland, as regards common water Newts, which go by the name of Man eaters (pronounced Man-aters) This I can testify to from personal knowledge, but it has been accidentally confirmed by an experiment which I hope I may be pardoned for referring to. Where I reside are three Irish servants, to whom I caused to be shown a drawing of the Water Newt, and with the request that I might be told its

name, and anything ~~k~~ they knew about it One of these, a Galway woman, spea_ng Irish better than English, gave me the name in her langu ge (which I won't attempt to transcribe, for it was a very long one), and also said that the animals were well known to jump down people's throats to their certain destruction C Bushe

Athenæum, December 24.

The Great Ice Age

There is in the Astronomical theory of the Ice Age a point of some importance, not mentioned by Sir Robert Ball in his interesting work on this subject, to which I invite the reader's attention I mean *the slowness with which the difference between the length of summer and that of winter is varying in the neighbourhood of its maximum*

To compute this difference and its mean value, we put

a = the mean distance of the earth from the sun,
e = the eccentricity of the earth's orbit,
ω = the longitude of the perihelion of the earth's orbit,
T = the length of the year in mean solar days,
Δ = the difference between the lengths of the two seasons in mean solar days,
η = the mean value of this difference during the interval between the two dates, corresponding to $\omega = \omega_1$ and $\omega = \omega_2 > \omega_1$

Then, the eccentricity remaining always extremely small, the difference between the areas of the two segments in which the line of the equinoxes divides the earth's orbit, may be put—and with sufficient accuracy,

$$= 2ae \quad 2a \sin \omega = 4a^2 e \sin \omega$$

Hence, we find, by Kepler's first law,

$$\frac{\Delta}{1} = \frac{4a^2 e \sin \omega}{\pi a^2 \sqrt{(1 - e^2)}},$$

and consequently, by neglecting the third and higher powers of e,

$$\Delta = \frac{4\mathrm{T}e \sin \omega}{\pi}$$

Observing that the eccentricity remains sensibly constant for a period of time, which is doubtless to be reckoned by many tens of thousands of years, we obtain, by means of the formula just found,

$$\eta = \frac{4\mathrm{T}e}{\pi}\int_{\omega_1}^{\omega_2} \sin \omega d\omega \quad \int_{\omega_1}^{\omega_2} d\omega$$

$$= \frac{4\mathrm{T}e}{\pi} \frac{\cos \omega_1 - \cos \omega_2}{\omega_2 - \omega_1}$$

Finally, by substituting the numerical values of our constants, we shall have the following formulæ for computing Δ and η —

$$\Delta = 465 e \sin \omega,$$

$$\eta = \frac{465 e (\cos \omega_1 - \cos \omega_2)}{\omega_2 - \omega_1},$$

positive values designating that in the Northern Hemisphere and negative values that in the Southern Hemisphere the summer exceeds the winter.

From the first formula we deduce that, for a given eccentricity, the disparity in the lengths of the seasons shall be as great as possible when the line of the equinoxes is perpendicular to the axis major of the orbit Now, putting e = 0, 071, the maximum eccentricity, the values of Δ and η for a few values of ω are as follows —

ω	Δ	$\omega_2 - \omega_1$	η
°		to	
90	33		
85 or 95	33	95 – 85	33
80 or 100	32½	100 – 80	33
75 or 105	32	105 – 75	32½
70 or 110	31	110 – 70	32
65 or 115	30	115 – 65	32
60 or 120	28	120 – 60	31½
55 or 125	27	125 – 55	31
50 or 130	25	130 – 50	30
45 or 135	23	135 – 45	29½

If we remember that the longitude of the perihelion increases in about twenty-one thousand years from 0° to 360°, then, it will be seen by inspecting these results that, for example, during the interval between the two dates corresponding to ω = 65° and ω = 115°, *i e* during a period of nearly three thousand years, the mean difference between summer and winter will be thirty two days, and that during this period the difference itself will never sink below thirty days N L W A Gravelaar

Deventer, Netherlands, December 17

Aggressive Mimicry

In his last letter Mr Poulton observes that I am one of "four recent writers" who have made use of the collections in the Natural History Museum and the Museum of the Royal College of Surgeons, for the purpose of illustrating the phenomena of mimicry between *Volucella* and *Bombex* This is the case, but I should like to add that the species which I have depicted are not *V bombylans* and *B muscorum* (the questionable resemblance of which in nature, and the erroneous labelling of which in the "show cases," constitute the grounds of Mr Bateson's somewhat "aggressive" criticism on other "recent writers"), but *V bombylans* and *B lapidarius*, where the fact of resemblance can admit of no doubt (' Darwin and After Darwin," p. 329) Indeed, Mr Bateson fully recognizes the close similarity in appearance between these two species, and, as I refrained from giving the hypothetical explanation of it to which he objects, I avoided all the issues which have since been raised in the Nature correspondence

Madeira, December 15 George J Romanes

Artificially Incubated Eggs

I have been repeatedly informed by poultry-growers and market men that hens raised from artificially incubated eggs were much less fertile than those produced in the natural way My information has been derived from persons who did not even know each other It occurs to me that if true it is a curious matter and worthy of some attention

December 10

THE PROPOSED UNIVERSITY FOR LONDON

A general meeting of the Association for Promoting a Professorial University for London was held on Wednesday, December 21, when a report, which we print below, was presented by the Executive Committee We would call the attention of our readers to the penultimate paragraph of this report, which indicates the existence of an agreement, on matters of principle between the Senate of the University of London and the Association

The last general meeting of members of the Association was held on June 14, 1892, when the Executive Committee presented for approval a series of proposals for the organization of a University in London These proposals were adopted as the formal expression of the objects of the Association

Since that meeting the efforts of the Committee have been directed to the furtherance of the principles embodied in the above-mentioned proposals—by endeavouring to obtain the adhesion of literary and scientific men, and of other persons interested in the matter, by organizing a body of evidence to be presented to the Gresham University Commission, and by such other means as have suggested themselves from time to time

Immediately after the last general meeting, Prof. Huxley became a member of the Association, and consented to accept the office of president. Sir Henry Roscoe and the Master of University College, Oxford, consented to become vice presidents; and the first of these gentlemen has since been an active member of the Executive Committee.

The number of members of the Association is now one hundred and fifty

Evidence in support of the principles of the Association has been given before the Gresham University Commission by the following gentlemen.—Prof. Ayrton, Mr F V. Dickins, Prof. G C Foster, Principal Heath, Prof.

Henrici, Prof Huxley, Prof Ray Lankester, Prof Henry Nettleship, Prof Pearson, Sir H Roscoe, Prof. Rucker, Dr Russell, Prof T E. Thorpe, Prof Unwin, Dr Waller, Dr Windle, Prof Weldon.

During the month of November the Committee were informed that a Committee of the Senate of London University had drawn up a series of resolutions, to be submitted to the Royal Commission Your Committee therefore requested the Vice-Chancellor to allow its members to address the Committee of the University Senate in support of the proposals of the Association The Vice Chancellor replied by inviting the Executive Committee of the Association to attend a meeting of the University Committee on Wednesday, December 7 At this meeting the objects of the Association were explained by the President, Sir Henry Roscoe, and Prof Weldon, and the Vice-Chancellor in reply made an important statement, to the effect that the resolutions which were put forward by the Committee of the Senate were intended to be understood in such a manner as to render them perfectly consistent with the programme of the Association. The resolutions proposed by the University Committee, and since adopted by the whole Senate, are as follows —

The Senate having reason to believe that a distinct expression of opinion may be useful to the Commissioners at the present stage of the inquiry, desire to recall to their attention the fact that during last year the Senate approved a Scheme for a Reconstitution of the University which provided for the constitution of Faculties consisting of teachers and of Boards of Studies in each Faculty, and for the election of members of the Senate by the Faculties, and that the Scheme further proposed to confer on the University power to hold real property and to accept grants, gifts, devises, and legacies for the purposes of the University, including the establishment of Professorships and Scholarships, whether attached or not to any particular College, and the furtherance of regular liberal education and of original research

The Senate now desire to state that, if in accordance with the decision of the Commissioners, the Senate is prepared, in order to promote the efficiency of the University, and with a view to its reorganization as a Teaching University in and for London, without curtailment of the functions which it now discharges—

(a) To establish and incorporate with the University Faculties in Arts, Science, Laws, and Medicine, and Boards of Studies acting thereunder

(b) To provide for the incorporation with the University of Teaching Institutions of the higher rank

(c) To utilize, with their consent, existing organizations for higher culture, and subject to such utilization to institute and maintain Professorships and Lectureships, whether for academical or other purposes, and generally to assume such functions as may be required for the furtherance and superintendence of a regular liberal education, and for the promotion of original research

(d) To accept and administer fees and such other funds, public or private, as may be necessary, and may be granted or given for the purposes of the reorganized University

(e) To provide for the adequate representation of the Professoriate on the Senate.

The Committee regret that Prof. Pearson, whose energy and enthusiasm have been of such essential service to the Association, has felt obliged to retire from the office of Secretary His place has been taken by Prof. Weldon

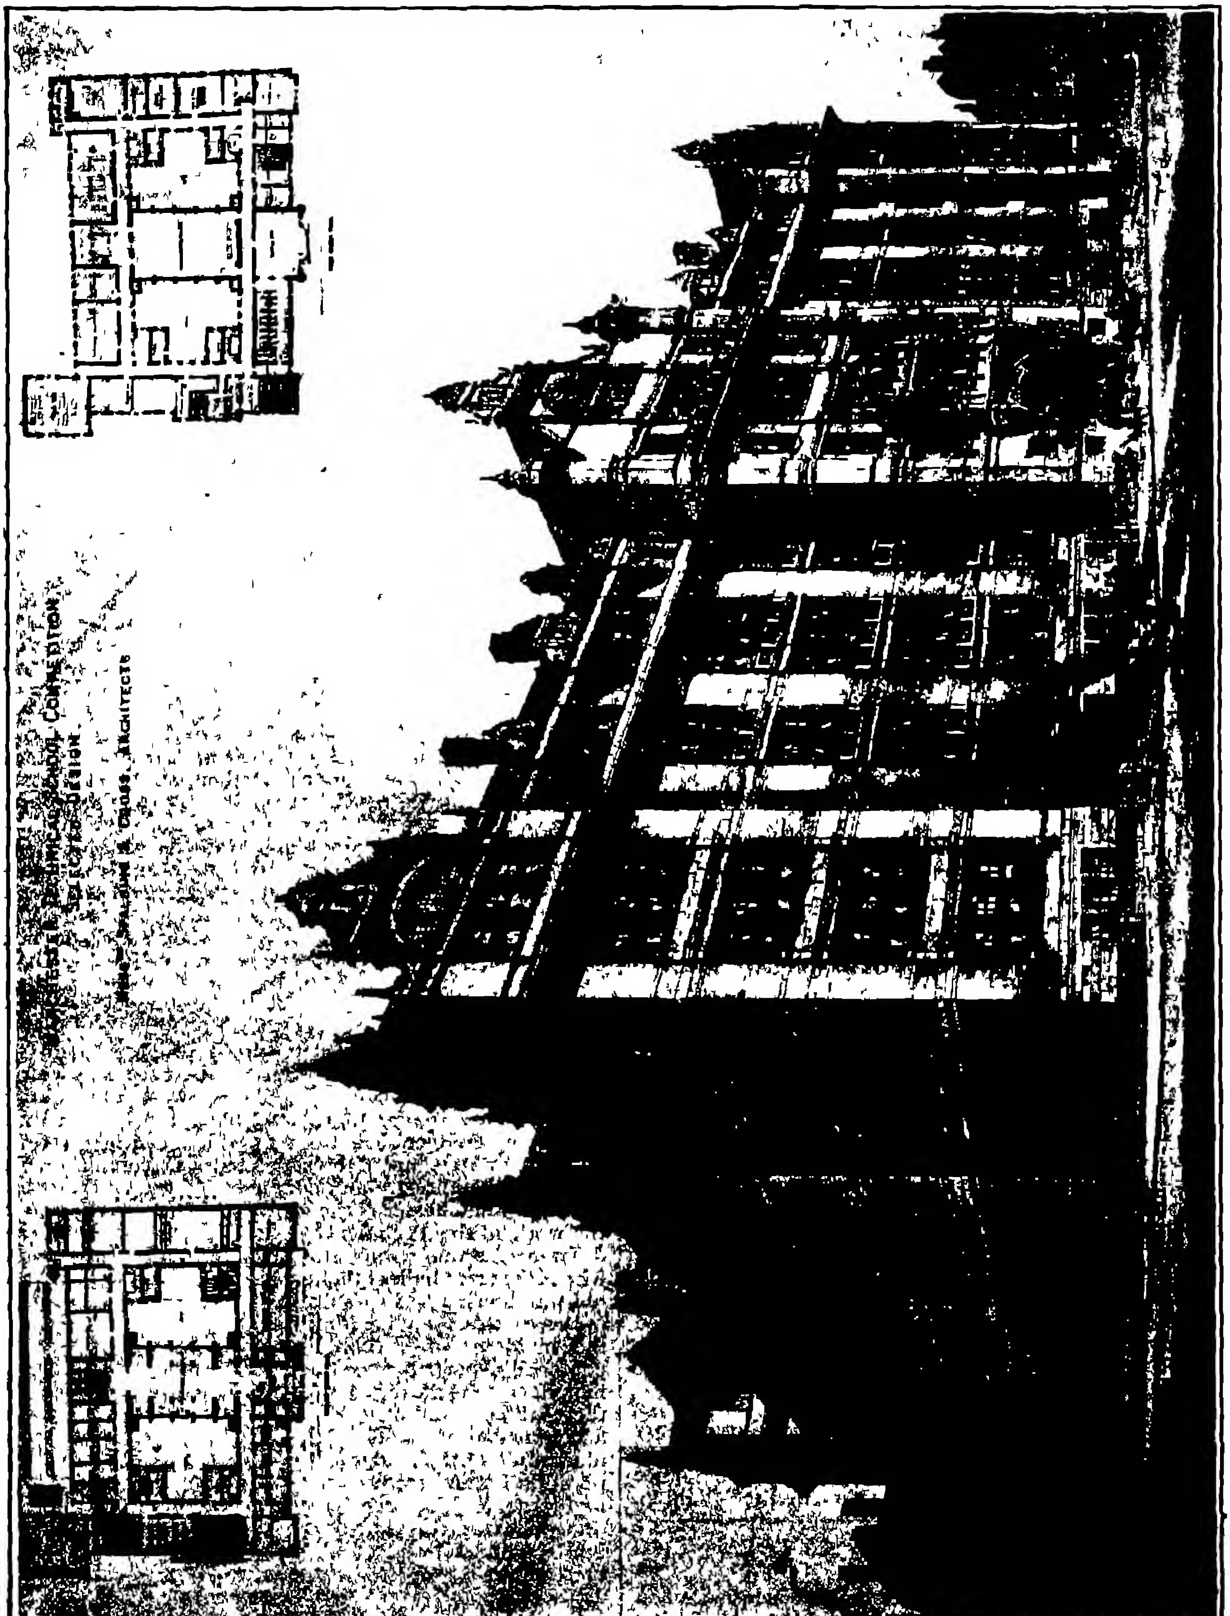
THE MANCHESTER MUNICIPAL TECHNICAL SCHOOL.

IN his interesting address on technical education, when distributing the prizes of the Manchester Municipal Technical School, on the 19th inst, Mr. Balfour pointed out that the occasion was an important one, not only in the history of technical instruction in Manchester, in the history of the Corporation of that city, but also in the commercial and manufacturing history of Manchester itself, since this was the first public occasion of the distribution of prizes to the scholars of the Technical School and the School of Art since these schools were taken over by the municipality, and supported out of the public funds of the city The fact that the Corporation of the northern metropolis has taken possession of the School of Art and of the flourishing Technical School, founded a few years ago on the site of the old Mechanics' Institution, is one which may well claim the attention of the leading statesmen of our time, and Mr Balfour has done good service to this great educational movement by thus placing prominently before the country the part which our municipal authorities are now playing in the matter Fully alive to the revolution which these changes are bringing about in our educational system, Mr Balfour, speaking to the teachers and students, insisted that there is now thrown upon them something more than personal responsibility, something more than the desire for self-advancement They are concerned, he said, in a national work, and ought to look at it from a national point of view, and it is this public aspect of the question which justifies and more than justifies the Corporation for having taken up this great work and for having created the greatest technical school at present existing in England, but which, great as it is, is still in its infancy, and will yet show developments which will astonish those who are now devoting their time to it in so public-spirited a fashion.

Then spoke Mr Councillor Hoy, the chairman of the Technical Education Committee of the Corporation, and in thanking Mr Balfour for his "thoughtful and charming address" added that it was only nine months since these schools were handed over to the Corporation, that they had to master the whole machinery of the education, to arrange all the details of the transfer, but that in addition they had plunged right away into the necessary steps for erecting a new and enlarged school

So it is evident that the men of Manchester do not allow the grass to grow under their feet They know that the business they have undertaken is a big one, and they, like good business men, are prepared boldly to meet the necessities of their position. How boldly and how completely they propose to do so will be seen when we learn what are the proposals which they have made for carrying on their work, for making the necessary preparations, for giving the highest and most complete technical training which can be given in all those matters upon the satisfactory accomplishment of which, the industry and commerce of the vast district of which Manchester is the centre depends At present the work of the Technical School is carried on in three different buildings, one the old Mechanics Institution where the great bulk of the teaching is done, another in an old warehouse fitted to suit the wants, as far as may be, of the electrical engineering department, and a third in the buildings of a school where a very completely-equipped department for the scientific study of the cotton manufacture is arranged Needless to say that none of these three buildings provide sufficient or adequate accommodation for the proper practical teaching and illustration of their subjects, and no sooner had the Corporation Committee become acquainted with what they had to do, and the means placed at their disposal for doing it, than they made up their minds that a new building must be erected fully representative of the present needs, and with room, if possible, for future developments

But before committing themselves to plans or estimates, this committee wisely determined to see with their own



eyes what was doing and had been done elsewhere They visited the English schools, such as they are, and, more important, they went abroad and inspected the well-known technical schools on the continent, and on their return they issued an interesting report containing not only an account of what they saw and learnt, but the conclusions they drew as to how far their Manchester school should be modelled on foreign lines This journey of inspection gave the members of the committee a new and enlarged view of their duties, and they returned home with the determination that if they could not approach the size of such buildings as the Zurich Polytechnicum or the Technical High School of Charlottenburg, at any rate they would put up a school which should be as complete in its parts as any similar institution abroad and capable of doing for their centre work equally useful and of exerting an equally beneficial influence on their population as any of the foreign schools Some captious critics were loud in their condemnation of such a way of spending public money as that of sending a number of Manchester men on an educational tour abroad In fact, no money could be or has been more judiciously or more economically spent Without a knowledge from personal observation of what is doing elsewhere, these gentlemen could not possibly have carried out their business to a successful issue, with such a knowledge they can and will do it

Fortunately for Manchester, the necessity for technical training of the people was long ago preached by one of her most distinguished sons, the late Sir Joseph Whitworth, and his legatees, knowing his views, presented a site for the school of 5000 square yards, situated in the centre of the city, and well placed as regards light and air On this site the Corporation have decided to build a spacious, not to say magnificent, school, a perspective view of which is found on the opposite page The whole of the site, including 770 yards in addition given by the Corporation, is to be covered by buildings, and in it ample accommodation will be found for the work carried on in the present temporary premises This will include engineering, mechanical, electrical, civil and sanitary, the chemical industries, the cotton manufacture, spinning and weaving, the building trades, dyeing and calico printing, metallurgy, letterpress and lithographic printing, and other minor industries, industrial art and design, and the subjects classed under the heads of commercial and economical instruction. And in addition to these proper accommodation for the teaching of the pure sciences, mathematics, foreign languages, to say nothing of manual instruction and gymnastics All these matters require means of giving practical instruction, not only lecture rooms, but laboratories, workshops, and museums, so the problem of satisfying all their needs is a complicated one, but one which the committee are determined to do their best to carry out The size of the proposed building called forth a large number of competing designs from some of the first architects of the day, and the first premium was awarded by the Committee, assisted by Mr Waterhouse, R.A, to Messrs Spalding and Cross, of London Their design is in Renaissance style of the early French period, and the internal arrangements are made with the view of giving as much light as possible The material is red brick with terra cotta facings, it is roofed with green Whitland Abbey slates. The building will be fireproof throughout, and the flooring covered with wood blocks, except in the case of the dyehouse and laboratories, where impervious paving is needed One great desideratum in such a building is proper ventilation; this will be arranged on the plenum or plus pressure system, the air being pumped throughout the building by fans worked by electricity, and the lighting will also be electrical. The building is six stories high, none of the rooms will be lower than 15 feet clear, and averaging from 25 to 30 feet in depth. The class rooms, lecture theatres, drawing and designing offices, laboratories, library, workshops and administrative department, as well as the students' and lecturers' rooms, are all lighted from the face of the building with wide continuous corridors all round each floor, lit from internal areas, and each department will be as far as possible separate and self-contained The total available floor-space exceeds 150,000 square feet exclusive of the corridors The main entrance hall is 85 by 50 feet, and it is to be utilized as an industrial museum, on the first floor is a public lecture hall 30 feet high, and of the above dimensions On the third floor is the chemical laboratory arranged for 80 working benches Two independent staircases, as well as a spacious passenger lift give access to the different floors, and extra exits are provided in case of fire The basement, which is only seven feet below the ground line, is to be fitted with heavy machinery and other apparatus used in industrial operations on a considerable scale Here we find the electrical and mechanical workshops and testing machinery, rooms for purposes in which stability is necessary, experimental steam engine, dynamo, and secondary battery rooms, spinning and weaving machinery for cotton and silk, rooms for bleaching, dyeing, and finishing; plumbers', bricksetters', and masons' workshops, shops for repairs, and construction of new apparatus, &c The upper stories contain the laboratories, general and special, lecture rooms, drawing offices, gymnasium, library, and students' reading and common rooms

The following is the space allotted on the various floors for the several departments —

		Sq feet.
1	Administration, Museum, Lecture Hall, Library, Reading Room, Gymnasium, and other offices	26 837
2	Mechanical Engineering	18,266
3	Applied Physics and Electrical Engineering	13,666
4	Textile Trades	19,211
5	Applied Chemistry, Dyeing, &c, Metallurgy	29,232
6	Building Trades	10,922
7	Letterpress and Lithographic Printing	2,798
8	Industrial Design	13,453
9	Commercial Subjects	11,844
10.	Domestic Economy Subjects	6,461
	Total	152,690

As if to indicate the determination to make the utmost of their building, the Committee have asked Sir Howard Grubb to design a small astronomical and meteorological observatory on the roof! This in the centre of smoky Manchester, but experts say that even here much useful work can be done.

The estimated cost of the building, including fittings, apparatus, and machinery is about £125 000; towards this sum the Committee have available £14,000 balance of profit from the Jubilee Exhibition; £5000 promised by the Whitworth trustees; and the property belonging to the old schools estimated at £31,000. The remainder of the sum, about £75,000, the Corporation will borrow for a period of thirty years on the security of the 1d rate This great school will be governed by a Committee of thirty-six persons, twenty-four of whom are members of the City Council, twelve being chosen from the public interested in the progress of Industrial and Commercial Education

Enough has been said to give the reader an idea of the scale and completeness of the proposed Municipal School To work this properly will cost nearly £10,000 per annum. The fees will be low, but nevertheless will bring in a goodly sum, and the funds available from the Local Taxation (Customs and Excise) Act of 1890—commonly termed the beer money—will provide the remainder Such a school, holding as it will do an intermediate position, between the Board Schools on the one hand, and highest University Education as given in the Owens

College on the other, cannot fail to exert a most important influence on the future development of trade and manufactures in Lancashire. What Manchester is doing in this magnificent way, other towns, notably Birmingham, Salford, Stockport, Oldham, Bolton, and others, are also doing, it is true on a smaller scale, but still in a manner sufficient for their needs. How long will it be before London moves? H. E. ROSCOE

THE MONT BLANC OBSERVATORY[1]

THE project of establishing a meteorological and astronomical observatory on the summit of Mont Blanc has, under the care of M. J. Janssen, of the Meudon Observatory, made considerable progress during this year's summer months. It has been decided to use the snow itself as a foundation on which to rest the building. That this can be done with security was shown by some experiments carried out at Meudon last winter. A miniature mountain was made of snow pressed to the same density as that which is found on Mont Blanc at a depth of one or two metres below the surface. This being

made level at the top, discs of lead 35 cm. in diameter, and weighing each about 30 kgr., were placed on the snow, one upon the other. After twelve of these had been piled up, with an aggregate weight of 360 kgr., they were removed and the depth of the impression measured. It was not more then 7 or 8 mm. Thus a structure measuring 10 m. by 5 m. might safely weigh 187,000 kgr. without sinking into the snow more than a few centimetres.

The summit of Mont Blanc is formed by a very narrow edge of rock 100 m. long, running from west to east, and covered by snow which is thicker on the French than on the Italian side. The level of this snow has not shown any important oscillations throughout a number of years. To obviate the disturbing effects of the storms which frequently rage round the summit, the building is constructed in the shape of a truncated pyramid, the lower floor being sunk into the snow. The rectangular base measures 10 m. by 5 m. The upper floor, which will be devoted to the observations, is covered with a flat roof, towards which ascent is made by a spiral staircase leading from the basement upwards through the whole building, and above the flat roof to a small platform destined for meteorological observations.

The whole observatory has double walls to protect the observers against the cold. The windows and doors are also double, and provided on the outside with shutters closing hermetically. The floor is made of double planks, and furnished with trap-doors giving access to the snow supporting the observatory, and to the screw-jacks placed in position for adjusting the level of the building in case the snow should yield. The building will be provided with heating apparatus and all the furniture necessary to make habitation at such an altitude possible.

Up to the present the observatory has been transported in parts to Chamounix. On the Grands-Mulets a cottage has been erected for the use of the workmen and for storing the things destined for the observatory.

On the Grand Rocher Rouge another cottage has been built, only 300 m. below the summit, in which the workers and observers can, if necessary, take refuge. Three-quarters of the materials for the observatory have been transported to the Grands-Mulets (3000 m.) and the rest to the Rocher Rouge (4500 m.).

Next year the erection on the summit will be carried out. An astronomical dome, which is to complete the observatory, will also be taken in hand. The work done up to now has been carried out under great difficulties, owing to the fact that everything had to be carried by hand. But no accident has, so far, marred the success.

Dr. Capus, who accompanied M. Bonvalot in his well-known expedition to the Pamir, has promised his assistance for certain observations. But the observatory will be international, and open to all observers who wish to work there. E. E. F. d'A.

M. PASTEUR'S SEVENTIETH BIRTHDAY

FRENCHMEN may be cordially congratulated on the enthusiasm with which the seventieth birthday of M. Pasteur was celebrated on Tuesday. It afforded a most striking illustration of the way in which they appreciate the services rendered by men of science. But the celebration was not, of course, one in which only the countrymen of M. Pasteur were interested; representatives of science from many different parts of the world were present to do honour to the illustrious investigator.

The ceremony took place in the great amphitheatre of the Sorbonne, which was crowded by a brilliant assembly including many of the foremost men of the day, not merely in science but in politics and literature. M. Carnot was present, and among those who supported him was M. Dupuy, the Minister of Public Instruction. M. Pasteur entered the amphitheatre leaning upon the arm of his son and upon that of the President of the Republic. All who were present rose to their feet and greeted the hero of the day with loud cheers. M. Pasteur, who was much affected by this reception, took his place beside his colleagues of the Institute and a row of Ambassadors and Ministers.

The proceedings were opened by M. Bertrand, perpetual secretary of the Academy of Science, who acted as chairman. At his request an address was delivered by the Minister of Public Instruction, who spoke eloquently of the great qualities displayed by M. Pasteur during his splendid career, and of the benefits conferred on man-

[1] Janssen, Comptes rendus, November 28.

kind by his labours. After the Minister came M d'Abbadie, the President of the Academy, who, expressing the congratulations of the Institute, presented to M Pasteur the large gold medal which had been struck in commemoration of the day The medal bears on the obverse a likeness of M Pasteur, while on the reverse is the following inscription "To Pasteur, on his seventieth birthday, from grateful science and humanity, Dec 27, 1892" M Bertrand also spoke, and both his speech and that of M d'Abbadie were cordially applauded. Sir Joseph Lister, one of the delegates sent by the Royal Society, was warmly greeted He read in French the following address —

"M Pasteur, the great honour has been accorded me of offering you the homage of medicine and surgery There is certainly not in the entire world a single person to whom medical science is more indebted than to you Your researches on fermentation have thrown a flood of light which has illuminated the gloomy shadows of surgery, and changed the treatment of wounds from a matter of doubtful and too often disastrous empiricism into a scientific art, certain and beneficent Owing to you, surgery has undergone a complete revolution It has been stripped of its terrors, and its efficiency has been almost unlimitedly enlarged But medicine owes as much to your profound and philosophic studies as does surgery You have raised the veil which had for centuries covered infectious diseases You have discovered and proved their microbic nature, and, thanks to your initiative, and in many cases to your own special labour, there are already a host of these destructive disorders of which we now completely know the causes 'Felix qui potuit rerum cognoscere causas' This knowledge has already perfected in a surprising way the diagnosis of certain plagues of the human race, and has marked out the course which must be followed in their prophylactic and curative treatment In this way your fine discoveries of the attenuation and reinforcement of virus and of preventive inoculations serve, and will serve as a lode-star As a brilliant illustration, I may note your studies of rabies. Their originality was so striking that, with the exception of certain ignorant people, everybody now recognizes the greatness of that which you have accomplished against this terrible malady You have furnished a diagnosis which immediately dispels the anguish of uncertainty which formerly haunted him who had been bitten by a dog mistakenly supposed to be suffering from rabies If this were your only claim on humanity, you would deserve its eternal gratitude But, by your marvellous system of inoculation against rabies, you have discovered how to follow the poison after its entry into the system, and to conquer it there M Pasteur, infectious maladies constitute, as you know, the great majority of the maladies which afflict the human race You can therefore understand that medicine and surgery are eager on this great occasion to offer you the profound homage of their admiration and of their gratitude"

Among other addresses was a striking speech by the Mayor of Dôle, M Pasteur's birthplace After the presentation of gifts by foreign delegates, M Pasteur rose and spoke a few words, which, according to the Paris correspondent of the *Times*, were "broken by sobs" A speech was then read for him by his son. In this speech, as reported in the *Times*, M Pasteur said, after referring to M Carnot's presence —"In the midst of this brilliant scene my first thought turns with melancholy to the recollection of so many scientific men who have known nothing but trials. In the past they had to struggle against the prejudices which stifled their ideas. These prejudices overcome, they encountered obstacles and difficulties of all kinds. Even a few years ago, before the public authorities and the Municipal Council had provided science with splendid buildings, a man whom I loved and admired, Claude Bernard, had for a laboratory, a few steps from here nothing but a low damp cellar Perhaps it was there he was struck by the malady which carried him off When I heard of the reception intended for me, his memory rose first of all to my mind I hail that great memory It seems that you have desired by an ingenious and delicate idea to make my entire life pass before my eyes One of my Jura countrymen, the Mayor of Dôle, has brought me a photograph of the humble house where my father and mother lived under such difficulties The presence of all the pupils of the Polytechnic School reminds me of the glowing enthusiasm with which I first entered on the pursuit of science The representatives of the Faculty of Lille recall for me my first studies on crystallography and fermentations, which opened quite a new world to me What hopes filled me when I discovered that there were laws behind so many obscure phenomena! You have witnessed, my dear colleagues, by what a series of deductions I have been enabled as a disciple of the experimental method to arrive at physiological results If I have sometimes disturbed our academies by somewhat livelier discussions, it is because I was passionately defending truth

"You, lastly, delegates of foreign nations, who have come so far to give France a proof of sympathy, you afford me the most profound gratification which can be experienced by a man who invincibly believes that science and peace will triumph over ignorance and war, that peoples come to an agreement not to destroy, but to build up, and that the future will belong to those who have done most for suffering humanity I appeal to you, my dear Lister, and to you all, illustrious representatives of science, medicine, and surgery Young men, trust those certain and powerful methods, only the first secrets of which we yet know And all of you, whatever your career, do not allow yourselves to be infected by vilifying and barren scepticism, do not allow yourselves to be discouraged by the gloom of certain hours which pass over a nation Live in the serene peace of laboratories and libraries Consider first of all, 'What have I done for my education?' and then, as you advance, 'What have I done for my country?' until the moment when you will perhaps have the immense happiness of thinking that you have contributed in some way to the progress and welfare of mankind But whether your efforts are more or less favoured in life you must, on nearing the grand goal, be entitled to say, 'I have done what I could' I express to you my profound emotion and warm gratitude Just as, on the back of this medal, the great artist Roty has concealed under roses the date of birth which weighs so heavily on my life, so you have desired, my dear colleagues, to give my old age the spectacle which could most delight it—that of these eager and loving young men"

This closed the ceremony M Carnot, before quitting the building, walked over to M Pasteur and embraced him The celebration was one of which France has good reason to be proud, and Englishmen may well regret that such a demonstration, common to governors and governed, would in this country be impossible

NOTES

THIS week the American Society of Naturalists has been holding at Princeton, N.J, its eleventh annual meeting, the chair being occupied by Prof Henry F Osborn, Columbia College, New York On Tuesday a lecture was to be delivered by Dr. C Hart Merriam on the Diak Valley Expedition (illustrated) On Wednesday, after the transaction of general business, the following reports on marine biological laboratories were to be read:—The Sea Isle Laboratory, by Prof J A Rider, University of Pennsylvania, a marine station in Jamaica, by

Prof E A Andrews, Johns Hopkins University, the marine laboratories of Europe, by Dr D Bashford Dean, Columbia College, and the outlook for a marine observatory at Woods Holl, by Prof C O Whitman, University of Chicago In the evening the annual dinner of the society was to be held, and the president's address was to be delivered The following are the principal arrangements for to-day (Thursday) —A paper is to be read by Dr C W. Stiles, Agricultural Bureau, Washington, on the endowment of the American table at Naples, and reports are to be read on botanical explorations in Florida, by Prof. W P Wilson, University of Pennsylvania, the summer work of the U S Fish Commission Schooner *Grampus*, by Prof William Libbey, Junr, Princeton College, and expeditions of the American Museum of Natural History into New Mexico, Wyoming, and Dakota, by Dr J L Wortman, American Museum Natural History Then will come the annual discussion, the subject being, What were the former areas and relations of the American Continent, as determined by faunal and floral distribution? The following papers will be read — Introduction, and evidences from past and present distribution of mammals, by Prof W B Scott, Princeton College, evidence from past and present distribution of reptiles, by Dr George Baur, University of Chicago, evidence from the distribution of birds, by Prof J A Allen, American Museum of Natural History, and evidence from the distribution of plants, by Dr N L Britton, Columbia College Special meetings have been held by the American Societies of Anatomists, Morphologists, and Physiologists

WE learn, from the *Oesterreichische Botanische Zeitschrift*, of the death, at Vienna, of the veteran palæontologist, Dr D Stur, Director of the Imperial Geological Institute in that city, and author of several finely illustrated works on palæo-phytology

DR VOLKENS, Privatdocent at the University of Berlin, and Dr Lent are about to start for East Africa, where they propose to carry on scientific investigations The former has received a grant from the Prussian Academy of Sciences, and will devote himself especially to botanical study Dr. Lent has received aid from the German Colonial Society, and will give especial attention to geology

DR F BUCHANAN WHITE has presented his fine collection of lepidoptera to the Museum of the Perthshire Society of Natural Science, which is in process of being greatly enlarged The collection contains twelve thousand specimens, which have been collected by Dr White in many parts of Europe, though mainly in Great Britain and largely in Perthshire Many are type specimens, which have been described and figured by the collector in his numerous descriptive papers, and several represent species that have now become extinct

DURING the latter part of last week an area of low pressure lay to the south-westward of our islands, causing south-easterly gales on our western coasts. This disturbance, however, although it advanced from off the Atlantic, remained comparatively stationary for two or three days, during which time the weather continued fine and dry over England At the close of the week the low pressure area gave place to an area of high barometer readings, which gradually spread over the United Kingdom from the continent, bringing dry weather and severe frost, with fog in many places The thermometer in the shade fell to 9° in Leicestershire, and to 17° in London in the night of the 26th, and in many places the day temperature continued much below the freezing point during both Monday and Tuesday At this time the anticyclone had become thoroughly established, and the area of cold was increasing both in size and intensity, although the conditions in the extreme north indicated a possible change The *Weekly Weather Report* for the period ending the 24th inst shows that temperature was above the mean in all districts, being as much as 5° or 6° over Ireland During the early part of the week the night minima were very high for the time of year Rainfall was less than the mean in all districts, the deficiency being most considerable in Scotland and in the south-west of England Bright sunshine was also very deficient, in Scotland and Ireland there was only from 2 to 3 per cent of the possible amount

THE Weather Bureau of the U.S Department of Agriculture has published some valuable "Observations and Experiments on the Fluctuations in the Level and Rate of Movement of Ground-water on the Wisconsin Agricultural Experiment Station Farm, and at Whitewater, Wisconsin," by Franklin H King The author holds that a careful and detailed study of the movements of ground-water ought to supply very important knowledge bearing upon the contamination of drinking waters and the spreading of certain classes of contagious diseases, and thus help to place the water supply for both urban and rural purposes under better sanitary conditions Every advance which is made towards the increase of yield per acre necessarily means an increased demand for water, so that market gardeners even in Wisconsin and Illinois, where both the annual and summer rainfall is relatively large, are turning their attention, Mr King says, to the question as to the best means for providing irrigation A rapid and economical advance in this direction demands, he thinks, a much more thorough knowledge of the movements of underground water than we at present possess He also urges that in the utilization of natural subirrigation, and in the reclaiming of swamp lands for agricultural purposes, there is imminent need for new knowledge in the same direction Mr King does not overrate the importance of his own researches He regards them simply as preliminary studies

H HABENICHT, of Gotha, has contributed a paper to *Ausland* (No 49) on the frequency of icebergs in the Gulf Stream and variations of climate, based upon the reports of icebergs published since 1883 in the pilot charts of the North Atlantic Ocean. He gives a table showing the number of bergs reported in each year in the Gulf Stream, with a summary of the temperature conditions experienced in Europe during each of the four seasons. The number of icebergs varied considerably in different years, from ten in the year 1888 to 674 in the year 1890 The table shows some unmistakable coincidences between the frequency of the bergs and the character of subsequent weather about six months afterwards The extremely low minimum of iceberg frequency in 1888 was followed by the warmest year of the series, all the seasons of 1889 were warm over Europe There was another less marked minimum of icebergs in 1889, and this was followed by a relatively warm year in 1890 The remarkable maximum of bergs in 1890 was followed in 1891 by the coldest winter that had occurred for twenty years, and the cold winter was followed by an abnormally cold spring and summer. The table also shows that the coincidences are more marked with iceberg maxima than with minima. Two of the latter in two successive years were followed by only one warm summer, while in the case of the maxima the decrease of temperature occurred in the next year.

MR D T MACDOUGAL contributes to *Science*, December 2, an interesting account of some explorations recently made by a botanical expedition in Idaho. The work of the expedition was planned by Dr G Z. Vasey, chief botanist of the U S. Department of Agriculture. The results are summarised thus:— The basins of Lakes Coeur d'Alene and Pend d'Oreille and of the Clearwater and Palouse rivers were explored, the botanically unknown area in Central Idaho now being limited on the south by the Snake River basin, on the west by the Snake River

and the basin explored. About 25,000 specimens of dried plants were collected, representing nearly 1000 species, many of them undescribed forms. Valuable facts concerning general distribution of plants were obtained, since the area explored is one where the Rocky Mountain flora meets and intermingles with the Pacific coast flora in a very interesting manner, while the opportunity afforded by numerous mountain slopes for the furthering of some problems of vertical distribution was not neglected.

AN important paper on fossil mammals of the Wahsatch and Wind River Beds, by H. F. Osborn and J. L. Wortman, has been issued as a bulletin by the American Museum of Natural History, and has also been published separately. It includes a plate and eighteen figures in the text, and is devoted principally to a description of a collection made by Dr. Wortman during the summer of 1891. The authors claim that many new facts of great interest are brought out by the material in the collection. In a preliminary note it is stated that the department of mammalian palæontology in the American Museum of Natural History was established in May, 1891, and that the purpose of the trustees is to procure a representative collection of the American fossil mammals from the successive geological horizons of the West for purposes of exhibition, study and publication. The staff consists of Prof. H. F. Osborn, of Columbia College, Curator, and of Dr. J. L. Wortman, assistant in Palæontology. Mr. Charles Earle and Mr. O. A. Peterson are also engaged as assistants, and Mr. Rudolph Weber as draughtsman. The collections are to be made readily accessible to students, and exhibited as rapidly as they can be put together and mounted. A list of such duplicate specimens as are available for purposes of exchange is to be prepared. A series of casts of the best preserved types is also in preparation for exchange.

LAST week we printed an account of the ceremonies connected with the Tercentenary of Galileo at Padua. In addition to what was then stated we may say that after Prof. Favaro's oration the delegates were invited to present the addresses of which they were the bearers, whereupon, the English delegation having by lot been placed first in order of precedence, at the request of his colleagues, Profs. Darwin and Stone of Cambridge and Oxford, Sir Joseph Fayrer spoke first, on presenting the addresses of the Royal College of Physicians of London and the University of Edinburgh, with which he was entrusted. He spoke in Italian to the following effect:—

"Profondamente commosso all'onore accordatomi dal Reale Collegio dei Medici di Londra, ed anche dall Università di Edinburgo, nel nominarmi il loro delegato, io mi presento davanti a questa insegne adunanza, per far onore alla memoria di uno dei più grandi uomini e dei più illustri sapienti del mondo, e per render omaggio da parte del detto Collegio, così bene come dell' illustre centro di scienza e di filosofia in Scozia, all' inclito scienzato, nonche a felicitare di cuore colla massima riverenza, questo antico seggio di scienza e di filosofia in così lieta e fausta occasione, nella quale si commemorano le scoperte gloriose del celebre e rinomato filosofo, col nome del quale e intimamente collegata la sua storia passata ed anche la sua rinomanza attuale. La scienza di tutto il mondo è senza dubbio in questo luogo ora rappresentata. Da ogni parte sono venuti messaggi di simpatia, ma da nessuno forse, con maggiore premura e zelo che dei compatrioti di Harvey e Newton. Questi, impugnando la facciola caduta dalla mano morta di Galileo, la innalzò e la sostenne per illuminare le tenebre e dischiarare di vera luce i luoghi finallora oscuri anche al gran filosofo stesso, l'altro avendo terminato i suoi studi ed essendo laureato in questa università, divenne dipoi, come socio del Collegio di Londra, famoso per le sue scoperte sulla circolazione del sangue. I suoi studi anatomici che fece a Padova svilupparono in lui quel genio al quale il mondo intero è debitore. Signori miei, non è solo allo scopritore del termometro, e, come si può dire, all' inventore del telescopio; non è neppure all' astronomo famoso che ha stabilito il sistema eliocentrico, ed ha quasi anticipato le scoperte di Kepler, e che ha dimostrato i satelliti di Giove, le fasi del pianeta Venere, i movimenti diurni e mensili della luna e le macchie solari, non è infine all' autore del 'Saggiatore,' del 'Sidereus Nuncius' e del 'Dialogo dei due Massimi sistemi del Mondo,'—ma e piuttosto al fondatore della filosofia sperimentale che noi rendiamo adesso omaggio ed onore. Egli, osando, pensare ed investigari da se stesso, rigettando gli assiomi degli antichi sistemi di filosofia, anche quello di Aristotile stesso, e rifiutando gl' insegnamenti della teologia dogmatica, stabilì il sistema del libero esame, affermando che la scoperta della verità dev' essere il primo motivo, e che si deve cercarla per via di sperimenti e non sull' altrui autorità, e che la verità è unica, tanto in respetto alle scienze divine come alle umane. Ardisco dire che nessun migliore tributo si può fare al gran maestro adesso commemorato, che questa riconoscenza festiva dopo trecento anni, dell' assiduo e instancabile lavoro che ha rovesciato non soltanto il sistema Tolomaico, ma ha dato un nuovo impulso vitale ad ogni ricerca scientifica e filosofica. Signori, con queste poche parole ho tentato d'esprimere i sentimenti dell' illustre Collegio e dell' inclita Università dei quali io sono il modesto interprete, e ho l'onore di sommettere queste indirizzi, e con esse, i voti più sinceri dei miei colleghi per la prosperità futura di questa venerabile Università, la quale, molto avanti a Galileo è stata un primo centro della vita intellettuale in Europa, e che anche adesso e famosa per la sua propria eccellenza e pei suoi rapporti col gran savio di cui si può dire, come ha detto Dante di Aristotile

'Tutti l'ammiron, tutti onor gli fanno.'"

PROF. DARWIN of Cambridge followed Sir Joseph Fayrer with an interesting and eloquent address, also in Italian. He was succeeded by other delegates. We may note that every attention was shown to the foreign delegates, and the great success of the commemoration was courteously assigned by the University authorities in large measure to the sympathy and interest evinced by other nations. It is satisfactory that no inconsiderable share of this was attributed to the English; their addresses being delivered in Italian evidently afforded much pleasure.

THE *Mediterranean Naturalist*, noting the fact that new and spacious buildings are about to take the place of the old biological station at Cette, expresses regret that no institution of this kind has yet been established in connection with the Maltese Islands. It points out that the marine fauna and flora of Maltese waters offer themselves as a rich and practically untouched field of research, the careful working out of which would be attended with scientific and economic results of the greatest importance.

THE same journal mentions that a petition is to be presented to the Governor of Malta praying that the Maltese fisheries may be more efficiently protected. At present considerable latitude is allowed both as regards the methods practised and as regards the times at which the fishing is carried on. "This," says our contemporary, "is not as it should be. No other food supply can take the place of fish, and the fisheries of the islands under adequate protection and judicious management will always be an unfailing and increasing source of wealth."

THE Department of Public Instruction in New South Wales has published in its Technical Education Series (No. 10) the first part of what promises to be a most valuable "Bibliography of Australian Economic Botany," by J. H. Maiden, curator of the Technological Museum, Sydney. Much information on the properties and uses of Australian plants, and on the products obtained from them is embodied in books of travel, in exhibition literature, pamphlets, proceedings of learned societies, professional journals, and newspapers. It is the author's object to render this scattered information convenient for reference.

A GERMAN translation, by Count Goertz Wrisberg, of Dr. W. Fream's "Elements of Agriculture," has been published by

Paul Parey, of Berlin, under the title of "Landwirtschaft in England"

THE current number of Wundt's *Philosophische Studien* contains two experimental articles—both dealing with problems of psychological optics The first (A Kirschmann, "Beitraege zur Kenntniss der Farbenblindheit") gives an account of a number of interesting cases of colour blindness, together with criticisms of existing theories A unique case is that of an inherited, unilateral (left) blindness to the qualities violet, green and yellow In the second (E B Titchener, "Ueber binoculare Wirkungen monocularer Reize") an attempt is made to show that stimulation of one retina is followed by an excitation process in the other The psychophysical results are supported by recent physiological discovery

THE following are the arrangements at the Royal Institution for the Friday evening meetings before Easter, 1893 —Friday, January 20, Prof Dewar, F R S, liquid atmospheric air, Friday, January 27, Francis Galton, F R S, the just-perceptible difference, Friday, February 3, Alexander Siemens theory and practice in electrical science (with experimental illustrations), Friday, February 10, Prof Charles Stewart, some associated organisms, Friday, February 17, Prof A H Church, F R S, turacin, a remarkable animal pigment containing copper, Friday, February 24, Edward Hopkinson, electrical railways, Friday, March 3, George Simonds, sculpture considered apart from archæology, Friday, March 10, Sir Herbert Maxwell, early myth and late romance, and Friday, March 17, William James Russell, F R S, ancient Egyptian pigments On Friday, March 24, a discourse will be delivered by Lord Rayleigh On March 31 and April 7 (the Fridays in Passion and Easter Weeks) there will be no evening meetings

THE following are the arrangements for lectures at the Royal Victoria Hall in January —January 3, Mr Charles E Reade on a trip through India, with anecdotes of the mutiny, January 10, Mr A. Hilliard Atteridge on some old Belgian towns, January 17, Prof Carlton Lambert on the romance of the stars, January 24, Dr Dallinger on spiders, their work and their wisdom

THE fermentative changes which the leaves of the tobacco plant are made to undergo before they are worked up and finally handed over to the public, are of the greatest importance in determining the quality of any particular tobacco It was formerly supposed that the alteration in its condition thus brought about was due to purely chemical changes induced by the process of "sweating" which the leaf undergoes, but some interesting experiments made recently go to show that these important results are effected by special micro-organisms. In a paper read before the German Botanical Society, Suchsland gives an account of some investigations which he has been conducting on the bacteria found in different kinds of tobacco He has examined fermented tobacco from all parts of the world, and found large numbers of micro-organisms, although but few varieties, mostly only two or three different species in any particular brand and but rarely micrococcus forms But what is of especial interest is the discovery that pure cultures of bacteria obtained from one kind of tobacco and inoculated on to another kind, generated in the latter a taste and aroma recalling the taste and aroma of the original tobacco from which the pure cultures had been in the first instance procured Thus it may be possible in the future to raise the quality of German tobacco, not, as heretofore, so much by careful culture and judicious selection of varieties, which has so far proved unsuccessful, but by inoculating pure cultures of bacteria found in some of the fine foreign tobaccos on to our own raw material, whereby similar fermentative changes may be induced and the quality correspondingly improved The further results promised by Suchsland will be looked for with much interest In connection with the above experiments on the "transplantation," so to speak, of micro organisms, it is interesting to note some results obtained lately by Nathan (*Die Bedeutung der Hefenreinzucht fur die Obstweinbereitung*) The amount of alcohol present in such wines as cider, currant wine, etc., is generally from 3 to 4 per cent This small proportion is possibly in part due to the necessarily large dilution of the fruit with water, which considerably reduces the nitrogenous constituents of the "must," and also to the fact that the yeast, according to Hansen mostly present on sweet fruits is the *Saccharomyces apiculatus*, which only possesses a feeble fermentative power Experiments were made to see whether, by increasing the nitrogenous constituents of the "must," and introducing a pure cultivation of a vigorous wine yeast, the yield of alcohol would be greater It was found that by adding a small amount of nitrogenous material, such as 0 15 gram ammonium chloride, and 5 cubic centimetres of wine yeast per litre to the "apple-must" (which was the fruit selected) 2 per cent more alcohol was obtained, and not only was this the case, but this cider possessed a finer and more vinous taste than that untreated, or which had only received an additional supply of ammonium chloride without the wine yeast Kosutany in a paper published in the *Landw Versuchsstationen*, 1892, has recorded the results of his investigations on the behaviour of certain species of wine yeast He states that not only is the percentage of alcohol yielded very different with particular yeasts, but that also the taste, smell, and bouquet of the wine inoculated with special cultures were distinctly different according to the variety of yeast employed It is hoped that, as in the case of tobacco so with wine, it may be possible to raise the quality by the judicious transplanting of bacteria obtained from finer brands

THE additions to the Zoological Society's Gardens during the past week include a —— Squirrel (*Sciurus* ——) from China, presented by Mr Julius Neumann, a Crowned Hawk Eagle (*Spizaetus coronatus*) from South Africa, presented by Mr T H Mills, a Macaque Monkey (*Macacus cynomolgus* ♀) from India, deposited, three Sulphury Tyrants (*Pitangus sulphuratus*) from South America, six common Widgeons (*Mareca penelope*, 3 ♂, 3 ♀), four common Pintails (*Dafila acuta*, 2 ♂, 2 ♀), two Pintailed Sand Grouse (*Pterocles alchata*, ♂ ♀) European, purchased.

OUR ASTRONOMICAL COLUMN

JUPITER'S FIFTH SATELLITE.—Mr A A Common, in a letter to the *Times* for December 28, writes with respect to the fifth satellite of Jupiter :—

"This extremely difficult telescopic object discovered by Prof Barnard last September at the Lick Observatory has been looked for with the 5ft reflector on several occasions On October 18 and on December 13 it was pretty certainly seen, by me on the first occasion, and by Mr Albert Taylor on the second. The last two evenings (Sunday and Monday) have been very fine, and on each, between five and six o'clock, the satellite has been seen with certainty by Mr Taylor and in glimpses by me.

"The brightness seems less than that assigned to it by Prof Barnard, but this may be due to the very much better sky they enjoy at Mount Hamilton, the glare from Jupiter would be with them very much less, so that they would have the planet on a much darker background, and it would appear brighter than it does here

"I have not heard of any other observations having been made out of America."

COMET BROOKS (NOVEMBER 20, 1892) —*Edinburgh Circular*, No 36, gives the ephemeris of this comet, from which the following extract is made This comet, according to Ber-

berich's computations, will soon commence to decrease in brightness

Berlin, Midnight.

THE MARKINGS ON MARS —In No 25 of the Publications of the Astronomical Society of the Pacific, Mr Schaeberle has a preliminary note on the question as to whether the darker and the brighter areas on Mars are water and land or *vice versâ* Having observed the planet from June 11 up to the present time he has been led to the conclusion opposite to that of Schiaparelli, Flammarion, and other observers, and considers that after all the dark portions should be considered as land and the bright as water. In raising such a question as this Mr Schaeberle has been very reserved, for should his opinion receive due attention, as of course it should do, and be corroborated, the planet's surface will be looked upon in quite a different light than formerly In this note he sets forth a few of his reasons for coming to such a conclusion, and it may interest many of our readers if we state some of them briefly If the dark markings be taken as land, would not the irregular gradations of shade be more naturally expected than if we consider them as fixed surface features? "Light reflected from a spherical surface of water in a slight state of agitation would vary uniformly in intensity At opposition, the centre of the planet would, for a water surface, appear brightest Observations show that within a certain distance from the edge of Mars there is a gradual increase in the steady lustre of the brighter areas towards the centre of the planet" Assuming these dark areas to be water, then they should thus be least dark near the centre, which is somewhat contrary to observation With reference to the "canals," he says that they on this hypothesis "correspond to the ridges of mountains which are almost wholly immersed in water," while with regard to their observed doubling he remarks that they can be explained as "representing parallel ridges of which our own earth furnishes examples" As a concluding argument he takes an observed terrestrial observation, the view of the lower end of San Francisco Bay from Mount Hamilton, San Francisco being fifty miles away At all hours of the day, he says, "the surface of San Francisco Bay (as seen from the top of Mount Hamilton) is much *brighter* than the neighbouring valley and mountains at the same distance" He further adds that the line of sight makes an angle of more than 87° with the normal to the surface of the bay, while the observer's position "varies all the way from being nearly in a direct line between the bay and the sun to the position in which the sun is nearly in the direction of the bay"

THE LICK OBSERVATORY —Miss Milicent W Shinn is the writer of a very interesting pamphlet on the history of the Lick Astronomical Department of the University of California In these few pages she brings together much with regard to the early events connected with the founding of the giant refractor that is not generally known. For instance, it is curious to read how Mr Lick wished to be immortalized by leaving bequests for costly statues of himself and his family, and when urging that such statues would be preserved for all time, was answered by Mr. Staples that "more likely we shall get into a war with Russia or somebody, and they will come round here with warships and smash the statues to pieces in bombarding the city" Mr Lick was so struck by this, that he asked, "What shall I do with the money, then?" How this question was answered is now well known, and astronomical science was presented with the finest object-glass that was ever made

Mr Lick's deed prescribed that the Observatory should be "made useful in promoting science," and up to the present these words have been carried out to the letter The big telescope has not been preserved for one side of astronomical science, but has dived into all branches, as every astronomer is aware Not only have minute double stars been observed and measured, but the spectroscope has been employed, from which excellent results have been published, while lunar photographs, equalling, if not excelling, those that had been previously obtained have brought to light much to set us thinking about Jupiter's fifth moon is perhaps the latest arrival of which we have heard, and this, following just 300 years after Galileo's discovery, would alone render the Observatory famous That the Lick Astronomical Department, during the few years of its existence, has done an immense amount of good work, especially when one takes into account the comparatively small staff on hand, cannot be denied, and we hope the day will come when the number of such telescopes will be increased, for the ever-opening fields of research point out how necessary they are

WASHINGTON MAGNETIC OBSERVATIONS —The United States Naval Observatory has quite recently published their magnetic observations that were made during the past year, prepared on the same plan as that for 1889–90 The observations for 1891, as Mr Hoogewerff (who was in charge for the greater part of the year) informs us, are better than those of former years, owing to the fact that the reductions took place at no very distant dates from the observations, the experience thus gained helping to correct and guard against conditions which might have tended to give rise to errors The introduction contains a description of the buildings, methods of observing, together with the personnel during the year, concluding with a description of the tabular results The tabular results, as usual, show the mean hourly readings for the elements for each month, Table I containing the mean values for the four years 1888–91

Simultaneous with this volume was also issued the meteorological observations and results for the year 1888

GEOGRAPHICAL NOTES.

A SPECIAL number of the *Mouvement Géographique* is devoted to a series of important despatches from M Alexandre Delcommune, chief of the Lomami expedition of the Katanga Company Entering the Lomami from the Congo, the party left the river on May 13, 1891, and explored the entirely untraversed territory between its upper valley river and that of the Sankuru as far as 8° S Thence they turned eastward and reached Lake Kassali on the Lualaba, and struck south through Garenganze's country to Bunkeia Making a circuit through Katanga and westward, they found the Lualaba near its source, and following it for 200 kilometres, discovered a grand gorge at Nzole, where the river flowed in a succession of wild cataracts between cliffs nearly a thousand feet high, and not more than forty yards apart From the rapids they returned to Bunkeia, travelled north eastward over the plateau, crossing the Luapula at its outflow from Lake Moero, and ultimately reached Lake Tanganyika The difficulties overcome were very great, and the sufferings of the caravan have rarely been surpassed even in the grimmest records of African travel

AMONGST the English travellers who have recently arrived in London are Mr. Selous, the famous South African hunter, and Mr Conway, who has probably climbed higher than any other European in the Karakoram range Both gentlemen will read papers to the Royal Geographical Society early next year

THE arrangements for the Royal Geographical Society's evening meetings after Christmas are unusually varied Mr Hose will describe his journey up the Burram river in Sarawak to Mount Dulit, at the first meeting in January The second meeting will be devoted to the Island of Yezo, when Prof Milne and Mr. Savage Landor will read papers Papers by Captain Bower and the American traveller Mr Rockhill, on Tibet, will be given later, and Lieutenant Peary will personally describe

his experiences in the north of Greenland In March Prof Bonny will lecture on the action of ice in producing geographical forms, and there will be other papers dealing with the scientific basis of geography

THE death of Cardinal Lavigerie on November 24 removed one of the most powerful personages who have recently influenced the geography of Africa. It is very largely on account of his labours that the French Roman Catholic missions have played so conspicuous a part in combating the slave trade, and to him also is due the formation of a much-needed Belgian Anti slavery Society

THE British Government having decided to relieve the East African Company from the responsibility of occupying Uganda, an Imperial commission, under the charge of Sir Gerald Portal, will set out from Mombasa as soon as it can be got ready to take over the administration of the country Another fact of some interest is the revival by Mr Cecil Rhodes of the idea of exploring Africa by telegraph He proposes to lay down a line from the Cape to Uganda, and ultimately to extend it to Egypt In a few months the South African Company's wires will have reached the mission station of Blantyre north of the Zambesi, and there are no serious physical difficulties in continuing the line to the head waters of the Nile The effect on the exploration of Africa will be enormous, not the least important result being the possibility of arriving at the true longitudes of places in the interior of the continent

DEW AND FROST

A PAMPHLET recording some interesting "Observations on Dew and Frost," by the Hon R Russell, has just been published by Mr Edward Stanford We reprint Mr Russell's "Summary of Results" —

The observations were begun with the object of verifying the commonly received theory of dew, and with a strong feeling that the results obtained by Col. Badgeley, described in the *Proceedings of the Royal Meteorological Society* for April, 1891, opposed as they were in some measure to the accepted teaching on the subject, would not be corroborated When, after exposing inverted glass tumblers and pans on grass and bare earth in the summer of 1891, dew was often found in surprising amount in the interior, I attributed the deposit to vaporous air which might have entered under the rim and parted with its moisture in the calm of the inclosed space But when it was found that a tumbler pressed down into dry earth, and other vessels admitting little air from outside, were considerably bedewed in the interior, and when, further, similar vessels inverted on earthenware or metal plates were found to be very slightly or not at all bedewed inside, it became more probable that the vapour condensed in the interior of vessels over grass and garden earth had proceeded from the earth beneath Next, it was found that china plates, admitting a flow of air between their lower surfaces and the ground, were more heavily bedewed on their lower than on their upper surfaces, and that a cylinder of glass was most bedewed on the lower outer and upper inner surfaces. These observations confirmed the suspicion that the dew on the inside of the hollow vessels was derived from the ground It was for a long time a matter of doubt and difficulty that vessels inverted over dry, dusty earth and dry turf were found copiously bedewed within on the morning following exposure On many mornings the amount of dew in the interior increased in some proportion to the precautions taken to exclude free air, and it seemed highly improbable that moist air penetrated, without depositing on its way much of its moisture, either through the dusty earth banked round the edges of the vessel, and exposed to the sky, or else through the dusty covering of earth below the vessel from lower layers

In December, 1891, during hard frost and very fine weather, with calm or very light airs, the ground being frozen hard, leaves of bushes, ferns, &c., were seen to be frosted both on their upper and lower sides, though much less on the lower sides facing the bare ground than on the upper sides facing the open sky Where thick fern grew between the observed leaves and the ground, there was no rime on the lower sides of the overhanging ferns or leaves This seemed to show that the rime on the lower sides of ferns was due to exhalation from the ground, for the interruption of radiant heat from the earth by dry litter would rather favour than reduce the frosting of the under sides. Live leaves on bushes, and dead leaves on the ground, were whitened with frost on their upper sides, and had a thin film or coat of transparent ice on their lower sides Leaves and sticks on the ground were less frosted on the sides facing the ground than on the top Thick planks between a few inches and one foot above the ground were about a third as much frosted on the lower as on the upper sides Considering that the upper side of a plank 1 inch thick would fall to a considerably lower temperature by radiation than the lower side, it may be supposed that the deposition would have been largest on the lower side if they had been at the same temperature That much frost came from the air independently of the ground, was shown by the white roofs 12 feet above the surface of the earth. On the other hand the grass was much more heavily frosted Moreover, tumblers inverted and pressed down on dry, hard, bare earth, on sand, and on hard turf, were moderately frosted inside, besides being thickly frosted outside The indications, on the whole, seemed to resemble those of the previous June, but the vapour condensation attributable to exhalation from the earth bore a much smaller proportion to the total deposit than in the case of dew on interior surfaces observed in summer

Boards, tiles, and stones (sandstone) in heaps were frosted on the top, and especially in cracks and indentations of the top surface, but not in the interstices between the separate pieces Stones on the ground were sometimes not frosted at all on the top, but much on the parts against the sandy earth, and where bedded in the ground

Further experiments in May and in the summer months of 1892 gave strong confirmation of the evidence that much dew and frost are caused by exhalation of vapour from the earth, even in dry weather

The facts that—

(1) A large quantity of dew was invariably found on clear nights in the interior of closed vessels over grass and sand

(2) Very little or no dew was found in the interior of vessels inverted over plates on the ground

(3) More dew was found on the lower side of a square, slightly raised, china plate over grass or sand than on the lower side of a similar plate placed upon the first

(4) The lower sides of stones, slates, and paper on grass or sand, were much more dewed than the upper sides The flat wooden back of the minimum thermometer on clear evenings when lying on earth, sand, or grass was almost invariably wet before the upper surface

(5) The lower side of plates of glass, 1 or 2 in above grass, were as much or more bedewed than the upper sides.

(6) Leaves of bushes, leaves lying on the ground, and blades of grass were about equally bedewed on both sides

(7) The interior of closed vessels inverted on the grass and covered with two other inverted vessels of badly-conducting substance was thickly bedewed, and the grass in the three circular inclosures also thickly bedewed

(8) The deposit of dew on the interior of closed vessels inverted over dry garden earth was much less than over sand or turf, although the powdery condition of the earth in the morning showed that no deposit from the air had taken place on its surface during the night

(9) Usually a greater amount of dew was deposited in the interior of vessels when the earth was moist at a little depth below the surface than when the earth was at its driest.

(10) The temperature of the space under a glass plate or other object suspended near the surface of the ground was higher than that of the upper surface of the object, and, nevertheless, a cloudy film was produced first on the lower surface,—amounted to a proof that a large part of the dew formed is derived from vapour from the earth

Moreover, the large difference often observed between the quantity of dew deposited in the interior of a vessel inclosing a plant, and the quantity of an empty vessel, proved that much dew may be derived from the earth through plants

Drinking glasses inverted over grassy turf, and over turf close by, from which the grass was removed, showed a similar excess of deposit on the glasses inclosing grass. More vapour was condensed on plates suspended over grass than over bare earth. In these cases the conditions are somewhat artificial, and the grass, which was covered by a suspended plate or inclosed by a glass, would be warmer than if the exposure to the sky were free, but the disturbance thus caused would tell as much against as in favour of deposition on the interior surface. It may be objected that the air in and above the grass would be colder, owing to the radiating grass, than over the bared spot, and that

therefore more dew would be deposited from the air, but this objection would scarcely be valid where a small plant was inclosed on bare earth and the deposition on the interior of the glass compared with that on a glass not inclosing a plant

Recent investigations have proved the evaporation from plants to be very large, and since evaporation proceeds by night as well as by day, there can be no reason why a moderate proportion of the dew deposited on the surface of blades of grass and on leaves of plants generally should not be derived from the vapour which they exhale The fact that an equal quantity of dew is deposited on glass, china, painted wood, &c., exposed to the sky to that deposited on grass, may seem to minimize the influence of plant exhalation, but we must remember that the whole of the stratum of air near the ground is rendered more vaporous by these exhalations, and that therefore the dew point is sooner reached on the surface of any body exposed to the sky in the midst of vegetation than on bare open ground Moreover, the thickness of the substance prevents earth heat from much affecting the upper surface The effect of grass in promoting dew formation is owing—(1) To its radiative power cooling its surface below the dew point (2) To the consequent cooling of the stratum of air in and over the grass to a point much below that of the air a few feet higher (3) To the obstruction offered by the grass to any light air or breeze on a nearly calm night, and the consequent settling down, without much disturbance, of a cold heavy stratum (4) To the prevention by the grassy covering of the drying up process by sun and wind which takes place on bare ground, and to the moist earth which therefore exists under grass near the surface even in dry weather (5) To the exhalation of vapour from the grass

The realization of these causes explained what was always, previous to these observations, a difficulty to me, the almost entire absence of dew on heather and dry fern in the summer Even after heavy dews, heather was invariably found perfectly dry In fine, calm winter weather, with white frost, heather may be a good deal whitened, and the frost is then derived largely from the open air Wood, being a good radiator and bad conductor, is heavily bedewed and frosted

Stones, whether of sandy composition and appearance, or of close grain like flint, pebbles, and slate, are not often visibly bedewed or frosted on the top on clear nights. On their surfaces, touching or very close to the ground, they are heavily bedewed and frosted A moderate radiative power, their usual situation removed from grass and vegetation, and in the case of the close grained stones, a conductive power greater than that of leaves, grass, and wood, though less than that of metals, prevent the deposition of much atmospheric moisture on their exposed sides But when air highly charged with vapour impinges on them in a confined space, as on their lower sides, condensation readily takes place, just as it will take place when any substance, even polished metal, is held above the spout of a kettle of boiling water It is apparent that since stones act as condensors to the vapour constantly arising from the earth, and since the heat of the sun and temperature of the air by day only slightly raise the temperature of the earth immediately beneath a large stone, while the radiation of heat from the stone and low air temperature of the night cause the lower side of the stone to be very cold at night, a rather large amount of moisture must be deposited on its lower surface in every twenty-four hours, and the ground on which it rests must in our climate remain always very moist The space between the stone and the ground consequently becomes the abode of many insects which live well in damp and darkness

Occasional observation of the distribution of dew, without careful comparison with the state of the weather, gives an impression of capriciousness which only continuous records comprising various conditions can remove.

Deposition is generally favoured by a humid air, and therefore in this country by southwesterly and westerly winds, which bring over the land the vapour derived from evaporation of the Atlantic Ocean. A smaller fall of temperature by radiation brings about condensation, and there is less tendency in any deposit to evaporate than in a drier air Radiation may produce a greater fall of temperature in dry air, but the distance from the dew-point is commonly too wide to compensate greater humidity with greater cooling

Calm is also very favourable to dew-formation. It allows parcels of vapour in the air to remain sufficiently long in contact with cold radiating substances to become greatly cooled, and so to become condensed upon them, and it prevents the dispersion of the stratum of air near the ground, which is continually cooling by contact and radiation Thus dew goes on forming while the air falls lower and lower beyond its original dew point, and while by a very gentle movement an interchange is kept up between the warmer air touching the ground beneath the grass, and the cold air on the surface of the grass, and between differently cooled layers and portions of air above it If the air is very humid, a very slight air or breeze is favourable to heavy deposition. On ordinary clear nights, calm and light airs allow the reduction of the lowest stratum of air to the dew point, and there is no liability to evaporation of the minute deposited particles by portions of air above the dew point being driven against them When the air is rather dry, as often happens at night in dry summer weather, and in winter frosts, calm is frequently a necessary condition for the deposit and appearance of dew and white frost The deposit may be observed to take place on the cessation of wind, and again, the change from calm to wind soon dries off the dew which has already formed On other occasions, when there is a gentle air or breeze, dew and frost are deposited only in sheltered places, as on the most sheltered slopes of fields, on banks sloping to leeward, on leaves on the lee side of bushes and trees, on the lee side of mole-hills, posts, railings, and other objects Hollows, depressions, and cracks, in paper, glass, stones, tiles, wood, and leaves, are more bedewed than flat surfaces from the same reason,—the reduction below the dew-point of air less diluted than that which is more free by currents of higher temperature and greater dryness With a fresh west wind in a clear night, the raised and ribbed parts of leaves, &c, may be thickly bedewed and frosted, but the hollows and folds scarcely if at all less, and the sides of buds, thorns, &c, are more frosted than the points The wind is, in fact, often sufficiently removed from the dew point to prevent deposition or continuance of moisture on all parts which are fully exposed to it Not even free radiation to a clear sky then avails to plant frost growths upon the object whose temperature is being perpetually supplied by the forcible impact of warmer air

Free radiation or exposed situation is, on the whole, perhaps the most effectual cause of dew on very many nights in the year In a level country those parts of a field which are least sheltered by trees and hedges gather most dew and frost on calm nights Similarly, those parts of any flat substance, such as a sheet of glass or paper, which have the most uninterrupted exposure to the sky are most bedewed The tops of bushes, posts, railings, inverted drinking glasses, pans, &c, are on calm nights, and sometimes breezy nights, more bedewed than the sides Greater cold by greater radiation in these cases produces greater deposition from the cooled air which comes in contact with the freely radiating surfaces It must be remarked, however, that radiation from fine points, such as the tips of sharp thorns, is often not sufficient to counteract in air which is not very humid the effect of the continual impact of air above the dew-point and higher in temperature Close to the ground the case is different, for there the temperature of the low stratum of air is lower, and usually about the dew-point, there is little movement, and vapour from the ground increases humidity, but even in this situation the points of grasses, &c., are often less bedewed than the sides.

That free radiation is by no means necessary for the formation of heavy dew on grass is proved by the experiments detailed above, made during the summer of 1892 The grass was found heavily bedewed in dry weather within three enclosures of earthenware by which radiation was arrested

Since grass covered by hollow vessels, and the interior of hollow vessels themselves, are thickly covered with dew, it would seem likely that the grass under overhanging trees would be as thickly bedewed as the exposed grass in a field, and that the under sides of the overhanging leaves would also be wetted This is not the case. And there are differences in the two situations sufficient to account for the absence of dew under leafy trees In the first place, on a calm night, the air under a tree is warmer than in the open owing to radiation from the ground being arrested Secondly, whatever vapour escapes from the earth is unable to condense on the grass which covers it, the grass being but little colder than the air and vapour Thirdly, and herein lies the chief difference, the air under the tree moves freely and is above the dew-point, since the earth and other objects which it touches are warmer than the grass and air outside. If the air were confined in a small space, the increments of vapour issuing from the earth, and the gradual cooling of the grass under the tree and of the tree itself, might cause deposition, but air which has parted with much of its moisture outside is

constantly mixing with a considerable body of air already warmed under the sheltering canopy. Thus all objects under the tree remain above or not much below the dew point of the air which touches them. Yet, on a calm night, long grass and other substances a little raised above the ground are sometimes heavily bedewed, though largely hindered by overhanging branches from losing their heat by radiation. They often remain nearly dry till the morning hours, and then reach a temperature below the dew-point. The absence of dew under trees and bushes is, within limits, roughly proportional to the area of ground covered. A large surface of dry ground slowly parting with its heat during the night has a powerful effect in preventing condensation. Small bushes on a humid clear night are often much bedewed even on their lower leaves. On the night of October 5, 1892, both sides of the leaves of bushes in all sheltered situations were found thickly bedewed, but where leaves were either exposed to the slight breeze which was blowing, or near the wall of the house on which the sun had shone, they were dry. The warm, dry wall of a house acts a part similar to that of the earth under a tree in radiating warmth to neighbouring objects, and in warming the air by contact. The vapour emerging from earth sheltered by foliage several feet above it has time to mix well with air before coming in contact with solid objects. In the hollow vessels, and even in the space between a raised plate of glass and the earth, the vapour which rises from the earth has no time to become equally distributed in the air before meeting with substances colder than itself; in the closed vessels the initial amount of vapour is augmented so as to produce constant saturation. Objects, such as drinking glasses, raised several feet above the grass, were seldom much bedewed, and often quite dry.

The increase of pasture-land in England must have a considerable effect in increasing cold by radiation, and in diminishing the amount of vapour in the air at night by deposition on grass. The sensible moisture at night must be increased near the ground, the dew point being quickly reached on a clear night over grass.

The large quantity of dew found on plates and other objects over sandy ground, dry to a depth of several inches, proves the possibility of a large emanation of noxious vapours from soil containing decaying organic matter below a covering of sand. The ague of parts of East Anglia and of sandy malarious districts may be thus accounted for.

Houses built on sandy ground over a damp subsoil may be considered as scarcely more wholesome than if built on the damp soil itself.

In late summer and early autumn the high temperature of the soil in comparison with the temperature of the surface and of the air near the ground at night, must have a powerful effect in the production of vaporous exhalations. The heavy rains which so often occur in October, the wettest month of the year, must co-operate with a falling air temperature in driving out air from the pores of the earth.

In nearly all the conclusions of Wells, as stated in his admirable "Essay on Dew," my observations lead me to concur. He found that calm is favourable to the precipitation of dew; that if, in the course of the night, the weather, from being calm and serene, became windy and cloudy, not only did dew cease to form, but that which had formed either disappeared or diminished considerably; that if the clouds were high and the weather calm, dew sometimes formed to no very inconsiderable extent; that dew often forms on shaded grass even several hours before sunset, and continues to form after sunrise; that, if the weather be favourable, more dew forms a little before, and, in shaded places, a little after sunrise, than at any other time; that on substances elevated a few feet above the ground it forms much later in the evening, but continues to form as long after the rising of the sun as upon the ground; that dew is more abundant shortly after rain than during a long tract of dry weather; that dew is always very copious on those clear and calm nights which are followed by misty or foggy mornings, and also on clear mornings after cloudy nights, and generally after hot days; that more dew was formed between midnight and sunrise than between sunset and midnight, owing doubtless "to the cold of the atmosphere being greater in the latter than in the prior part of the night;" that whatever diminishes the view of the sky diminishes the quantity of dew; that a substance placed on a raised board of some extent acquired more dew on a very still night than a similar substance lying on grass; that bright metals attract dew much less powerfully than other bodies, that a metal which has been purposely moistened will often become dry though similarly exposed with bodies which are attracting dew, and that wool laid upon a metal acquires much less dew than an equal quantity laid upon grass in the immediate vicinity; that a metal plate on grass always became moist on the lower side during the night, though the upper side was often very dry, but that if the plate was elevated several feet in the air, the condition of both sides was always the same, whether dry or moist; that wool on a raised board was commonly colder than on the grass on very still nights, and that the leeward side of the board was colder than the windward; that bare gravel and garden mould were very much warmer after sunset than neighbouring grass; that on dewy nights the temperature of the earth half an inch or an inch beneath its surface was much warmer than the grass upon it, and than the air; that metal covering grass was only slightly colder than the grass covered, and this again colder than the earth; that metal thus exposed was warmer than air 4 feet above it, and much warmer than neighbouring grass; that the variety in the quantities of dew, formed upon bodies of the same kind in different situations, was occasioned by the diversity of temperature existing among them; and that on nights favourable to the production of dew, only a very small part of what occurs is owing to vapour rising from the earth.

The last of these conclusions Wells supported by the observation that the dew on the grass increased considerably about sunset, the same time at which dew began to show itself on the raised board, and by the reflection that, "though bodies situated on the ground after they have been made sufficiently cold by radiation to condense the vapour of the atmosphere will be able to retain the moisture which they acquire by condensing the vapour of the earth; yet, before this happens, the rising vapour must have been greatly diminished by the surface of the ground having become much colder." He adduced the fact that substances on the raised board attracted rather more dew throughout the night than substances lying on the grass. He admitted that all the dew on calm, cloudy nights might be attributed to condensation of the earth's vapour, since on such nights the raised board was dry.

But if the grass was moist on these calm, cloudy nights, and the moisture were owing to earth-vapour, it is only reasonable to infer that a very much larger quantity was owing to earth vapour on clear nights when radiation was comparatively free. Moreover, the fact that substances on the raised board became wetter than substances on the grass may be attributed to the non conducting wood intercepting the warmth radiated from the ground, and thus allowing a substance on the upper surface of the board to become colder than a substance on the grass. And with regard to the "rising vapour" being greatly diminished by the surface of the ground having become colder, it does not appear that such diminution actually occurs, owing possibly to the influence of the high temperature of the preceding day reaching the moist earth at a little depth below the surface about the same time. I have found the deposition of earth vapour to proceed at a rapid rate after sunrise over grass.

Wells explains with much ingenuity the reason why leaves of trees often remain dry throughout the night, while those of grass are covered with dew. But he does not, I think, attach sufficient weight to the fact which he mentions among others, that the air near the ground is near one of its sources of moisture, while the tops of trees are removed from that source. The air is both damper and colder near the ground; a stratum of cooled air rests upon warm earth emitting vapour. The tops of trees are pervaded by air which is drier and warmer, and the leaves do not allow air to rest long enough on their cooled surfaces to part with sufficient heat in order that condensation may ensue.

I have found that when the air is clear and not humid, radiation into space is often not sufficient to cause visible dew or frost except in sheltered calm places, and in the same condition of air deposition takes place more on broad surfaces than on thin shoots, threads, and points, and more on the faces than on the edges of leaves. It appears necessary that a certain stability of temperature below that of the air, and a certain protection from re-absorption by the drier portions of air which pass over, should be attained in order that dew and frost may accumulate. When, on the other hand, the air is very moist, with a tendency to mist or fog, a very large condensation takes place on exposed objects, and especially on those which are at some height above the ground, such as the branches and twigs of trees. Points, thorns, spiders' webs, and other thin filaments are then heavily bedewed. Mist or fog often follows.

When some mist has formed on such a night, there is a heavy

precipitation on trees, &c., which is increased by wind, and large drops of rain on to the ground beneath them. This condition seems best explained by Aitken's discoveries showing the possibility of a super-saturation of air when the number of dust-particles is unusually small in a mass of air which is humid and cooled to saturation. The dust particles from their minuteness, and from their inability to fall below the temperature of the air owing to the cloud canopy above, do not condense much of the vapour, and consequently any solid object of the same or slightly lower temperature brings about precipitation from the passing air, which may possibly be super-saturated. A slight fall of temperature in the air, or sometimes an increase of dust particles, then produces fog. A dry fog may thus result from cold causing condensation on a very large number of dust-particles which are radiating heat rather freely, and a damp mist from partial condensation from super-saturated air on a comparatively small number of dust particles not radiating freely owing to a clouded sky.

These considerations explain why a dry fog is densest in London and a wet mist densest in the country. A dry fog is the work of cold radiating particles, a wet mist is the work of cold air mixing with warm. "In a fog," says Angus Rankin,[1] "the watery vapour in condensing has more particles to condense on, and consequently the particles of fog are smaller, and on meeting with an object with a higher temperature, instead of wetting it the object dries them up by parting with some of its heat. On the other hand, in a mist, the particles of dust, being few, have more water condensed on each, and so are larger and do not readily evaporate with small increments of heat." Yet in a damp mist the addition of a large number of dust particles, as in a town by day, scarcely increases the density of the mist. In fact, the wet mist is less dense in London than in the country, owing to the higher temperature and lower humidity of the air. Dry or radiation fogs, which cling to the ground, are the most dense in smoky places.

In fogs with frost in winter, such as have occurred several times in the last few years, I have always found the windward side of objects to be much more heavily frosted than the leeward, and the rime to attach itself most to points and edges. Trees have thus become laden with rime, even so as to break down branches; iron points of railings, splinters of wood, wires, and blades of grass have borne spikes and fern-like growths an inch or more long, and heather and fern in hollows have been whitened as if with a fall of snow. In weather of this kind it is difficult to say what is dew or frost proper, and what is deposited moisture from super-saturated air and from fog. On the same night a white frost may present the characteristics of fog-deposition in a valley and of clear condensation on a neighbouring hill.

Dew and frost are in fine the result of many causes which inter-operate in a complex manner. The importance of the laws of gases of the multitude of fine adaptations in the relations of vapour, air, water, earth, and plants; the importance, too, of the thermal receptivity of boundless space, gives an interest to this branch of meteorology which is second only to its beauty.

ARBORESCENT FROST PATTERNS

PROF. MELDOLA'S account of Arborescent Frost Patterns has excited a good deal of interest, and we have received many letters on the subject, some of which we have already published. To-day we give reproductions of photographs we have received from Mr. J. Maclear, Cranleigh. Fig. 1 represents a photograph of a facsimile tracing of a "Nature print" of an ice crystallite taken by Mr. A. Anderson on a still and sunny early morning in January 1887, after a not very severe frost. The sunshine had just dried the rest of the frost off the flagstone, and left this mud and ice-crystallization, which he promptly secured on soft paper by means of a soft pad-pressure, and thus got a perfect Nature printed impression. The original (now unfortunately lost) showed an appearance of vegetable (moss) growth, even more strikingly than in this tracing from it.

With regard to Fig. 2 Mr. Maclear writes:—"The melting ice under the dabbing pad formed a natural pigment with the mud on the flagstone, the rest of the flagstones being perfectly dry already by the early morning sunshine."

Prof. Meldola sends us the following interesting letter which he has received from Corbridge on Tyne:—

"I was much interested by your note in NATURE the other day, anent the frost markings of a vegetable pattern. I have seen just the same forms several times in the north, but it is I think the least common of the patterns usually met with. I write, however, to call your attention to Figs. 1 and 7 of Plate

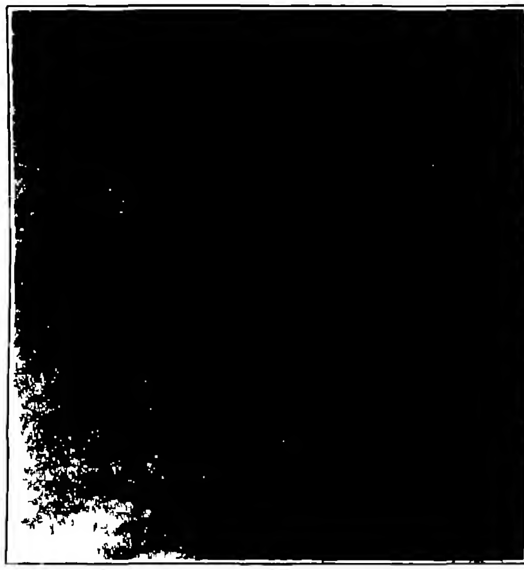

FIG. 1.—Ice crystallite, "Nature printed" by A. Anderson, January 1887. Facsimile tracing by J. Maclear, January 1887. Size of crystal 14¼ inches × 13¾ inches.

vii, illustrating the article on Meteorology in the "Encyclopædia Metropolitana" (1845, vol. i. of plates, vol. v. of text). These figures are very like yours and some of the others given with them are also very interesting. I have often shown my students when out in the fields in cold weather how exactly the mud

FIG. 2.—Photograph from the original "Nature print," made by Mr. A. Anderson, of an ice crystallite, January 1887. Size of crystal, 10½ inches × 7 inches.

cum frost markings of the common feathery volute type imitate the so called *Cauda galli* fossil fucoid (?) which is one of the most abundant objects on the surface of the carboniferous limestone courses about here. As far as form goes they are identical, and there is no structure to be discovered in the fossil markings.

"Corbridge-on-Tyne, December 16. G. A. LEBOUR."

PROF. SOLLAS writes to us:—The correspondence on this subject that has lately appeared in your columns (particularly Prof. Bonney's reference), leads me to anticipate a communication I hope shortly to present to the Royal Dublin Society on the growth of crystals. The arborescent forms assumed by ice are merely a special case of a very general problem—that of the

[1] *Journal of the Scottish Meteorological Society.* Third Series. No. viii.

forms assumed by crystals under different conditions Petrologists have long been familiar with the tendency of crystals developing in a viscid medium to excessive growth in one or more directions Felspar is a familiar instance, the lath-like forms which it frequently assumes being due to elongation along one axis (x), the length of prisms measured along this axis often exceeding by ten times that along the axis y or z The cause of this need not now be discussed, it will be sufficient to add that the phenomenon is not special to felspar, but is of quite general occurrence With this tendency is connected the origin of curvilinear forms We may consider the molecules forming the growing face of a long prism, the spheres of influence of these lie half within and half without the substance of the crystal. Considering this influence as attractive (directly or indirectly), we may say that the attraction of the molecules leading to further deposition is one half their total attraction If now from the face we pass to the edge between two faces at right angles, only one-quarter of the sphere will be immersed, and the attraction may be spoken of as three quarters of the whole, while if from the edge we pass to a corner, only one-eighth is immersed, and the attraction becomes seven eighths From this it follows that growth should be more rapid at the edges than over the surface of the face, and still more rapid at the corners In accordance with this we find young growing prisms in a viscid medium increasing so rapidly at the edges as to leave a space in and about the axis filled with the medium in a non-crystalline state Indeed, a viscid medium is not necessary, hollow prisms are of common occurrence whenever crystallization takes place with rapidity Further, in quite embryonic crystallites, Vogelsang figures elongated prism like forms, in which the four corners are produced parallel to the long axis into processes resembling spines There is an additional reason pointed out to me by Prof Fitzgerald why growth should be more rapid at the edges and corners than over the general surface, and that is that these parts are more exposed to molecular bombardment

If crystals are more readily built up along edges and corners, we should expect them to be more readily unbuilt in these regions, and this is in accordance with observation, the zonal felspars of igneous rocks, in the formation of which intervals of solution have alternated with periods of growth, usually present, in the outlines of each resulting envelope, rounded corners

The influence of corners is well seen in some glassy rocks where small prisms of felspar (andesite) may be observed, with five or six slenderer but longer prisms springing from a corner in radiate divergence

From this it is but a step to curvilinear growth Let a prism tend to rapid rectilinear growth, and any check immediately in front will lead to a forward growth from a corner in a slightly different direction, even the competition of molecules for this centre of attraction may by overcrowding bring about this result, and thus both branching and curvilinear forms may arise This is beautifully exemplified in the spherulites of many igneous rocks, where we find in the centre of a radiately crystallized sphere a long prism of felspar serving as a nucleus, and from the *ends* of this slender, almost linear, prisms diverge towards a spherical surface which by repeated branching and associated curving they everywhere reach, leaving about the sides of the nucleus a spherical space almost devoid of crystal structure The whole arrangement in median longitudinal section presents a remarkable resemblance to the lines of force as shown by iron-filings about a bar magnet

Evidently in rapid crystallization with a tendency to linear growth, divergence may be repeated at such frequent intervals as to produce forms which to the unaided eye appear to be continuous curves.

SOCIETIES AND ACADEMIES.

LONDON

Mathematical Society, December 8.—Mr A B Kempe, F R S, President, in the chair —The following communications were made —On a theorem in differentiation, and its application to spherical harmonics, by Dr Hobson.—On Cauchy's condensation test for the convergency of series, by Prof M J M Hill Cauchy's condensation test for the convergency of series is as follows —If $f(n)$ be positive for all values of n, and constantly decrease as n increases, then the series $\Sigma f(n)$ and $\Sigma a^n f(a^n)$ are both convergent or both divergent, where a is any positive integer not less than 2 There is a clear reason why a cannot be unity, for then $\Sigma a^n f(a^n) = \Sigma f(1)$, which is always infinite It is proved in Chrystal's "Algebra" that the theorem is also true if a have any positive fractional value not less than 2, see part 2, chapter xxvi, § 6, cor 1 The proof there given when a lies between the consecutive positive integers p and $p+1$ is based on Cauchy's proof for the two cases $a = p$ and $a = p + 1$ But this proof will not apply when $1 < a < 2$, because Cauchy's proof will not apply when $a = 1$ Yet it does not seem possible to assign a reason for excluding values of a between 1 and 2, for Cauchy's method appears to depend on this—viz that for increasing values of n the expression $f(a^n)$ occupies more and more advanced positions amongst the terms of the series $\Sigma f(n)$, but this is possible if $1 < a < 2$, as well as when $a > 2$ If $a \overline{\overline{<}} 1$, then this is no longer true The problem then considered in this paper is so to recast the proof for fractional values of a as not to exclude the case $1 < a < 2$ The complete theorem will then stand thus —If $f(n)$ be positive for all values of n, and constantly decrease as n increases, then the series $\Sigma f(n)$ and $\Sigma a^n f(a^n)$ are both convergent or both divergent if $a > 1$ The demonstration depends on the following theorems

I If $\Sigma a^n f(a^n)$ be convergent, then—

$$\sum_{n=1}^{n=\infty} f(n) < f(1) + \quad + f(t_s)$$
$$+ (a - 1 + a^{-s}) \left[\sum_{n=1}^{n=\infty} a^n f(a^n) - \sum_{n=1}^{n=s-1} a^n f(a^n) \right]$$

where s is any integer so large that

$$a^{s+1} - a^s > 1,$$

and t_s is the greatest integer in a^s, a being greater than 1

II (A) If $\Sigma a^n f(a^n)$ be divergent, and if $a^n f(a^n)$ diminish as n increases beyond a certain value, then

$$\sum_{n=1}^{n=\infty} f(n) > f(1) + \quad + f(t_s)$$
$$+ (1 - a^{-1} - a^{-s-1}) \left(\sum_{n=1}^{n=\infty} a^n f(a^n) - \sum_{n=1}^{n=s} a^n f(a^n) \right]$$

II (B) If $\Sigma a^n f(a^n)$ be divergent, and if $a^n f(a^n)$ do not diminish as n increases beyond a certain value, then—

$$\sum_{n=1}^{n=\infty} f(n) > \sum_{n=1}^{n=s} f(n) + \sum_{n=s+1}^{n=\infty} An^{-1},$$

where s is an integer taken large enough, and A is some finite quantity —Additional note on secondary Tucker circles, by Mr J Griffiths —Notes on determinants, by Mr J E Campbell In accordance with the late Prof Smith's notation, a determinant of the p^{th} class may be written

$$| a_{ijk} \quad |$$

The fact that a determinant of the second class (an ordinary determinant) is not altered if the vertical columns be written horizontally is expressed by the identity

$$| a_{ij} | = | a_{ji} |$$

For determinants of higher class it is known that any of the suffixes can be interchanged, except the first, and if the class be even, the first suffix can also be interchanged with any other, but for determinants of odd class this is not true By considering a cubic determinant as an ordinary determinant in alternate numbers, the author tries to explain this essential distinction between determinants of odd and even classes If the element $a_{pqr} = - a_{qpr}$, and $a_{ppr} = 0$, the determinant is called skew symmetrical It is easily seen that skew symmetrical determinants of even class and odd degree vanish identically This is analogous to the well known theorem in ordinary determinants, but there is no corresponding analogue to the theorem that skew symmetrical determinants of the second class and even

degree are perfect squares The reasoning which establishes these propositions does not apply to skew symmetrical determinants of odd class. By a different method it is shown that they vanish identically whether the class be even or odd It is next shown that if we form any determinant of even class $2p$ from $2p$ ordinary determinants, in a manner analogous to that in the rule for the multiplication of two ordinary determinants, the determinant so formed is the product of the $2p$ determinants, and if any determinant of odd class $2p + 1$ is formed from $2p + 1$ ordinary determinants, the determinant so formed is the product of the last $2p$ of these ordinary determinants into the first taken, with all its signs positive A somewhat similar result is shown to hold for determinants of alternate numbers As an application, let

$$z = \frac{a_1}{(x - \alpha_1)(y - \beta_1)} + \cdots + \frac{a_n}{(x - \alpha_n)(y - \beta_n)},$$

and let (p, q) denote

$$\frac{d^{p+q}z}{|\underline{p}\,|\underline{q}\,dx^p\,dy^q}$$

By multiplying the arrays

$$\left\|\begin{matrix} \dfrac{a_1}{x - \alpha_1} \\ \dfrac{a_1}{(x - \alpha_1)^2} \end{matrix}\right\| \qquad \left\|\begin{matrix} \dfrac{1}{y - \beta_1} \\ \dfrac{1}{(y - \beta_1)^2} \end{matrix}\right\|$$

we get

$$\begin{vmatrix} (0, 0), & (0, 1), \\ (1, 0), & (1, 1) \end{vmatrix} = \Sigma \frac{a_p a_q (\alpha_p - \alpha_q)(\beta_p - \beta_q)}{(x - \alpha_p)^2 (x - \beta_p)^2 (x - \alpha_q)^2 (y - \beta_q)^2}$$

Suppose, now, $n = 1$, we get that the primitive of

$$\begin{vmatrix} (00) & (01) \\ (10), & (11) \end{vmatrix} \text{ is } z = \frac{a_1}{(x - \alpha_1)(y - \beta_1)}$$

Similarly, by multiplying,

$$\left\|\begin{matrix} \dfrac{a_1}{(x - \alpha_1)} \\ \dfrac{a_1}{(x - \alpha_1)^2} \\ \dfrac{a_1}{(x - \alpha_1)^3} \end{matrix} \quad \cdot \quad \cdot \right\| \qquad \left\|\begin{matrix} \dfrac{1}{y - \beta_1} \\ \dfrac{1}{(y - \beta_1)^2} \\ \dfrac{1}{(y - \beta_1)^3} \end{matrix} \quad \cdot \right\|$$

we get that the primitive of

$$\begin{vmatrix} (00), & (01), & (02) \\ (10), & (11), & (12) \\ (20), & (21), & (22) \end{vmatrix} = 0,$$

is

$$z = \frac{a_1}{(x - \alpha_1)(y - \beta_1)} + \frac{a_2}{(x - \alpha_2)(y - \beta_2)}.$$

Similar primitives are obtained for differential equations, which are in the form of determinants of higher class A further application is obtained by taking powers of different invariantive symbols, of which (123) is the simplest for the ternary quantic The resulting invariants are seen to be determinants of some even class —A geometrical note, by Mr R Tucker —The President (Major MacMahon, F R S, in the chair) made an impromptu communication of a problem, the solution of which he thought would be subsidiary to the sought-for solution of the "stamp folding" problem

Linnean Society, December 15 —Prof Stewart, President, in the chair —The President announced the recent death of Mr H T Stainton, a Fellow and former Vice President of the Society, and of European reputation amongst entomologists, by whom his loss would be widely felt —Mr. D Morris exhibited a series of botanical photographs from the west coast of Africa, and gave some interesting details about the appearance and mode of growth of some of the more remarkable forest trees and plants of that region —The Secretary exhibited a large collection of photographs of Lichens, very neatly mounted and labelled, which had been recently presented to the Society by Prof Arnold, of Munich —On behalf of Mr George Swainson, of St Annes-on-Sea, Lancashire, Mr A R. Hammond exhibited an aquatic dipterous larva, belonging probably to the genus *Dixa*, of which by means of the oxyhydrogen lantern, with microscopic attachment, a good figure was projected on the screen. He referred to the different views which prevailed concerning the dorsal and ventral aspects of this larva, and pointed out that the tail plates possessed features which in allied forms were characteristic not so much of the larval as of the pupal stage —A paper was then read by Dr Maxwell T Masters, F R S, on the classification and geographical distribution of the *Taxaceæ* and *Coniferæ*, his remarks being illustrated by a specially prepared map, lent by Mr C B Clarke, and by specimens of the fruit and leaves of some of the more notable forms —Mr George Brook followed with a paper on the affinities of *Madrepora*, and here again, by means of the oxyhydrogen lantern, an excellent series of coral sections was projected, which illustrated very clearly the author's remarks on comparative structure —A short note on the abnormal form of the lens in the eyes of an albino rat, by Prof R J Anderson, was read on his behalf by the Secretary The meeting then adjourned to January 19, 1893

Zoological Society, December 6 —Dr St George Mivart, F R S, Vice-president, in the chair —The Secretary read a report on the additions that had been made to the Society's menagerie during the month of November 1892 —Dr Hickson read a paper entitled "A Revision of the Genera of the *Alcyonaria Stolonifera*, with a description of one new genus and several new species" The author commenced by stating the grounds upon which it might be considered desirable to retain the suborder Stolonifera, and criticized the views of those who place these Alcyonarians in the suborder Alcyonida Of the genera that had already been proposed only four could now be retained, namely, *Tubipora*, *Clavularia*, *Cornularia*, and *Sympodium*, and the author proposed to add one more, namely, *Stereosoma* The genera *Sarcodictyon*, *Rhizoxenia*, *Cornulariella*, *Anthelia*, and *Gymnosarca* must be abandoned, and the species incorporated in the other genera. A description was then given of the new genus *Stereosoma*, a form found on the coast of North Celebes, distinguished from all other Stolonifera by certain characters of its tentacles and by the absolute non retractability of its polypes Several new species of *Clavularia* were then described from North Celebes, Diego Garcia, and Australia This was followed by a summary of all the species of the genus known to science —Mr F E Beddard, F R S, read a description of the convolutions of the cerebral hemispheres in certain rodents. The paper referred chiefly to *Dasyprocta Cœlogenys*, *Lagostomus*, *Hydrochœrus*, and *Dolichotis*, being the genera of rodents in which the brains show the greatest development of convolutions —A communication was read from Prof Collett, containing a description of a new monkey from S E Sumatra, for which he proposed the name *Semnopithecus thomasi* —Mr H J Elwes read the second portion of an account of the butterflies collected by Mr W Doherty in the Naga and Karen Hills and in Perak

PARIS

Academy of Sciences, December 19.—Annual Public Meeting —The President, M d'Abbadie, gave a brief survey of the life and work of those lost to the Academy by death during the year Among these were the following members M D D A Richet, distinguished for his medical discoveries, M de Quatrefages de Bréau, the naturalist; M Jurien de la Graviere, Vice Admiral under the Empire, M Pierre Ossian Bonnet, geometrician; Admiral Mouchez, late Director of the Paris Observatory Foreign Associate Sir G B Airy *Académicien libre* M Lalanne Correspondents MM Gilbert, Abria and Adams The prizes were awarded as follows: The Grand Prize of the mathematical sciences to M Hadamard for his solution of the problem of determining the number of primary numbers inferior to a given quantity One Prix Bordin to M Gabriel Koenigs for his solution of a problem concerning geodesic lines, another to M Humbert for his work on hyper-elliptic surfaces The Prix Poncelet to the builders of the Forth Bridge, Sir John Fowler, and Sir Benjamin Baker, the Extra Prize of 6000 francs to M Hédouin for his work on the Channel currents; the Prix Montyon to M N J Raffard, civil engineer, the Prix Plumez to M Augustin Normand, for his geometry of ships In Astronomy, the Prix Lalande was doubled, and awarded to Mr Barnard and Mr Max Wolf; the Prix Damoiseau to M Radau for his work on lunar inequalities of long period caused by planets, the Prix Valz to M. Puiseux for his researches on the *equatorial coudé* and other instruments; the Prix Janssen to M. Tacchini for his solar work Statistics: The Prix Montyon to MM M

Bastié and J Dardignac for works on the population of France and hygienic statistics respectively. Chemistry The Prix Jecker to M Bouchardat for his researches on the terebene carbon compounds Mineralogy The Prix Vaillant to M Lacroix for his work on the application of optical characters to the determination of rocks and mineral species Botany - The Prix Desmazières to M Pierre Viala for his "Maladies de la Vigne", the Prix Montagne—1000 francs to M l'Abbé Hue, and 500 francs to Dr F Xavier Gillot for their mycological researches, the Prix de la Fons Mélicocq to M Masclef for his "Botanic Geography of Northern France" Medicine and Surgery Prix Montyon—one to MM Farabœuf and Varnier for work on obstetric medicine, another to M Javal for ophthalmometry, a third to M Lucas Championnière for his work on hernia, the Prix Barbier was shared between M Laborde ("Death by Chloroform") and MM Cadéac and Albin Meunier ("Alcoholism," &c), the Prix Bellion to Dr Theodore Cotel for his work on "The Education of the Senses", the Prix Lallemand was shared between M Binet ("Les Altérations de la Personnalité") and M Durand ("Les Origines Animales de l'Homme") Physiology the Prix Montyon to M Hedon (diabetes) and M Cornevin (breeding of domestic animals), the Prix Pourat to M H Roger for his researches on the inhibitory power of the nervous shock Physical Geography the Prix Gay to M. Moureaux (distribution of magnetic elements in France) General Prizes Prix Montyon, for improvements in unhealthy industries, to M L Guéroult (crystal cutting), the Prix Delalande Guérineau, to M Georges Rolland for his work on the Algerian Sahara, the Prix Jérôme Ponti, to M Le Chatelier for his researches on dissociation and chemical equilibrium, the Prix Leconte (50,000 frcs) to M Villemin for his demonstration of the specific nature and the transmissibility of tuberculosis The *Comptes rendus* contains a complete list of the prizes to be awarded in the next few years

BERLIN

Physical Society November 18 —Prof Du Bois Reymond, President, in the chair —Prof Neesen gave an account of experiments made with a view to the photographic recording of the oscillation of projectiles He employed hollow projectiles in whose interior was placed a sensitive plate, illuminated by sunlight through a small opening During its rotatory flight the ray of light described curves on the plate from whose position, taken in conjunction with that of the sun, the oscillation of the axis and point of the projectile would be calculated The results obtained showed that both the axis and point perform oscillatory movements during the flight which are very different from those usually believed to take place In order to study these more accurately, Prof Neesen is busy with the construction of some arrangement which may admit of the introduction into the projectiles of sensitive plates which shall not participate in the rotatory motion

December 2 —Prof Du Bois Reymond, President, in the chair —Dr Du Bois gave an account of experiments made by Mr Shea in Berlin on the refraction of light in metals, and in connection with this referred to a theoretical treatise which he had recently published on the same subject in conjunction with Dr Rubens

Physiological Society, November 25 —Prof Du Bois Reymond, President, in the chair —Dr Treitel gave an account of observations he had made on two snails enclosed in air-tight glass vessels. Dr Ad Baginski gave an account of a very fatal epidemic among rabbits in the same hutch, in which a post-mortem examination of the dead and also showed a serious affection of the liver and intestinal mucous membrane. The liver was filled with cysts of various sizes, in which, together with coccidia, some very remarkable growths were found, which led to very marked changes of the epithelial cells —Dr Rawitz made a short preliminary statement of observations on Annulata made during his stay at the biological station of Rovigno, on the coast of the Adriatic. While one species was found to be extremely sensitive to light, and to draw in its tentacles at once when shaded, another closely related species was quite unresponsive, while, on the other hand, it reacted immediately to the slightest touch The first species was much less sensitive to touch.

AMSTERDAM

Royal Academy of Sciences, October 29.—Prof. van de Sande Bakhuyzen in the chair. —Prof Engelmann spoke (1) on the influence of central and reflected irritation of the nervus opticus on the movement of the cones of the retina, and (2) on the theory of the contraction of muscles —Prof. Schoute proved the following theorem —If $\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$ is the equation of a given ellipse, E, and $f_n(x,y)$ contains the terms of the nth order of the equation of a curve C^n with reference to the same axes The sum A of the eccentric anomalies a_k of the $2n$ points S_k common to E and C^n is determined by the relation

$$e^{iA} = \frac{f(a, ib)}{f(a, -ib)}.$$

He indicated several peculiar cases of this general theorem —Prof Kamerlingh Onnes communicated some measurements, by Mr Leeman, relating to Kerr's phenomenon when reflection takes place at the pole of a cobalt magnet The constancy of the difference of phase S, discovered by Dr Sissingh was confirmed The measurements agree with the theory of Goldhammer, contrary to that of Drude Mr Leeman finds a magneto optic dispersion in S

November 26 —Prof van de Sande Bakhuyzen in the chair —Prof Schoute continued his communication of October 29, on a general theorem in the theory of plane curves, and corrects a theorem of Laguerre —Prof Lorentz dealt with the relative motion of the earth and the luminiferous aether —Prof Kamerlingh Onnes spoke of measures on the relation of spark length and difference of potential made by Dr Borgesius at Groningen with a double bifilar electrometer of his own construction The differences hitherto found are explained by a correction for pressure and temperature having been omitted Discharge between two concentric cylinders depends, as Gaugain stated, on the density of the inner one only Provoking glow discharge on the inner one of two concentric cylinders proves successful in maintaining constant high potentials

SCIENTIFIC WORTHIES

XXVIII.—SIR ARCHIBALD GEIKIE

SOME MONTHS ago the British Association for the Advancement of Science was holding its annual meeting at Edinburgh under the presidency of Sir Archibald Geikie, F.R.S., Director-General of the Geological Survey of the United Kingdom.

It may well be said that a more appropriate choice could hardly have been made by the Council of the learned Association. Not only is Sir Archibald a thorough Scot, born and educated in Scotland, where he fulfilled for many years the most important duties as a member of the geological staff, and later as a professor in the University of Edinburgh, but, having long been engaged in the supervision of the Scottish Survey, he mapped with his own hand many hundreds of square miles of country, and through the entire scenery of Scotland there is not a single point with the peculiarities of which he did not make himself thoroughly familiar. His knowledge of the ground is not at all restricted to geological relations. In Sir Archibald the qualities of the geologist are combined with those of the enthusiastic lover of landscape, and his able pencil excels in drawing original sketches in which the outlines, peculiar shades, and, one might say, the general spirit of the scenery are fixed with the most striking accuracy. Obviously, therefore he was the right man to be placed at the head of the Edinburgh meeting, which many prominent foreign investigators attended in the hope of afterwards travelling, both as tourists and as men of science, through the most interesting fields of the Highlands. Nobody could have been better fitted to introduce them to the country. When putting Sir Archibald in the chair at Edinburgh, the British Association not only did due justice to one of the most distinguished sons of "modern Athens," it also took the best course to secure from foreign guests the fullest recognition of the various merits of Scotland.

Sir Archibald Geikie was born at Edinburgh in 1838. We learn from a notice in the *Mining Journal* that he was educated at the Royal High School and at the Edinburgh University. When he was only twenty years old he became an assistant on the Geological Survey for Scotland, and proved so able that in 1867, when the Scottish branch of the Survey was made a separate establishment, Sir Roderick Murchison deemed he could not do better than confer the directorial powers on the young assistant whom he had appreciated at work. Four years later, the chair of Geology and Mineralogy at the University having been founded by Sir Roderick with a concurrent endowment by the Crown, Archibald Geikie was invested with the new professorship, which he resigned only at the beginning of 1881, when he was appointed to succeed Sir Andrew C. Ramsay as Director-General of the Geological Survey of the United Kingdom, and Director of the Museum of Practical Geology in Jermyn Street.

That the new Director had not disappointed the hopes he had excited, appeared with sufficient clearness when, some time ago, the Queen conferred on him the honour of knighthood. Now it is our duty to note the chief features of his activity, and to state what personal part Sir Archibald Geikie has played in the recent progress of science. It is scarcely necessary to say that his geological achievements are too important to be conveniently reviewed in a few lines. Nevertheless we shall try to give a general idea of the prominent results to which his name must be attached.

Early appointed, as he was, as an officer of Scotland's Survey, he had, from the beginning, to deal with the most puzzling problems involved in the stratigraphy of the Highlands. The case was a very difficult one, and gave rise to much controversy between Sir Roderick Murchison and many other geologists, among whom it will be sufficient to quote the respected name of Nicol. As in the Highlands gneisses and ordinary crystalline schists were seen resting, with apparent conformity, on Silurian strata, it had been admitted by Murchison that the sequence was a normal one. Therefore the crystalline schists had to be regarded, in spite of their Archæan appearance, as metamorphosed Silurian deposits. Such an assumption had a considerable bearing on other geological problems, as it rendered highly probable the theory that the so-called primitive gneisses were altered sediments, and had nothing to do with the early crust of the molten globe.

That Sir Archibald should at first have taken his Director's side is not at all surprising. But he was never quite satisfied, and his love of truth led him, as soon as he was in a position to do so, to undertake a detailed review of the facts. Since the discovery of Silurian fossils in the rocks of N.W. Sutherland, it had been recognized that the key to the structure of the Scottish Highlands was to be searched for in that region. Accordingly, in the years 1883 and 1884, MM. Peach and Horne were entrusted with a careful study of the Durness and Enboll districts. They were very far from being directed to obtain means of justifying the old survey. "It was a special injunction to the officers" (we quote Geikie's own words) "to divest themselves of any prepossession in favour of published views, and to map the actual facts in entire disregard of theory."

From the work ably carried on by the distinguished surveyors, and verified on the spot by the Director-General, it appeared clearly that Murchison had been deceived by prodigious terrestrial disturbances, of which, at the time, nobody could have formed an idea. Over immense reversed faults, termed *thrust planes* by Geikie and his officers, the older rocks on the upthrow side had been, as it were, pushed horizontally forward, covering much younger sediments, and the displacement attained the almost incredible distance of more than ten miles. Sometimes an outlier of the displaced ground was found capping a hill, while the remainder had been swept away by erosion, and the strangeness of the case led the observer to write, "One almost refuses to believe that the little outlier at the summit does not lie normally on the rocks below it, but on a nearly horizontal fault."

Disturbances of that kind had already been noticed in some coal-basins, as, for example, on the southern limit of the French and Belgian coal-field, where similar outliers had been termed by M. Gosselet "lambeaux de

poussée" But they occurred on a much smaller scale, and there was no reason why the phenomena should be considered otherwise than as quite exceptional To recognize the generality of that class of stratigraphical accidents was a conquest of a high order, not only for Scottish geology, but for all countries where the work of orogenetic disturbances has for a long time suffered from the agencies of erosion The Highlands of Scotland belong to that part of the old European continent which in earlier Palæozoic times emerged from the sea Near the end of the Silurian period it was subjected to enormous pressure, which resulted in folding and breaking the whole border of the dry land, raising in the air a series of high mountainous ridges, the Caledonian chain of M. Suess. But millions of years have since passed over the land, and the continued action of atmospheric powers has left but a very small part of the original mass It is extremely difficult, therefore, to restore the broken continuity, and through the quiet appearance of the now planed ground, the geologist is everywhere bound to search after the scattered signs of previous plication and fracture This is now the task to be fulfilled by the detailed Survey, and every stratigraphical difficulty has to be treated in the newly-acquired light

A few years after that discovery had been made in Scotland, Prof Marcel Bertrand made in Southern France quite similar observations, showing that very limited patches of older formations, which had been till then regarded as remnants of ancient islets, projecting out of younger geological seas, were nothing else than outliers of reversed folds, the remainder of which had disappeared under the action of rain and rivers

In this manner the correction of a long accepted error has led to stratigraphical conclusions of the highest import. In the meantime these gigantic displacements showed themselves accompanied by intense modifications of the rocks, so that Geikie was entitled to write "In exchange for this abandoned belief, we are presented with startling new evidence of regional metamorphism on a colossal scale, and are admitted some way into the secret of the processes whereby it has been produced"

This is not the only occasion on which Sir Archibald has given proof of his readiness to admit frankly and decidedly the correction of opinions which have long been held Some years ago, when the Lower Cambrian fauna had been detected by the officers of the Survey much below the Durness limestone of the Highlands, in a series of strata which rests unconformably on the Torridon sandstone, he was the first to announce the fact before the Geological Society. The "Precambrian," which he had till then been rather reluctant to recognize, has now taken its place in the scale of divisions Moreover, he has created a new name, that of "Dalradian," for the long strip of Precambrian deposits which extends from Donegal to the centre and south-west of Scotland.

As one of the most characteristic formations in Scotland is the Old Red Sandstone, we cannot be surprised that Sir Archibald has devoted much care to the description of the peculiarities of that interesting group of strata. After a long and detailed study of the whole ground, he has summed up his views in some important memoirs, published in the Transactions of the Royal Society of Edinburgh. There he has called again to life the old and long-extinct lakes, where the grits and conglomerates of the Old Red were piled up through the disintegration of surrounding formations, namely, Lake Orcadie, Lake Caledonia, Lake Cheviot, Welsh Lake, and Lake of Lorne, each of them being a separate basin, where the work of sedimentation has been many times interrupted by volcanic outbursts, while in the adjacent and more quiet seas there were accumulated the marine deposits of Devonshire

But the chief work of Sir Archibald seems to be his exhaustive review of the volcanic history of the British Isles. While his brother, Dr James Geikie, the author of "The Great Ice Age," has done excellent service by deciphering the marks of former ice action on the soil of the United Kingdom, Sir Archibald has been particularly attracted by the work of fire, *i e* by the records of that volcanic activity, the evidence of which is so deeply impressed on the scenery of the Hebrides, of Wales, and other districts of Great Britain

The British Isles are now a very quiet ground, where explosive activity and projection of stones seem to be restricted to electoral periods, and although Scotland has been from time to time shaken by minor earthquakes, no human eye has ever seen there any volcanic outburst. Nevertheless, during Tertiary times, immense sheets of lava were poured out in the north-west of the country. To discern the site of the centres of eruption, and determine the old chimneys, the remnants of which give a glimpse into the lowest parts of ascending lavas; to discriminate the volcanic *necks*, the intrusive sheets and dykes, the bedded lavas and the tuffs—this was the first part of the task undertaken by Sir Archibald But it was not enough for him to re-ascend in the past to the beginning of the Tertiary period Not only in the Old Red of Scotland, but in the very heart of the oldest formations known in England and Wales, there were numerous evidences of previous volcanic activity To use Geikie's words "Placed on the edge of a continent and the margin of a great ocean-basin, the site of Britain has lain along that critical border-zone where volcanic energy is more active and continuous"

The chief outlines of that marvellous story, which was hardly suspected some years ago, were recently traced in Geikie's presidential addresses to the Geological Society of London, a work which has been qualified by Mr Iddings, the distinguished American petrographer, as "one of the most important contributions to the history of volcanic action." Nevertheless, it is only a preliminary paper, and in the same manner as he already has devoted a special memoir to the volcanic outbursts of Tertiary times, Sir Archibald promises to publish in a short time a detailed account of the Palæozoic eruptions.

In order to become competent for such an undertaking, the author had prepared himself without sparing time, labour, or trouble Having travelled over much of Europe, from the north of Norway to the Lipari Islands, he was anxious to learn from personal observation the broad features of that American continent, the geological construction of which seems to have been conceived on a much larger scale than that of Europe Therefore in 1878 he rambled over many hundreds of miles in Western America, from the Archæan fields of Canada to the huge volcanic plateaux of Oregon and

Idaho, where a country as large as France and Great Britain combined has been flooded with a continuous sheet of basalt But stratigraphical studies were only part of the necessary initiation Sir Archibald had been one of the first field-geologists in England to perceive the importance of microscopic investigation as an adjunct to field work He might well have left the care of that special study to some officer in the Survey, but he wished to make himself master of the subject. Connected by personal friendship with Zirkel, Renard, and other eminent petrographers, he gave to that branch of the Survey such a vigorous impulse, that upwards of 5000 slices of British rocks were soon prepared and classed in the collections of the museum in Jermyn Street, and if he can now rely with full confidence on his distinguished professional officer, Mr Harris Teall, for any determination of rocks, he himself has won all necessary competence in that department of science, which has been so much enlarged during the last twenty years

An undertaking so ably provided for could not but prove successful It is not, of course, our purpose to give an account of the results arrived at The "History of Volcanic Action in the Area of the British Isles," as it was presented in the presidential addresses for the years 1891 and 1892, is so much condensed that it must be read *in extenso* by every one who takes interest in the matter We would only call attention to the final summary, where some important and far-reaching conclusions are deduced from the observed facts One of them is that British volcanoes have been active in sinking rather than in rising areas, to which it is added that the earlier eruptions of each period were generally more basic, while the later intrusions were more acid

When presenting "a connected narrative of ascertained knowledge regarding the successive epochs of volcanic energy in this country," Sir Archibald did more than write an important chapter of British geology It may be said that he definitively settled the long-controverted question, whether there has been any essential difference or not between the display of volcanic activity at various geological periods Not very long ago some scientific schools—above all, on the Continent—showed the greatest reluctance to admit that true volcanoes could have existed during the Palæozoic era When they were told of Cambrian lavas and felspathic ashes, of Silurian tuffs, especially of Precambrian felsites, they could not restrain a strong feeling of incredulity Against old granitic or porphyritic eruptions they had nothing to object; but the volcanic *facies* appeared to them a privilege restricted to recent geological times To this the present writer might bear personal testimony, as he found his "way of Damas" only when he was fortunate enough to ramble over North Wales, and gather with his own hands pieces of vesicular lava embedded in the tuffs of the Snowdon, or boulders of true felsite lying at the base of the Cambrian series at Llanberis

Not only has Sir Archibald, in common with his countrymen, always escaped that kind of misconception, but he will have contributed more effectively than any other to place the matter in the true light. Thanks to the cliffs of Scotland, he has been able to trace the roots of old volcanoes, to show true volcanic bombs entombed in sediments, and to mark the site round which vast piles of lavas and tuffs, 5000 or 6000 feet in thickness, had been heaped up Likewise, in his previous paper on Tertiary volcanoes, he had established by indisputable sketches that the granitic rocks of the islands of Mull and Skye were ejected during the earlier part of the Tertiary period, and that they belong to the central mass of intrusions, the lateral veins of which have taken the form of granophyres

There is another kind of useful geological work which Sir Archibald has a right to be credited with, we allude to the restoration of the most friendly relations between the official Survey and the Geological Society of London For many years those relations had been maintained at a rather low temperature, both independent geologists and Government's surveyors showed, as it were, more inclination to mutual and severe criticism than to brotherly co-operation This period of misunderstanding is now well over Thanks to the present Director, the Geological Society has more than once received the early flower of the capital results obtained by the Survey, and the recent Presidentship of Sir Archibald has solemnly sanctioned the return of a harmony which will prove of great benefit to the advancement of geological science in England

This is a very brief and imperfect account of the chief work accomplished by the field-geologist, a work which would have been sufficient for the whole of a man's life But we have now to consider in Sir Archibald the master who has been engaged in important educational duties When he was appointed in 1871 to the chair of Geology at Edinburgh he had the whole work of that department to organize, a task which may be wearisome, but which involves great benefit for a man of labour, as he must face every difficulty, and obtain day by day a clear and personal idea of all that is required for teaching To that we are indebted for the undisputed superiority which Sir Archibald has displayed in his "Text-book," as well as in his other educational writings, such as the "Class-Book," a very model of clearness, whereby it has been once more demonstrated that those only are qualified for writing elementary books, who are in the fullest possession of the whole matter Likewise he is the author of small books or "primers" on physical geology and geography, of which some hundreds of thousands of copies have been sold, and which have been translated into most European languages as well as into some Asiatic tongues This exceptional success will be easily understood if we remember that in Sir Archibald's works the traditional barrenness of geology is always smoothed and adorned by a deep and intense feeling for nature Nobody has done more than he to associate geological science with the appreciation of scenery In numberless writings he has undertaken to explain the origin of existing topographical features Among others reference may be made to the volume on "The Scenery of Scotland viewed in connection with its Physical Geology," first published in 1869, of which a new edition appeared in 1887, also to "Geographical Evolution," in the Proceedings of the Royal Geographical Society for 1879, and "On the Origin of the Scenery of the British Isles," published in NATURE (vol. xxix pp 347, 396, 419, 442)

Nevertheless, whatever might have been the attainments of the geologist and of the teacher, they would not have been sufficient to secure universal recognition, had not Sir Archibald been provided in addition with the best powers as a writer From the beginning he was strongly convinced of the importance of cultivating the literary element in scientific exposition, not only in order to make science interesting and intelligible to those outside the circle of actual workers, as he did in writing "Geological Sketches at Home and Abroad," but because he did not admit the right of a man of science to appear before the public without putting on the "nuptial dress" Every one who knows Sir Archibald will readily admit that in doing so he is not impelled by a desire for personal display He is essentially a man of thought as well as of action "*Res non verba*" might well serve him as motto, and whoever has seen his silent but piercing attention in listening to some scientific controversy would never be tempted to suspect him of a wish to search after resounding manifestations But he has too much of the artist's temper to neglect correctness and elegance in the utterance of his thoughts And since nothing in the world is less common than the union of scientific insight and acuteness with a vivid appreciation of nature and a delicate feeling for style, it is not strange that Sir Archibald's fame has passed far beyond the circle of professional men The portrait will be duly completed when it is added that no one could have a better renown for frankness, fair dealing, and perfect trustworthiness in every relation of life

It is highly gratifying for England that the recognition of such achievements has not been left to future times, and that the present generation has not failed in the duty of rewarding so much continuous and fruitful labour He was admitted to the Roya Society before reaching the age of thirty, a most unusual honour, he has been Vice-President, and was recently elected Foreign Secretary, of that Society Since 1890 an Associate of the Berlin Academy, elected by the Royal Society of Sciences at Göttingen, after the death of Studer, the Nestor of Swiss geologists, enrolled among the members of the Imperial Leopold-Caroline German Academy, of the Imperial Society of Naturalists of Moscow, &c, &c, he was chosen in 1891 as a correspondent by the French Academy of Sciences, and in the same year he was made a knight An honorary LL D of the Universities of St Andrews and Edinburgh, he has received the Murchison medal of the Geological Society of London, and twice the MacDougal Brisbane Gold Medal of the Royal Society of Edinburgh has been conferred on him, in recognition of the zeal and skill displayed in explaining the geological peculiarities of his mother-land He is now at the summit of his career, and not so heavily laden with years but that we may express for him the wish *ad multos annos* Let us hope that he will long remain at the head of the distinguished staff to which he has given so profitable an impulse, and continue to serve as a comforting example for those who refuse to acknowledge any other means of genuine success than constant labour and faithfulness to duty

A. DE LAPPARENT

SHAKING THE FOUNDATIONS OF SCIENCE[1]

TO judge by the columns of the daily press, we must expect to find a large number of enterprising company-promoters coming forward shortly to urge, in Parliament and elsewhere, that leave may be given them to confer lasting benefits upon Londoners The good they propose to do comes in the shape of underground intercommunication Locomotives of the ordinary construction, it would seem, are not to be employed, but instead of them cable traction or electric energy in some shape or another On these points, however, we must speak with caution, for we are told that an absence of definite statements and programmes is one of the main features of the pronouncements so far issued

On two previous occasions it has been our duty to draw attention to a scheme, intended to provide more ready means of intercommunication between different parts of London, which threatens to inflict serious damage upon the property of the nation

It so happens that one of the schemes to which reference was made in the opening paragraph is a rehabilitation and expansion of that very project against which we protested on the previous occasion The attempt, which has already once been thwarted, to render the study of the sciences involving exact measurement impossible at South Kensington, is again to be repeated, and it is necessary to warn the public that an enterprise undertaken nominally for their interests, which are, or the moment, regarded as identical with those of the company promoter, will strike a fatal blow at the utility of institutions on which many thousands of pounds of money, public and other, have already been spent, and on which it is in contemplation to spend many thousands more Our protest on the former occasion was based on scientific grounds. There were others strongly urged from other points of view, and as a result of the opposition the scheme was withdrawn for a time

In the shape it now assumes it is still more objectionable, as the scope is now a more ambitious one

Our objection was simply to the route to be followed. In London we have only one locality where telescopes are nightly used by teachers and students, we have only one institution the function of which is limited to physical and chemical teaching and research, where delicate measurements are essential, and form part of the routine work, we have only one institution, the function of which is to teach applied science in the most efficient manner—that is, by teaching in which experiment and observation, and of extreme delicacy, must go hand in hand with the *viva voce* exposition of the professor of each branch of applied science

The contemplated railway proposes to sweep all these away Astronomical Observatories, the various Laboratories of the Royal College of Science, and of the City and Guilds Institute, are not to be considered the least in the world This is practically what it comes to, for we doubt whether either teacher or taught will care to remain in a locality where neither valid experiments nor observations are possible

[1] Continued from vol. xlvi. p 148.

We need not waste time in considering whether some means could not be found to continue to take astronomical photographs of say an hour's exposure, or to use chemical balances of the greatest delicacy, with a railway or tramway of any kind running intermittently within twenty yards of the laboratory in which the work is supposed to be carried on, and it is also clear that the result would be disastrous if the traffic were carried on at any practicable depth.

Last year a joint Committee of the Houses of Lords and Commons fully considered the question as to the principles on which future extensions of what may be called omnibus traffic should be carried on, and they came to the conclusion that electric and cable railways constructed at a considerable depth below the surface would probably be the most convenient means for uniting the various parts of the metropolis more closely.

Some people have attempted to read into this part of the Committee's report that given a cable or electric railway *there will be no shaking!* And it has been suggested that all such opposition as we have expressed above should disappear. This of course is the view of the company-promoter, but it will commend itself to no one else. In fact there are special objections to an electric railway in addition to those earthquakes more or less mitigated which are associated with any system of traction.

No evidence was laid before the Committee as to some of the disadvantages which are incidental to the use of electricity. It is true that these disadvantages are not such as to interfere with the further extension of electrical railways, but they are of sufficient importance to be considered in deciding on the routes which the railways shall follow. Experiments made some little time ago in the neighbourhood of the South London Electrical Railway proved that the electrical disturbances were so great that it was doubtful whether ordinary higher students' work could be carried on within a quarter of a mile.

A quarter of a mile! And the proposed railway, or electric way, or cable way, or tramway is to run within twenty yards of electrical and magnetic laboratories. "*Rien n'est sacré pour un sapeur!*" an evil hidden in the ground ceases to be one.

It must not be forgotten that the interests at stake are not only those of the higher sciences and research. It might, perhaps, be argued that as the instruments used for investigation become more sensitive, and as the necessity for accuracy increases, it may be necessary that researches of a special character should be carried out in places specially selected for their freedom from all external disturbance. A serious damage will, however, be done to our large towns if it becomes necessary for every middle-class youth who wants to master more than the elements of science to become a boarder at a country college. It is frequently complained that there is an increasing separation between class and class, those who are able to do so leaving the towns for the more distant suburbs. It would be a thousand pities if the higher education were also, even in part, to be banished from our great centres of population.

It may be urged by the promoters of the company that it will be easy for them or the Government to plant the Royal College of Science elsewhere, but if the buildings of the College are notoriously inadequate, it was clearly stated at the time when the proposal to place a collection of pictures on the site reserved for science made it necessary to explain the future policy of the Department of Science and Art, that the collections and the laboratories attached to them were in the future to be housed on the plot close to the present site.

But as stated before, it is not necessary only to base our case upon the injury which would certainly be done to the Royal College of Science; it must be remembered that hard by is the City and Guilds Central Institution, in which extensive and costly laboratories, built by the munificence of the City Companies, have during the last few years been filled with students, many of whom are engaged in advanced studies.

Every argument which applies to the one case holds good in the other. The work of the City Companies and the interests of these institutions are endangered in the same way, and for the same reasons, as those of the Government College over the way.

On the previous occasion, when it was proposed to bring a railway at the back of the Central Institution, the Professors there, with the sanction of the City and Guilds of London Institute, opposed the scheme. We understand that the Professors have again made a representation to the Institute which in all probability will result in steps being taken to prevent the construction of any railway or tramway which would interfere with the work carried out in the Physical Department of the Central Institution.

In both these institutions it is as important that the apparatus should be used without let or hindrance from external disturbances, as say, that the reading-room in the British Museum should not be rendered uninhabitable by a nuisance produced either by private individuals or by some company in the neighbourhood.

On these grounds we protest in the name of science against a railway of any kind in Exhibition Road.

If there is one district in the metropolis which ought to be thus secured, it is the neighbourhood of the great national scientific school and its associated collections.

And here a word about these Science Collections. There are philistines among us who think that the collections would do very well without the schools, as the schools could do very well without either higher teaching or research.

There is no doubt a certain advantage to be gained by collecting types of all sorts of apparatus, exhibiting them appropriately labelled in glass cases, through which the public may gaze with, it is to be feared, somewhat indiscriminate admiration; but it must always be recollected that the nation is proud of the British Museum and Art Galleries, not merely because they play a useful part in educating the crowds who visit them, but also because they are centres to which students resort from all parts, not only of the United Kingdom, but of the civilized world, not to gaze at the collections but to *use* them. In like manner a national collection of scientific apparatus should be brought together, not merely to be stared at, but to be used. By an arrangement more logical than those to which our haphazard English

customs too frequently lead, this second object is at present attained

It is almost ludicrous that at the very moment when a Royal Commission is sitting to determine the constitution of a new University for London, Parliament should be asked to sanction a Bill which, if it serves as a precedent, may make the teaching of some of the most important sciences impossible within the metropolitan area Indeed, in this danger we find a new confirmation of the importance of the policy which we have often urged upon those who are directly interested in the constitution of the future University

Science teaching in Exhibition Road is threatened to-day It may be threatened somewhere else to-morrow It will be impossible for a number of competing colleges to defeat the railway engineers, or to preserve intact for scientific research a number of buildings planted upon sites selected without reference to the new danger which has arisen They will be attacked in detail, and beaten one by one How immensely in this, as in many other matters, would their position be strengthened if they were able to speak with one voice in support of a plan decided on in common, and defended together If the hoped-for University of the future already existed, if it spoke with the prestige of the existing University of London, combined with that of the consolidated teaching staffs of the London Colleges, if the support of a Government Department could be asked to aid a University which, like the British Museum, commanded universal respect and support, then it might be possible to obtain a ready hearing for opinions given with all the weight of a great institution of which the country would be justly proud Till the union is effected, which alone will make science in London able to meet its enemies in the gate, we must struggle as best we can to prevent irreparable mischief

We can only hope that the Vice-President of the Council, who is known to have the interests of the higher education at heart, will not allow a railway, electrical or other, to injure the teaching institutions clustered round the magnificent collections of apparatus in his charge

SOUND AND MUSIC

Sound and Music By the Rev J A Zahm, C S C, Professor of Physics in the University of Notre Dame Large octavo, 452 pages (Chicago A C McClurg and Company, 1892)

THIS handsomely got-up and lavishly illustrated volume is, the author informs us, a largely expanded transcript of a course of lectures delivered by him, in 1891 "in the Catholic University of America, at Washington, D C" Its "main purpose is to give musicians and general readers an exact knowledge, based on experiment, of the principles of acoustics, and to present at the same time a brief exposition of the physical basis of musical harmony" A clear intimation is given at the outset (p 18) of the predominant *rôle* which experiment is to play in the acoustical portion of the undertaking. Had Prof Zahm not had at his disposal "all the more delicate and important instruments" of research and verification, in the theory of sound, constructed by Dr Koenig of Paris, he would "not have attempted to give the present lectures on sound" before such an audience as that which actually attended them With Dr Koenig's apparatus around him, however, he had assured means of "entertaining" his hearers, and of "illustrating in a way that would otherwise be impossible the most salient facts and phenomena of sound" The late Isaac Todhunter has deprecated the systematic repetition of perfectly established experiments, on the ground that their results ought to be believed on the statements of a tutor—"probably a clergyman of mature knowledge, recognised ability, and blameless character"—to suspect whom was in itself irrational[1] Prof Zahm's practice pushes to a great length a view directly opposed to that enunciated—with obvious humorous exaggeration—by the well known Cambridge private tutor Not content with a single experiment decisive of each successive issue presented, he performs a whole series bringing into action all the resources of his superbly found collection of acoustical apparatus It is no detraction from the clear and interesting manner in which these formidably numerous experiments are set forth, to say that the amount of space necessarily devoted to explaining the mechanism of the apparatus used gives to parts of Prof Zahm's volume somewhat of the look of an acoustical instrument-maker's illustrated catalogue Subject, however, to this defect, if defect it be, the lectures are decidedly pleasant and attractive reading The illustrations, too, are thoroughly clear and beautifully executed, so that our author may be fairly congratulated on success in 'entertaining'—the word is his own—his hearers and readers His object, to give to general readers an "exact knowledge" of the principles of acoustics, has also been in a fair measure attained, but subject to certain not inconsiderable deductions In describing the processes and results of experiment Prof Zahm is clear and thoroughgoing in expounding the parts of acoustical theory which must be mastered if the facts thus obtained are to be understood in their mutual relations, he is often vague and superficial Thus the nature of wave motion, the formation of stationary undulations, the composition of small vibratory movements—matters of crucial importance to any connected comprehension of Acoustics—receive from him no effective elucidation Nay, he is even chargeable with having, by the misuse of a technical term of perfectly settled meaning, written in a way likely to confuse his readers' ideas on these very matters On p 46 he calls certain points in a series of progressive waves "NODAL points where there is no motion," thus confusing two things which ought to be most carefully distinguished from each other, a point of *momentary* rest in a *progressive wave*, and one of *permanent* rest in a *stationary undulation* The usage which restricts 'node' to this latter meaning is so well established that such use of it as the above is quite inexcusable, especially in an author who himself elsewhere, p 146 &c., employs it in its ordinary signification The same indifference to accuracy of expression recurs in this volume with a frequency not creditable to a professor of an exact science Thus on p 50 the return movement of a prong of a tuning fork is said

[1] "The Conflict of Studies," p 17

to 'pull' air particles apart. On p. 52 we are told that the motions of particles of a water wave "are always at right angles to the direction of the wave itself." On p. 68 the author corrects this statement, but in doing so, takes occasion to speak of a plane "in," instead of 'passing through' the line of progression. On p. 380 he describes harmonic partial-tones as "modifying the quality of their fundamental," though he obviously means the quality of the compound sound due to the fundamental and other partial-tones combined. On p. 387 it is said that the "ratios of frequencies" which characterize particular sounds "are called intervals," and that by dividing one note by another we obtain the intervals between them. Language of this kind is, indeed, hardly misleading, but it is certainly very slipshod.

Before passing from the more generally acoustical, to the more specially musical portion of Prof. Zahm's volume, it is proper to point out one important respect in which it has the advantage over most, or possibly all, the manuals on the same subject which have preceded it. This merit consists in giving a somewhat full account of elaborate experimental researches on beats, combination-tones and quality conducted by Dr. Koenig, the results of which are to a considerable extent at variance with conclusions previously announced by Prof. Helmholtz. In the opinion of our author, Dr. Koenig is "one who, not excepting even the eminent German philosopher just mentioned (Helmholtz), has contributed more than any other person to the advancement of the science of acoustics" (p. 17). A more balanced judgment, while placing great reliance on Dr. Koenig's experimental skill and on the superlative excellence of the apparatus constructed by him, would probably attribute to Helmholtz's opinion a preponderant weight in interpreting and correlating the results of experiment. Be that, however, as it may, Prof. Zahm has done excellent service by popularizing the work so laboriously performed, and so modestly placed on record, by the eminent instrument-maker to whom no one who has put his hand to acoustical work can fail to be under considerable practical obligations.

The specifically musical are decidedly the least meritorious parts of our author's performance. The looseness of phraseology already complained of is here at its worst. On p. 166 we are told that a 'comma,' ($\frac{81}{80}$) is "the smallest interval used in music." A beginner might easily take this to mean that notes differing by only that interval were actually heard consecutively in a musical phrase—of course an absurd supposition. Very misleading, again, is the statement on p. 388 that tones, like major and minor tones, that differ from each other only by a comma "are considered in music to have the same value." The only rational meaning to be got out of it seems to be that *in the equally tempered scale* the distinction between major and minor tones is obliterated. On p. 389 the notes of the diatonic scale, and their relations, in respect to rapidity of vibration "to one another," are set out, and it is added that all but the second and the seventh of the intervals thus indicated are consonant. The essential piece of information, that it is not the intervals formed by these notes with "one another," but with *the tonic*, that are in question, is withheld, and so the reader is left free to suppose *e.g.* that the tritone, F—B, is a consonance. On p. 390 the 'inversion' of intervals is mentioned without any explanation of its meaning.

Attention may well be called to a process of reasoning which occurs on pp. 388-390. Prof. Zahm abruptly introduces (p. 388) calculation by "frequency ratios", assumes, without attempt at proof, that addition of two semitones is performed by squaring the ratio $\frac{16}{15}$, and then remarks (p. 390) "From the foregoing we observe that the sum of two intervals is obtained by multiplying, not by adding their ratios together." An *assumption* in a *particular case* is thus made to do duty as a *general demonstration*.

On p. 396 we read that "so perfectly does the interval of the fifth answer the requirements of the ear that even unpractised singers find it quite natural to take a fifth to a chorus that does not quite suit the pitch of their voice." If, as this passage appears to suggest, practised singers in America find it still more natural to accompany melodies in consecutive fifths, wonderful effects may surely be expected from the choruses to be heard at the Chicago exhibition.

On p. 429 our author describes a diagram by Helmholtz as concerned with the transposition of an interval by an octave, whereas what it really deals with is the enlargement of the interval in question by the addition to it of an octave. On p. 430 he writes down, *as constituents of the chromatic scale of C*, the notes E♯, F♭, B♯ and C♭.

On p. 441, he tells us that in listening to such violin players as Joachim, Wilhelmj, and others "one can always hear distinctly the *Tartini*, or beat-tones, that add such richness and volume to violin music."

To gauge the amount of truth contained in this remark it suffices to bear in mind that in the case of most major, and of all minor consonant chords, Tartini's tones cause a *decided dissonance*. Players who made them 'always distinctly audible' would soon be reduced to permanent inaudibility themselves.

Prof. Zahm's volume is creditably free from misprints; the following have, however, been noted:

P. 23, l. 16 'period' for 'periods.'
P. 68, l. 21 'amplitude' for 'amplitudes.'
P. 90, l. 8 'Ajugari' for 'Agujari.'
P. 142, in diagram, B_4♯ for B_4.
P. 152, in diagram I, D♯ for B.
P. 388, ll. 11 and 12, G for F.

GERLAND'S ETHNOLOGICAL ATLAS

Atlas der Volkerkunde. (Berghaus' Physikalischer Atlas, Abth. vii.). Bearbeitet von Dr. Georg Gerland, Professor a. d. Universitat in Strassburg. (Gotha: Perthes, 1892.)

ANTHROPOLOGY owes much to Prof. Gerland, whose completion of the two last volumes of the late Prof. Waitz's "Anthropologie der Naturvolker" is a monument of that co-ordinated knowledge of fact which is the source of sound principle. His new "Atlas of Ethnology," while forming part of the great Physical Atlas of Berghaus, may be obtained and used as a separate work by anthro-

pologists, to whom it will be of great service in methodizing the vast and growing information with which they have to deal This application of graphical method, it is true, has difficulties which even the greatest skill cannot altogether overcome, but Prof Gerland may well be content with his success in making evident at a glance the characteristics of mankind, seen from many points of view Their distribution over the earth, as thus made evident, may often lead straight on into theories of origin The fifteen plates contain nearly fifty maps, each suggesting a principle, or showing where there is room for one

Plate I. represents on two planiglobes the classification of human races as to skin and hair Prof Gerland does not even combine these two characteristics, and points out in his introductory remarks that any attempt to map out man into defined physical races is impossible, for such division does not exist in nature Anthropologists of course know this, but care is not always taken to make it clear that race-types are not so much complete realities as statistical abstractions from partial realities, the various measurable characters of skull, limbs, complexion, hair-form, &c , combining and blending too intricately for absolute definition I was struck by meeting lately in a popular book with a confident mention of the four distinct Aryan race-types, and it occurred to me that it would bring the statement down to its bearings to put one of Prof Gerland's planiglobes before the author, desiring him to define and map out these varieties of mankind Even in Gerland's broad general distinctions of complexion and hair, an anthropologist not thoroughly special on the anatomical side may find novelty and difficulty The opinion that all native Americans are similar as to race is here strongly and probably with reason modified by the native Brazilians being separated on the complexion-map from other peoples of North and South America, and placed to match the Tartars and Chinese What amount of evidence there is for placing the Berbers of North Africa under the same map-colour seems not so clear, but it is to be noticed that the same tint includes several more or less distinct grades in Broca's scale An attempt is even made to separate the friz-haired negroids into classes according to the arrangement of their corkscrew-tufts of hair on the skin Plate III , in two maps, classifies man according to his religious beliefs and customs, and here the prevalence of special rites offers instructive generalizations Thus the American line which limits the smoking of tobacco as a religious ceremony, indicates the spread of this peculiar rite from some religious centre over an enormous area No doubt it is rooted in nature, from the fact that its narcotic ecstasy brought the priest into direct visionary contact with the spirit-world But none the less, it proves the religions of savage tribes, separated by great distances on the map, to be bound together by historical connexion Not less remarkable is the compactness of the districts of Eastern Asia and the opposite Continent of America, where masks are used, apparently originally with religious significance Here again it is evident that we have to do not merely with independent growth from the human mind, but in some way with historical transmission It must be remembered in using these maps, that they bind their author only to fact, and not to theoretical interpretation This same plate maps out the immense districts whose natives have a myth of a deluge, the upheaving of the earth, &c , but it cannot distinguish in North and South America, for instance, between regions where deluge-myths are old, and those where they were introduced by the Jesuits a few generations ago Plate IV , mapping out regions liable to special diseases, as malarious fevers, pestilence, cholera, yaws, &c , contains in a condensed form a vast collection of knowledge, bearing on anthropological arguments as to the relation of race to physical constitution, and thus opening into one of the great problems of the history of man Plate V classes out the varieties of human food, clothing, dwellings and occupations Plate VI and onward map out the distribution of nations and tribes at different periods as known to history, Plate XIV being devoted to the distribution of languages over the world

Anthropologists who keep this atlas at hand as a help in their work will by practice find out its merits and defects The representation of the geographical distribution of arts and customs has long been a feature of the Pitt-Rivers Museum, where so far as possible each series, illustrating development and transmission of culture, is accompanied by a small world map coloured to show the parts of the world it occupies It is of course impossible to Prof Gerland to work in such detail, involving as it would do hundreds of separate charts He has to indicate his distributions on a moderate number of plates and mostly uses planiglobes, a projection which, after being neglected for generations, will, in its improved modern arrangement, certainly come into more general favour On these, by ingenious devices of tinted patches and streaks, combined with lines and dots, he succeeds in giving a more general survey of man and civilization than our students have ever had in their hands before EDWARD B TYLOR

OUR BOOK SHELF

Castorologia, or, The History and Traditions of the Canadian Beaver By Horace Martin, F Z S (London. Stanford, 1892)

"BEAVER" was once the most important fur in the world In former days the pelt of this Rodent was the standard by which all barter in the Dominion of Canada was regulated, and "beaver" passed as current coin throughout the whole of North America Even now the quantity of beaver skins brought to England is considerable Mr Poland, in his "Fur bearing Animals," tells us that upwards of 63,000 beaver skins were sold by the Hudson's Bay Company in 1891 But "beaver hats" formerly required a much larger supply than this, and in 1743 it is said that 127,000 beaver-skins were imported into La Rochelle alone Our "top" hats are now made of silk, and beaver has become a fur of second-rate importance

Besides the fur of the beaver many other points of interest attached to this animal will be found discussed more or less completely in Mr Martin's volume Long before its fur was required for hats *castoreum* or castorin—a substance found in two large glands, situated near the base of the beaver's tail—was a much-valued specific in medicine, as spoken of by Hippocrates and Pliny. Even at the present time its use is by no means abandoned, and the "crude article" is "still sold at our drugstores" at prices varying "from eight to ten dollars a

pound" But in past centuries castoreum was considered a sovereign remedy for every kind of disease Many amusing details on this part of the subject are given by Mr. Martin, mostly extracted from the "Castorologia" of Johannes Francus, published in 1685 The wisdom of Solomon himself is attributed by this learned author to the virtues of the beaver To acquire it, it is only necessary "to wear a hat of beaver's skin, to rub the head and spine with that animal's oil, and to take twice a year the weight of a gold crown piece of castoreum"

At the end of his volume Mr Martin places a short account by Mr C V Riley, the well known American entomologist, of *Platypsillus castoris*, a parasite on the beaver, and one of the most remarkable among the many extraordinary forms of parasitic insects Mr Riley correctly refers this creature to the coleoptera, although other naturalists, and, amongst others, its discoverer, Ritsema, have expressed different views on this point He omits, however, to refer to the excellent account of *Platypsillus castoris*, written by the late John Leconte, and published in the Proceedings of the Zoological Society of London for 1872 Dr Leconte has here shown that it is necessary to make a special family (Platypsillidæ) for the reception of this curious parasite, but that it must be unquestionably referred to the coleoptera

On account of these and other peculiarities the beaver is unquestionably an animal of great general interest, and Mr Martin has done well to devote a volume to what is evidently his favourite theme There is, we must allow, little, if anything, original in it, and the statements on scientific points cannot always be implicitly depended upon But the author has brought together a large amount of information on the subject, and his book is "popularly written" and "fully illustrated," though we cannot quite agree to his claims to have produced an "exhaustive monograph"

An Atlas of Astronomy By Sir Robert Stawell Ball, LL.D, F R S (London George Philip and Son, 1892)

A NEW book by Sir Robert Ball is always a matter of interest, but the present one naturally lacks the usual characteristics It is described as "a series of 72 plates with introduction and index" In addition to monthly and general maps of the stars, the atlas reproduces pictures of the sun, moon, planets, and comets, and contains diagrams illustrating their motions and dimensions As the book is chiefly meant to be a companion to more general works, the introductory matter is purposely brief, but still it has several features of interest Special attention may be drawn to the excellent description of a simple graphical method of determining the orbit of a binary star

To the serious student who may possess a small telescope the new atlas will be very useful Here he may learn how to determine the positions of sun spots, how to find the places occupied by the various planets, and what objects are most likely to be within reach of his instrument. Those interested in selenography will derive much assistance from the twelve plates showing the moon at different phases, which have been specially drawn by Mr Eiger, each being accompanied by an index map One can only wonder, however, that some of the recent excellent photographs of the moon have not been pressed into the service

The star maps, on the whole, are excellent, and our only complaint is of the excessive density of the Milky Way, which, in some parts of the maps, is almost sufficient to obliterate the names and numbers of the stars The monthly maps will be particularly useful to those who are just learning the constellations, a new feature being a belt indicating the track of the planets

Spectroscopic astronomy is entirely omitted, the author being of opinion that this great branch of work can only receive justice in a separate atlas In this we heartily agree, and trust that such an atlas will soon be forthcoming

The author's large following of readers will no doubt welcome the new comer, but we must express regret that astronomical photographs are not more fully represented It would be interesting, for example, to reproduce a series of photographs of typical nebulæ, all of which, we believe, are now available A plate showing the advantages of photography in the delineation of stars would also add to the interest of the atlas

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Vector Analysis

I FANCIED that, in reply to the voluminous letters of Prof Willard Gibbs (NATURE, xliii 511, xliv 79), I had said in a few words all that is requisite (if, indeed anything *be* requisite) to show the necessary impotence, as well as the inevitable unwieldiness, of every system of (so-called) *Vector Analysis* which does not recognize as its most important feature the product (or the quotient) of two vectors — *i e* a Quaternion

A recent perusal of the first four pages of a memoir by Mr O Heaviside (*Phil Trans* 1892) —for so far only could I go —has dispelled the illusion For he calls the correspondence just spoken of a "rather one sided discussion" —a truly Delphic delivery —cleared up, however, by what follows it I particularly desired to read the memoir (which the Author had kindly sent me) as I hoped to learn from it something new in Electrodynamics But, on the fifth page, I met the check-taker as it were —and found that I must pay before I could go further I found that I should not only have to unlearn Quaternions (in whose disfavour much is said) but also to learn a new and most uncouth parody of notations long familiar to me, so I had to relinquish the attempt In the last of the four pages of my progress, I had found that Mr Heaviside (though, as above stated, he has a system of his own) is an admirer of Prof Gibbs' system, to such an extent at least that he thinks "his treatment of the linear vector operator specially deserving of notice" There I was content to leave the matter

But Mr Heaviside has just published (*Electrician*, 9/12/92) an elaborate attack on Quaternions, of a kind which is calculated to do real injury to beginners In answer to his remarks, in which he continues to point to me as the persistent advocate of a system which all right-minded physicists should avoid, I would simply refer him (and his readers, if there be such) to a brief Address which I gave a short time ago to the Physical Society of Edinburgh University (*Phil Mag* Jan. 1890) One or two sentences, alone, I will quote here :—

"if we can find a language which secures, to an unparalleled extent, compactness and elegance, and at the same time is transcendently expressive—bearing its full meaning on its face—it is surely foolish, at least, not to make habitual use of it"

"For (Hamilton) the most complex trains of formulæ, of the most artificial kind, had no secrets —he was one of the very few who could afford to dispense with simplifications yet, when he had tried quaternions, he threw over all other methods in their favour, devoting almost exclusively to their development the last twenty years of an exceedingly active life"

The main object, however, of my present letter, is to call attention to a paper by Dr Knott, recently read before the Royal Society of Edinburgh Dr Knott has actually had the courage to *read* the pamphlets of Gibbs and Heaviside, and, after an arduous journey through these trackless jungles, has emerged a more resolute supporter of Quaternions than when he entered. He has revealed the (from me at least) hitherto hidden mysteries of the Dyadic, and of Prof Gibbs' strange symbols Pot, Lap, Max, New, &c. The first turns out to be only the linear and vector function ; and the others are merely more or less distressing symptoms characteristic of imperfect digestion or assimilation of ∇. And when, at my request, Dr. Knott

translated into intelligible form the various terms of one of the less formidable formulæ of Mr Heaviside's memoir, I was surprized to find two old and very unpretending friends masquerading in one person like a pantomime Blunderbore In one of his Avatars the monster contains, besides the enclosing brackets, no fewer than 24 letters, 12 suffixes, 3 points, and 5 signs! When he next appears he has still the brackets to hold him together, but although he has now only 18 letters, he makes up his full tale of 44 (or 46) symbols, for he has 9 suffixes, 3 indices, 3 points, 5 signs, and 3 *pairs* of parentheses! I used to know him as compounded of 14 separate marks only, viz — $V^2\nabla\sigma + 2S\nabla\nabla_1 S\sigma\sigma_1$, but, unless I had required to dissect him, I should never have put him in anything resembling his new guise

Dr Knott's paper is, throughout, interesting and instructive —it is a complete exposure of the pretensions and defects of the (so-called) Vector Systems "Wer diesen Schleier hebt soll Wahrheit schauen!" I find it difficult to decide whether the impression its revelations have left on me is that of mere amused disappointment, or of mingled astonishment and pity

Edinburgh, 24/12/92

Measurement of Distances of Binary Stars

WITH reference to Mr. C E Stromeyer's letter on the above subject, which appeared on p 199, it may be of interest to point out that his plan of determining the distance of a binary star is by no means a new one

The method was, I think, first suggested by Mr Fox Talbot at the Edinburgh meeting of the British Association in 1871, but the mere idea was sufficiently obvious as soon as the possibility of determining velocities by the spectroscope had been demonstrated by Dr Huggins

The first discussion of the geometrical conditions of the problem was given by Prof C Niven in the *Monthly Notices*, vol xxxiv No 7, where he exhibits the relation connecting the parallax, the relative velocity, and the elements of the orbit of a double star, and computes the value of the product (πV) of the parallax and velocity for a small number of binary systems

In a paper published in the Proceedings of the Royal Irish Academy for May, 1886, I examined the same question from a slightly different point of view, being at the time unaware of Prof Niven's paper, and was led to similar results An epitome of this paper was published in your Astronomical Column, vol xxxiv p 206 From the results obtained it appeared that, all things considered, γ Coronæ Australis and α Centauri were the most likely binaries to yield to this method of eliciting the secret of their parallax, while α-Geminorum, one of the stars selected by Mr Stromeyer, was shown to be most unfavourable on account of the situation of its orbit

In the *Monthly Notices* for March, 1890, I again drew attention to the subject in view of the accuracy of the results obtained by the photographic method in the hands of Prof Pickering and Prof Vogel In this paper I gave an extended list of binaries with the usual geometrical and dynamical elements, and in addition the two elements A and B on which the relative velocity depends I also gave the greatest value which πV can attain in each case and the velocity to be expected in the case of those stars whose parallaxes had been determined

Again in Mr J E Gore's valuable catalogue of Binary Star Orbits, published in the Proceedings of the Royal Irish Academy for June, 1890, columns 18 and 19 are devoted to the constants A and B computed from my formulæ (which I may say ought more properly to be called Prof Niven's formulæ on account of the priority of his paper) for eighty-one different orbits

The subject has also been discussed by Miss Clerke in "The System of the Stars," pp 199-201, where references to most of the original publications will be found

I may perhaps add that the inverse problem of determining the elements of the orbit from spectroscopic observations alone has also been investigated by me in the *Monthly Notices*, vol li, No. 5, where I have deduced the principal elements of the orbit of β Aurigæ, a spectroscopic double which no telescope can divide

I have been disappointed that astronomers engaged on spectroscopic determinations of stellar velocities have not devoted more attention to observations of already known binaries, which appear to me to offer a promising field of work, and have often regretted that at this observatory we have not the means of undertaking the investigation, and if Mr Stromeyer's letter has no other effect than to bring the subject once more forward it will have done good service, but I should like to point out that the second of the stars selected by him ought on no account to be taken as a test of the feasibility of the method, since the accurate discussion of the conditions shows that unless this is an exceptionally remote system the velocity must be very small indeed For instance, assuming Johnson's parallax, viz 0″ 20, the relative velocity of the components amounted last year to only 0 6 miles per second.

In the northern hemisphere the most favourably situated binaries are 70 Ophiuchi, ξ Ursæ Majoris, and, if Peters' orbit represents the real motion of the pair, 61 Cygni, while for the southern hemisphere special attention ought to be directed to α Centauri and γ Coronæ Australis

In Mr Gore's Catalogue, referred to above, will be found all the materials for determining when to observe any known binary most favourably in this respect, and for deducing its parallax from the measures obtained, and it ought to be borne in mind before letting the subject sink back once more into oblivion, that, other things being equal, this method is most likely to succeed in the case of the most distant systems, where the parallax is so small that the ordinary trigonometrical method necessarily fails us, and that when the micrometer, the heliometer, and the stellar photograph break down, the spectroscope will sound the further depths with ever increasing facility

December Meteors (Geminids)

THESE meteors were moderately abundant on the night of December 12, which appears to have been a very favourable one in regard to weather The chief radiant point was observed in the normal position very close to α Geminorum, and there was a strong contemporary shower from a centre east of β Geminorum

At 10h 10m December 12, a fireball estimated to be twice as brilliant as Venus was observed by Mr Booth at Leeds It moved rather slowly from $150°+43°$ to $188°+41°$, and divided into two pieces at the finish

Mr Wm Burrows, of Small Lane, Ormskirk, writes to me with reference to a meteorite which he observed to fall at a later hour on the same night He says the time was 6 52 a.m (December 13), and refers to the phenomenon as follows:— "Seeing the meteor was coming to the earth I crossed the road to where it appeared to be falling, and it fell about two yards from me When it struck the earth it made a noise like the report of a gun, it also went black instantly While descending it had a tail of fire about a foot long It is 1¾ inch in diameter one way, and 1¼ inch another, and one inch thick"

Mr Burrows sends drawings of the object, and it being still in his possession it is hoped the matter may be suitably investigated Should it prove a veritable meteorite one interesting circumstance in connection with it will be that its descent took place concurrently with the shower of Geminids

It is significant that December 9–13 constitutes a well-defined ærolitic epoch, rendered memorable by the fall at Wold Cottage, Thwing, Yorkshire, on December 13, 1795, and by many others, such as that at Massing, Bavaria, December 13, 1803, at Weston, Connecticut, U S.A, December 14, 1807, at Wiborg, Finland, December 13, 1813, at Ausson, France, December 9, 1858, at Baudong, Java, December 10, 1871, &c

Bristol, January 1 W F DENNING

The Earth's Age

As Dr Wallace (NATURE, p 175) trusts "that on further consideration" I shall "admit that" my "objection is invalid," it is evident that I have failed to make clear to him my argument showing that his data do not warrant his conclusion

He overlooks the fact that a thickness of 177,200 feet of sedimentary rocks is, standing alone, a perfectly indefinite quantity, to make it definite it must have a definite area.

As he mentions no area for it we are justified in assuming that he means the land area of the globe, whereas his calculation is made as though area were not of the essence of the problem, in short, as if the formation of a pile of sediment 177,200 feet thick, of no matter what area, were the problem

In Sir A Geikie's calculation and all other similar ones with which I am acquainted, the thickness of the sedimentary rocks is tacitly assumed to be their thickness all over the land area of the globe

Dr Wallace's calculation leads to the absurd result that continents are growing nineteen times as fast as materials are produced to supply their growth

Leaving the question of the conclusions to which Dr Wallace's data logically lead, I may say that I am not responsible, and do not hold him to be responsible, for the absurd theory as to the thickness of sedimentary rocks on which they are based

In order to arrive at a scientifically accurate result, what we require to know is the present actual thickness in every part of the world, plus all the thickness which has previously existed in, but since been denuded away from, every area The existing thickness in geologically explored areas can perhaps be ascertained within certain limits of error from geological maps and memoirs For instance where the surface consists of Torridon Sandstone overlying Archæan gneiss of igneous origin, the thickness of sedimentary rock is that of the Torridon Sandstone only, if we assume that the gneiss there is part of the metamorphosed original crust of the earth, for the existence of which Rosenbusch has recently argued

It is easily demonstrable, first, that in many places the existing thickness of each formation, where undenuded, is far from being the maximum thickness, and, secondly, from the thinning out in some directions, or merging, near the old shoreline, into conglomerates, that some formations were never deposited over certain areas, indeed, the very existence of a sedimentary deposit necessarily implies that of land undergoing denudation and not receiving deposit, although it may well be doubted whether the land area was always nineteen times the area receiving deposit

Reasoning from the deposits preserved as to those removed by denudation, it is highly improbable that any considerable area ever received either the complete series of deposits, or on the average anything like the maximum thickness of the deposits it actually received In addition to this, some formations usually considered to be successive may be really contemporaneous, so that the figures representing maximum thicknesses usually taken in calculating the earth's age are probably far above the truth for the purpose in question

The immense labour involved in calculating the existing thickness of sedimentary rocks in each area, and the thickness which there is any reasonable ground for supposing to have been at any time denuded from that area, as well as the uncertainty of the results, has probably deterred geologists from attempting the task, especially as large areas are very imperfectly known BERNARD HOBSON

Tapton Elms, Sheffield, December 24

THE first part of Mr Hobson's letter alone requires notice from me, as the latter part characterizes as absurd the views of those eminent geologists who have estimated the total thickness of the sedimentary rocks, and seems to assume that such writers as the late Dr Croll and Sir Andrew Ramsay overlooked the very obvious considerations he sets forth

As regards myself, he reiterates the statement that when geologists have estimated the total thickness of the sedimentary rocks at 177,200 feet, they mean that this amount of sediment has covered the whole land surface of the globe, that, for example, the coal measures, the lias, the chalk, the greensand, the London clay, &c, &c, were each deposited over the whole of the continents, since it is by adding together the thicknesses of these and all other strata that the figure 177,200 feet (equal to 33 miles) has been obtained

Mr Hobson concludes with what he seems to think is a *reductio ad absurdum* —"Dr Wallace's calculation leads to the absurd result that continents are growing nineteen times as fast as materials are produced to supply their growth"

But the apparent absurdity arises from the absence of any definition of the "growth of continents," and also from supposing that the growth of continents is the problem under discussion The question is, as to the growth in thickness, of sedimentary deposits such as those which form the geological series These deposits are each laid down on an area very much smaller than the whole surface of the continent from the denudation of which they are formed They are therefore necessarily very much thicker than the average thickness of the denuded layer and the ratio of the area of denudation to the area of deposition which I have estimated at 19 to 1, gives their proportionate thickness If Mr Hobson still maintains that he is right, he can only prove it by adducing *evidence* that every component of the series of sedimentary rocks has once covered the whole land surface of the globe, not by assuming that it has done so, and characterizing the teaching of all geologists to the contrary as absurd ALFRED R WALLACE

Ancient Ice Ages

MR READE in his letter (NATURE, p 174) refers to the striations on the pebbles forming the conglomerates at Abberley and the Clent Hills

Following the late Sir Andrew Ramsay, he considers the deposits to be of glacial origin, but goes further than that distinguished geologist in citing them as proof of a former ice age

It is but reasonable to suppose that *glaciers* existed in past ages in places where the conditions—such as high altitude and abundant precipitation—were favourable

Before, however, the existence of a former *glacial period* can be established, we must have evidence of contemporaneous deposits of undoubtedly glacial origin, and extending over wide spread areas—say half a hemisphere J LOMAS

University College, Liverpool, December 31

Printing Mathematics

THE use of the solidus in printing fractions has been advocated by authorities of such weight that it seems almost a heresy to call it into question Yet I venture to think that there is a good deal to be said against it In such matters the course preferred by mathematical writers and their printers is apt to take precedence over that which is most convenient for the great body of those who will read their work. It is tacitly assumed by those who prefer this notation that the getting of mathematical formulæ into line with ordinary printing is an unmixed advantage No doubt it is easier to set up the work in type thus, but with the consequent rapidity and cheapness of printing the advantage ends Most people will agree that it is much pleasanter to read a mathematical book in which the letterpress is well spaced, so that the formulæ stand out clearly from the explanatory language, than one in which the two run together in an unbroken stream just as a book divided into paragraphs is more readable than one which is not The old style is more restful to the mind and eye and one can more readily pick out the salient features of the demonstration

Another aspect of the question seems to me more important In making any calculation mentally it is much easier to visualize fractions, more especially if complicated, as written in the ordinary way than as written with the new fashioned notation The component parts of the mental picture are imagined as spread over a plane instead of being arranged along a line, and can be thought of separately with less confusion From a similar point of view it will be admitted that it is inconvenient to write mathematical expressions in one form and to print them in another

Then, again, I doubt whether the assumption that the solidus notation conduces to accuracy is justified No doubt the printer makes fewer original errors, but whereas with the old notation his frequent glaring errors are more readily detected by the proof-reader (or, if missed by him, by the ordinary reader), with the new notation the misplacement or omission of a solidus is, from the simplicity of the error, likely to be overlooked. In general, no one will be the poorer if a little more trouble is taken with the printing, and a little more paper is used for the book

The symbol / has advantages over its equivalent , and to its restricted use, such as is made by Sir G Stokes, one can hardly object, it matters little how such expressions as a/b or dy/dx are printed But it is the thin end of the wedge, and one is under a debt of gratitude to Mr Cassie for showing, in your issue of November 3, to what it may lead May it be a long time before we have to learn to substitute for the harmless expression, $\frac{b^{\frac{1}{2}}}{c(d+e)^3}$ its newest equivalent, $\{b \backslash 1/2\}/\{c\{d+e\} \backslash 3\}!$ I trust that no one will interpret the final note of exclamation as a factorial symbol M J JACKSON

The Teaching of Botany

I do not think there is at present any book in English giving practical instructions for experiments in Physiological Botany There is, however, an excellent book of this kind in German, Dr W Detmer's "Das pflanzen physiologische Praktikum," published by Gustav Fischer, Jena, 1888 This, no doubt, contains all that your correspondent "A H" (NATURE, *ante*, p 151) requires, though it is perhaps somewhat more advanced than is necessary for school teaching D H SCOTT

Old Palace, Richmond, Surrey

THE ORIGIN OF THE YEAR[1]

IV

THE reformation of the Egyptian calendar, to be gathered, as I suggested in my last article, from the decree of Tanis, is not, however, the point to which reference is generally made in connection with the decree The attempt recorded by it to get rid of the vague year is generally dwelt on

Although the system of reckoning which was based on the vague year had advantages with which it has not been sufficiently credited, undoubtedly it had its drawbacks

The tetramenes, with their special symbolism of flood, seed, and harvest time, had apparently all meant each in turn, however, the meanings of the signs were changed, the "winter season" occurred in this way in the height of summer, the "sowing time" when the whole land was inundated, and there was no land to plant, and so on Each festival, too, swept through the year Still, it is quite certain that information was given by the priests each year in advance, so that agriculture did not suffer, for if this had not been done, the system, instead of dying hard, as it did, would have been abolished thousands of years before

Before I proceed to state shortly what happened with regard to the fixing of the year, it will be convenient here to state a suggestion that has occurred to me, on astronomical grounds, with regard to the initial change of gn

It is to be noted that in the old tables of the months, instead of Sirius leading the year, we have Teχi with the two eathers of Amen In later times this is changed to Sirius

I believe it is generally acknowledged that the month tables at the Ramesseum is the oldest one we have, there is a variant at Edfu They both run as follows, and no doubt they had their origin when a 1st Thoth coincided with an heliacal rising and Nile flood

Egyptian month	Tropical month	Ramesseum	Edfu
Thoth	June–July	Teχi	Teχ
Phaophi	July–Aug	Ptah (Ptah-res-aneb-f)	Ptah (Menχ)
Athyr	Aug–Sep	Hathor	?
Choiak	Sep–Oct	Paχt	Kehek
Tybi	Oct–Nov	Min	Set but
Mechir	Nov–Dec	Jackal (rekh-ur)	Hippopotamus (rekhur)
Phamenoth	Dec–Jan	,, (rekh-netches)	Hippopotamus (rekh netches)
Pharmuthi	Jan–Feb	Rennuti	Renen
Pachon	Feb–Mar	χensu	χensu
Payni	Mar.–Ap	Horus (χonti)	Horus (Hor-χent χati)
Epiphi	Ap–May	Âpet	Âpet
Mesori	May–June	Horus (Hor m-χut)	Horus (Hor-ra-m-χut)

I am informed that Teχi, in the above month-list, has some relation to Thoth In the early month-list the goddess is represented with the two feathers of Amen, and in this early stage I fancy we can recognize her as Amen-t, but in later copies of the table the symbol is changed to that of *Sirius* This, then, looks like a change of cult depending upon the introduction of a new star—that is, a star indicating by its heliacal rising the Nile rise after the one first used had become useless for such a purpose

I have said that the Ramesseum month list is probably the oldest one we have It is considered by some to date only from Ramses II, and to indicate a fixed year, such, however, is not Krall's opinion[1] He writes —

"The latest investigations of Dumichen show that the calendar of Medinet Abu is only a copy of the original composed under Ramses II about 120 years before

"But the true original of the calendar of Medinet-Abu does not even date from the time of Ramses II It is known to every Egyptologist how little the time of the Ramessids produced what was truly original, how much just this time restricted itself to a reproduction of the traditions of previous generations In the calendar of Medinet-Abu we have (p 48) not a fixed year instituted under Ramses II, but the normal year of the old time, the vague year, as it was, to use Dschewhari's words quoted above (p 852), in the first year of its institution, the year as it was before the Egyptians had made two unwelcome observations First, that the year of 365 days did not correspond to the reality, but shifted by one day in four years with regard to the seasons, secondly—which of course took a much longer time—that the rising of Sirius ceased to coincide with the beginning of the Nile flood

"We are led to the same conclusion by a consideration of the festivals given in the calendar of Medinet-Abu They are almost without exception the festivals which we have found in our previous investigation of the calendars of Esne and Edfu to be attached to the same days. We know already the Uaga festival of the 17th and 18th Thoth, the festival of Hermes of the 19th Thoth, the great feast of Amen beginning on the 19th Paophi, the Osiris festivals of the last decade of Choiak, and that of the coronation of Horus on the 1st Tybi

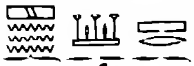
"Festivals somehow differing from the ancient traditions, and general usage are unknown in the calendar of Medinet-Abu, and it is just such festivals which have enabled us to trace fixed years in the calendars of Edfu and Esne

"We are as little justified in considering the mythologico-astronomical representations and inscriptions on the graves of the time of the Ramessids as founded on a fixed year, as we can do this in the case of the Medinet-Abu calendar In this the astronomical element of the calendar is quite overgrown by the mythological Not only was the daily and yearly course of the sun a most important event for the Egyptian astronomer, but the priest also had in his sacred books many mythological records concerning the god Râ, which had to be taken into account in these representations The mythological ideas dated from the oldest periods of Egyptian history, we shall, therefore, be obliged for their explanation not to remain in the 13th or 14th century before Christ, but to ascend into previous centuries, *I should think about the middle of the fourth millennium before Christ, that is the time at which the true original of the Medinet-Abu calendar was framed* Further we must in these mythological and astronomical representations not overlook the fact that we cannot expect them to show mathematical accuracy—that, on the contrary, if that is a consideration, we must proceed with the greatest caution We know now how inexact were the representations and texts of tombs, especially where the Egyptian artist could suppose that no human eye would inspect his work, we also know how often representations stop short for want of room, and how much the contents were mutilated for the sake of symmetry"

[1] Continued from p. 35

[1] *Op cit* p 48.

There is also, as I have indicated, temple evidence that Sirius was not the first star utilized as a herald of sunrise We have then this possibility to explain the variation from the true meaning of the signs in Ramessid times



Pre-Sirian Text: Thoth, Phaophi, Athyr, Choiak | Tybi, Mechir, Phamenoth, Pharmuthi | Pachons, Payni | Epiphi, Mesori

Sirian, 3192 B C: Thoth, Phaophi, Athyr, Choiak, Tybi, Mechir, Phamenoth, Pharmuthi, Pachons, Payni, Epiphi, Mesori

And it may be gathered from this that the Calendar was reorganized[1] when the Sirius worship came in and that the change effected in 619 B C brought the hieroglyphic signs back to their natural meaning and first use

Before I pass on it may be convenient in connection with the above month-tables to refer in the briefest way to the mythology relating to the yearly movement of the sun, in order to show that when this question is considered at all, if it helps us with regard to the mythology connected with the rising and setting of stars, it will as assuredly help us with regard to the mythology of the various changes which occur throughout the year

We have, as we have seen, in the Egyptian year really the prototype of our own The Egyptians, thousands of years ago, had an almost perfect year containing twelve months, but instead of four seasons they had three, the time of the sowing, the time of the harvest, and the time of the inundation Unfortunately, at various times in Egyptian history, the symbols for the tetramenes seem to have got changed

The above-given inscriptions show that they had a distinct symbolism for each of the months Gods or goddesses are given for ten months out of the twelve, and where we have not these, we have the hippopotamus (or the pig) and the jackal, two circumpolar constellations I think there is no question that we are dealing here with these constellations, though the figures have been supposed to represent something quite different

There are also myths and symbols of the twelve changes during the twelve hours of the day, the sun being figured as a child at rising, as an old man when setting in the evening These ideas were also transferred to the annual motion of the sun In Macrobius, as quoted by Krall, we find the statement that the Egyptians compared the yearly course of the sun also with the phases of human life

Little child	=	Winter solstice
Young man	=	Spring equinox
Bearded man	=	Summer solstice
Old man	=	Autumnal equinox

With the day of the summer solstice the sun reaches the greatest northern rising amplitude, and at the winter solstice its greatest southern amplitude. By the solstices the year is divided into two approximately equal parts, during the one the points of rising move southwards, during the other northwards

This phenomenon, it is stated, was symbolized by the two eyes of Rā, the so-called Utchats, which look in different directions They appear as representing the sun in the two halves of the year

We have next to discuss the fixed year, to which the Egyptian chronologists were finally driven in later Egyptian times

The decree of Tanis was the true precursor of the Julian correction of the calendar In consequence of this correction *we* now add a day every four years to the end of February The decree regulated the addition, by the Egyptians, of a day every four years by adding a day to the epacts, which were thus 6 every four years instead of being always 5 as they had been before

In fact it replaced the vague year by the sacred year long known to the priests

But if everything had gone on then as the priests of Tanis imagined, the Egyptian new year's day, *if* determined by the heliacal rising of Sirius, would not always afterwards have been the 1st of Payni, although the solstice and Nile flood would have been due at Memphis about the 1st of Pachons, and this is, perhaps, one among the reasons why the decree was to a large extent ignored

Hence, for some years after the date of the decree of Tanis there were at least three years in force the new fixed year, the new vague year, reckoning from Pachons, and the old vague year, reckoning from Thoth

But after some years another attempt was made to get rid of all this confusion The time was 23 B C, 216 years after the decree of Tanis, and the place was Alexandria Hence the new fixed year introduced is termed the Alexandrine year

This new attempt obviously implied that the first one had failed, and the fact that the vague year was continued in the interval is sufficiently demonstrated by the fact that the new year was $2\frac{1}{4}$ – 54 days *en retard* In the year of Tanis it is stated that the 1st Pachons, the new New Year's Day, the real beginning of the flood, fell on the 19th of June (Gregorian), the summer solstice, and hence the 1st of Thoth fell on the 22nd of October (Gregorian) In the Alexandrine year the 22nd of October is represented by the 29th of August, and the 19th of June by the 20th of April

It is noteworthy that in the Alexandrine year the heliacal rising of Sirius on the 23rd of July (Julian) falls on the 29th of Epiphi, nearly the same date as that to which I first drew attention in the inscriptions of the date of Thotmes and Pepi This, however, it is now clearly seen, is a pure accident, due to the break of continuity before the Tanis year, and the *slip* between that and the Alexandrine one It is important to mention this, because it has been thought that somehow the "Alexandrine year" was in use in Pepi's time !

It would seem that the Alexandrine revision was final, and that the year was truly fixed, and from that time to this it has remained so, and must in the future for ever remain so It must never be forgotten that we owe this perfection to the Egyptians

One of the chief uses of the Egyptian calendar that has come down to us was the arrangement and dating of the chief feasts throughout the year in the different temples

The fact that the two great complete feast calendars of Edfu and Esne refer to the only fixed years evidenced by records, those of Tanis and Alexandria, one of which was established over 200 years after the other, is of inestimable value for the investigation of the calendar and chronology of ancient Egypt

In an excellent work of Brugsch, "Three Festival Calendars from the Temple of Apollinopolis Magna (Edfu) in Upper Egypt," we have two calendars which we can refer to fixed years, and can date with the greatest accuracy In the case of one of these, that of Esne, this is universally recognized, as to the other, that of Apollinopolis Magna, we are indebted to the researches of Krall, who points out, however, that "it is only when the province of Egyptian mythology has been dealt with in all directions, that we can undertake a successful explanation of the festival catalogues Even externally they show the greatest eccentricities, which are not diminished but increased on a closer investigation"

[1] Goodwin has already asked, "Does the Smith Papyrus refer to some rectification of the Calendar made in the 4th Dynasty, similar to that made in Europe from the old to the new style," quoted by Riel, 'Sonnen und Sirius-Jahr," p. 361

About some points, however, there is no question The summer solstice is attached in the Edfu calendar to the 6th Pachons, according to Krall, while the beginning of the flood is noted on the 1st of that month In the Esne calendar, the 26th Payni is New Year's Day We read —"26th Payni, New Year's Day, Feast of the Revelation of Kahi in the Temple To dress the crocodiles, as in the month of Mechir, day 8"

Peculiar to the Esne calendar, according to Krall, is the mentioning of the "New Year's Festival of the Ancestors" on the 9th of Thoth, to the Edfu calendar, publication No 1 of Brugsch, the festival "of the offering of the first of the harvested fruits, after the precept of King Amenemha I.," on the 1st Epiphi, and "the celebration of the feast of the great conflagration" on the 9th of Mechir In feast calendar No 1, the reference to the peculiar Feast of Set, is also remarkable, this was celebrated twice, first in the first days of Thoth (? 9th ?), then, as it appears, in Pachons (10th) This feast is well known to have been first mentioned under the old Pharaoh Pepi Merinrā

It is a question whether in the new year of the ancestors and the feasts of Set, all occurring about the 9th Thoth and Pachons, we have not Memphis Festivals which gave way to Theban ones, for so far as I can make out the flood takes about nine days to pass from Thebes to Memphis, so that in Theban time the arrival of the flood at Memphis would occur on 9th or 10th Thoth There is no difficulty about the second dating in Pachons, for as we have seen this followed on the reconstruction of the calendar

It is also worthy of note that the feast of the "Great Conflagration" took place very near the Spring Equinox

It is well to dwell for a moment on the Edfu inscriptions to see if we can learn from them whether they bear out or not the views brought forward with regard to this reconstruction

As we have seen it is now acknowledged that the temple inscriptions at Edfu (which are stated to have been cut between 117 and 81 B C) are based upon the fixed year of Tanis, hence we should expect that the rising of Sirius would be referred to on 1 Payni, and this is so But here, as in the other temples, we get double dates referring to the old calendars, and we find the "wounding of Set" referred to on the 1st Epiphi and the rising of Sirius referred to under 1 Mesori Now this means, if the old vague year is referred to, as it most probably is, that

$$\begin{array}{l} 5 \text{ Epacts} \\ 30 \text{ Mesori} \\ \hline 35 \times 4 = 140 \text{ years} \end{array}$$

had elapsed since the beginning of a Sothic cycle, when the calendar coincidences were determined, which were afterwards inscribed on the temple walls We have, then, 140 years to subtract from the beginning of the cycle in 270 B C This gives us 130 B C, and it will be seen that this agrees as closely as can be expected with my view, whereas the inscription has no meaning at all if we take the date given by Censorinus

I quote from Krall[2] another inscription common to Edfu and Esne, which seems to have astronomical significance

"1 Phamenot Festival of the suspension of the sky by Ptah, by the side of the god Harschaf, the master of Heracleopolis Magna (A1) Festival of Ptah Feast of the suspension of the sky (Es)

"Under the 1st Phamenot, Plutarch, de Iside ac Osiride c. 43, b, notices the ἔμβασις Ὀσίριδος εἰς τὴν σελήνην These are festivals connected with the celebration of the winter solstice, and the filling of the Uza-eye on the 30th Mechir Perhaps the old year, which the Egyptians introduced into the Nile valley at the time of their immigration, and which had only 360 days, commenced with the winter solstice Thus we should have in the 'festival of the suspension of the sky,' by the ancient god Ptah—venerated as creator of the world—a remnant of the time when the winter solstice marked the beginning of the year, and also the creation"

The reconstruction of the calendar naturally enhanced the importance of the month Pachons, this comes out very clearly from the inscriptions translated by Brugsch On this point Krall remarks —

"It is therefore quite right that the month Pachons, *which took the place of the old Thoth by the decree of Tanis*, should play a prominent part in the feast calendars of the days of the Ptolemies, and the first period of the Empire in general, but especially in the *Edfu* calendar, which refers to the *Tanitic* year The first five days of Pachons are dedicated in our calendar to the celebration of the subjection of the enemies by Horus, we at once remember the above mentioned (p 7) record of Edfu of the nature of a mythological calendar, describing the advent of the Nile flood On the 6th of Pachons—remember the great importance of the sixes in the Ptolemaican records—the solstice is then celebrated The Uza-eye is then filled, a mythical act which we have in another place referred to the celebration of the solstice, and "everything is performed which is ordained" in the book "on the Divine Birth"

Next let us turn to Esne The inscriptions here are stated to be based on the Alexandrian year, but we not only find 1st Thoth given as New Year's Day, but 26 Payni given as the beginning of the Nile flood

Now I have already stated that the Alexandrine year was practically a fixing of the vague Tanis year; that is, a year beginning on 1st Pachons in 239 B C

If we assume the date of the calendar coincidences recorded at Esne to have been 15 B C (we know it was after 23 B C and at the end of the Roman dominion), we have as before, seeing that, if the vague Tanis year had really continued, it would have swept forward with regard to the Nile flood,

$$\begin{array}{l} \text{Pachons } 30 \\ \text{Payni } \ \ 26 \\ \hline 56 \times 4 = 224 \text{ years after } 239 \text{ B C} \end{array}$$

This double dating, then, proves the continuation of the vague year of Tanis if the date 15 B C of the inscription is about right

Can we go further and find a trace of the old cycle beginning 270 B C? In this case we should have the rising of Sirius

$$\begin{array}{r} 270 \\ -\ 15 \\ \hline 4)255 \text{ years} \\ \hline 64 = \text{say } 5 \text{ Epacts and } 2 \text{ months} \end{array}$$

This would give us 1 Epiphi Is this mentioned in the Esne calendar? Yes, it is, "1 Epiphi To perform the precepts of the book on the second divine birth of the child Kahi"

Now the 26th Payni, the new New's Year Day, is associated with the "revelation of Kahi," so it is not impossible that "the second divine birth" may have some dim reference to the feast

It is not necessary to pursue this intricate subject further in this place, so intricate is it that, although the suggestions I have ventured to make on astronomical grounds seem consistent with the available facts, they are suggestions only, and a long labour on the part of Egyptologists will be needed before we can be said to be on firm ground

J. NORMAN LOCKYER.

PROPOSED HANDBOOK TO THE BRITISH MARINE FAUNA

THE admirable monographs issued under the auspices of the Ray Society, and in Van Voorst's series, by such well-known authorities as Forbes and Hanley, Alder and Hancock, M'Intosh, Allman, Hincks, Brady, Norman, and others, are amongst the most creditable and useful productions of British Zoology, and all naturalists must devoutly trust that there are still others of a like classical nature to follow, and that, for example, Prof M'Intosh will soon be able to complete his long-expected work on the British Polychæta

But many Marine zoologists feel that, quite apart from such exhaustive and expensive monographs, and only aspiring to occupy a very much humbler position, there is pressing need of a "pocket" or seaside "Invertebrate Fauna," which could be used in much the same way as the botanists' "Field Flora" It has been suggested to me more than once during the last few years that I would be doing useful work in compiling such a book, and as no one else seems ready or willing to do so, I feel inclined to make the attempt Some material has already been accumulated for the purpose, but before going further I wish to lay my views before my fellow zoologists, in the hope that they will be kind enough to criticize the scheme and give me the benefit of their advice

The only existing work of the kind is Gosse's well-known, and, so far as it goes, very excellent little "Manual of Marine Zoology," but that book does not really meet the present want, as not only is the date of publication 1855-6, since when the number of genera and species has probably been something like doubled, but also Gosse merely gives the names of the species, while the book I think of would, in order to be of any real use, require to aim at giving a brief but sufficient diagnosis and figure of every British species I would adopt as "British" the area defined by Canon Norman's British Association Committee in 1887

Probably the most convenient form of publication would be some four to six small volumes, each dealing with one or two of the large groups This would allow of the groups being published as they were ready, not necessarily in zoological order, and would also be convenient for the use of those interested in one set of animals

There would be definitions—perhaps with occasional analytical tables or keys—of orders, families, &c, down to and including genera Under each genus would be given all sufficiently defined species with a brief description of each either in tabular form or in series, as seems most suitable in each case, and with an indication of size, range, and habitat Many species might be described very briefly in terms of preceding species, the differences merely being pointed out By simplicity of language, avoidance of unnecessary repetition, and use of contractions it might be hoped that each species could be confined on an average to a couple of lines

Illustrations would be either in the form of numerous small outline figures on thin paper plates inserted as near as possible to the pages where the descriptions occur, or as small groups of cuts (as in "Gosse") in the text There would be a figure of the whole animal in each important genus, or small family, and the figures of the species would represent the diagnostic points only, *e g* in the zoophytes there would be a figure in the genus *Plumularia* of an entire colony, or shoot, while the species *pinnata*, *setacea*, *catharina*, &c, would be represented each by a small figure showing the pinnæ, calycles, or nematophores as the case required

I shall now give a few examples, taken from different groups, of the method in which the genera and species might be treated, in order that specialists may have the opportunity of judging and criticizing

I From Cœlenterata —Genus ANTENNULARIA
Stems simple or branched, pinnæ verticillate, nematophores along the stems gonothecæ axillary, unilateral

A antennina, L, stems clustered, usually simple, hydrothecæ separated by 2 joints 6 to 9 in high Gen distr deep w

A ramosa, Lamk, stems single, usually branched, hydrothecæ separated by 1 joint only 6 to 9 in high Gen distr deep w

II From Crustacea —Family MAIIDÆ

HYAS Carapace tuberculous, no spines, branches of rostrum not divaricated, second joint of antenna dilated, no teeth beneath last joint of walking legs

H araneus, L, carapace not contracted behind post-orbital process 3 in Common, shallow

H coarctatus, Leach, carapace contracted behind post-orbital process 1 in Gen distr shallow

PISA Carapace may be tuberculous, with strong postero-lateral spine branches of rostrum divaricated at extremity, second joint of antenna slender, terminal joint of walking legs toothed beneath

P tetraodon, Leach, carapace with small tubercles, antero lateral margin with 4 spines 2 in Rare, S coast

P gibbsii, Leach, carapace with large rounded elevations, but no tubercles, no spines on antero lateral margin Rare, deep w, S coast

MAIA Carapace covered with numerous sharp spines, branches of rostrum strongly divaricated, no teeth beneath terminal joint of walking legs

M squinado, Latr 10 in long S and W coasts of England

III From Tunicata —Family MOLGULIDÆ

EUGYRA Branchial sac with no folds

E glutinans Möll, circular area on side free from sand ½ in Shallow w, gen distr

E globosa, Hanc, entirely covered with sand ½ in

PERA Branch s with 5 folds each side

P hancocki, Hrdn, matted fibres at poster end ½ in Irish Sea, 20 fms

MOLGULA Branch s with 6 or 7 folds each side

M inconspicua A & H, 6 folds, sandy, dors lam entire, no pap on stigmata ¼ in

M impura, Hel, 6 folds, sandy, small papillæ on edges of stigmata 1 in W of Ireland, shallow

M simplex, A & H, few hairs, little or no sand, 6 folds, anus fringed, dors tub horse shoe, aperture to left ½ ¾ in

M tubifera, Örst, 6 folds, anus fringed, dors tub horse-shoe, dors lam toothed, sandy 1 in E coast

M ampulloides, v Ben, 6 folds, anus fringed, dors tub horse shoe, 3 bars on fold, dors lam entire 1 in E coast, shallow

M socialis, Ald, 6 folds, anus fringed, dors tub horse-shoe, 4 bars on fold, dors lam entire, sandy, gregarious ½ in shallow w S coast

M holtiana, Hrdn, 6 folds, dors tub serpentif, hairs but little sand on test ¾ in W of Ireland, 10 fms

M occulta, Kupf, 7 folds, dors tub horse shoe, dors lam toothed, whole body sandy 1 in Shallow w S and W coasts

M oculata, Forb, 7 folds, siphonal region alone free from sand, and retractile between folds of test 1 in Gen distr Shallow w

M cephiformis, Hrdn, 7 folds, globular, not attached, no sand ¾ in S coast, shallow w

M citrina, A & H, 7 folds, attached by left side, no sand ¼–½ in under st, litt E and W coasts

CTENICELLA, as MOLGULA, but branchial and atrial lobes laciniated

C complanata, A & H, 6 folds on left, 7 on right, depressed attached, sandy, ¼ in

In conclusion, I need scarcely say that I shall be very grateful for suggestions, and, if the work is carried on, for any information from specialists about less known species, and the discrimination of allied forms, and for specimens, and also for references to any descriptions which might be likely to escape my notice

W A HERDMAN

NOTES

IN consequence of the unavoidable absence abroad of the new President of the Institution of Electrical Engineers, Mr W H Preece, F R S, on the 12th inst, he will deliver his inaugural address on the 26th inst.

A PUBLIC meeting, arranged by the Technical Instruction Committee of the Essex County Council, will be held in the Shire Hall, Chelmsford, on Friday afternoon, January 13, at 4.30 p m, Lord Rayleigh in the chair. An address will be given by Sir Henry E Roscoe on technical instruction in agricultural counties, with especial reference to science teaching Afterwards a discussion will take place

DR PERCY RENDALL, F Z S, has accepted an appointment as Resident Medical Officer to the Sheba Gold-mining Company in the Barberton District of the Transvaal He will reside at Eureka City, at an elevation of 5000 feet above the sea level Dr. Rendall made a good collection of birds during his recent residence at Bathurst on the Gambia, of which he has given an account in the *Ibis* for last year (*Ibis*, 1892, p 215) He has also made many valuable donations to the Zoological Society's Menagerie, amongst which is the unique example of the Nagor Antelope (*Cervicapra redunca*), presented by him in June, 1890 Of this scarce animal there is, we believe, no example in the British Museum Dr Rendall's new appointment will give him many opportunities of extending our zoological knowledge of a little known district

LORD WALSINGHAM, who has devoted much of his attention to the micro-lepidoptera, has filled the vacancy on the staff of the *Entomologists' Monthly Magazine* occasioned by the death of Mr Stainton

LAST week a preliminary meeting was held at the house of Sir James Paget to consider what steps should be taken with regard to a memorial of Sir Richard Owen It was decided that a committee should be formed to make the necessary preparations The following, among others, have consented to serve as members —The Presidents of the Royal Colleges of Physicians and Surgeons and of most of the scientific societies, the Duke of Teck, Lord Playfair, Prof Huxley, Sir Joseph Hooker, Sir Henry Acland, Sir John Evans, Dr Michael Foster, Mr Sclater, Sir W Savory, Mr. Hulke, Sir Joseph Fayrer, Sir Edward Fry, Dr Günther, Mr Carruthers and Dr H Woodward Sir William Flower will act as treasurer, and a general meeting will shortly be called. It has been suggested that the memorial should be a marble statue, to be placed in the hall of the Natural History Museum

PROF WESTWOOD, who died on Monday at the age of eighty-seven, will be greatly missed at Oxford To most people he is known chiefly as a writer on the archæology and palæography of art, but he was equally eminent as an entomologist He was one of the founders of the Entomological Society, and received one of the Royal Society's gold medals for his entomological researches.

WE regret to record the death of General Axel Wilhelmovitch Gadolin, an old member of the Russian Academy of Sciences. He was born of Finnish parents on July 10, 1828, received his education in the Finnish Corps of Cadets, and till his death remained in the Russian Artillery, devoting his leisure time to mineralogical, and especially to mathematical, researches into the molecular forces which act in the formation of crystals One of his earlier works, published in the *Verhandlungen der Mineralogischen Gesellschaft zu St. Petersburg*, was on some minerals from Pitkäranta. His chief work, published in 1867, was his "Deduction of all the Systems of Crystals and their Derivates from a Unique Principle" A deep impression was produced upon the members of the Russian Mineralogical Society by Gadolin's first communication upon this subject. The lucidity with which he deduced all systems of crystallization from fundamental principles of equilibrium of molecular forces, and the simplicity of the exposition of his researches, entirely based upon high mathematical analysis, reminded his hearers of some of the best pages of Laplace's writings The work soon became widely known in a German translation A paper on the resistance of the walls of a gun to the pressure of gunpowder gases also deserves mention, as, in addition to the formerly known formulæ of highest resistance of cylinders, he gave a new formula of minimal resistance Later on his method was used with great success by Klebsch, in his well-known "Theorie der Elasticität fester Körper," for deducing some general equations of equilibrium of solid bodies

THE last issue of the *Izvestia* of the East Siberian Geographical Society (vol xxiii 3) contains an obituary notice by V Obrutcheff, of I D Chersky, who died in the far north east of Siberia, during his expedition to the Kolyma river, after having given many years of his life to the active geological exploration of Siberia He began his work in 1872 at Omsk, where he made most valuable discoveries of post-tertiary mammals During the next two years he explored the Tunka and Kitoi Alps, but his rich materials were lost during the great conflagration at Irkutsk in 1879 In 1875 and 1876 he explored the Nijneudinsk caves, making again remarkable finds of quaternary mammals, and then he gave fully five years to the study of the stores of Lake Baikal, embodying the results of his extensive researches in a map (6 7 miles to the inch), and in vol xii of the *Memoirs* of the East Siberian Society, and vol xv of the *Memoirs* of the Russian Geographical Society In 1882 and 1883 he explored the Lower Tunguska, and again made rich finds of fossil mammals The next five years he spent at the Academy of St Petersburg, preparing the part of Ritter's "Asia" which is devoted to Lake Baikal, and working out the rich materials collected by another lamented Polish explorer of East Siberia, Czekanowski He also worked out the collections brought in from the New Siberia Islands by MM Bunge and Toll, and came to such interesting and new conclusions as to the recent geological history of Arctic Siberia, that the Academy of Sciences sent him out in 1891, at the head of a new expedition to the Kolyma region There he died, in the midst of his promising work

THE twentieth annual dinner of the old students of the Royal School of Mines will be held at the Holborn Restaurant, on Tuesday, January 10, at 7 o'clock The chair will be taken by Mr W Gowland, late of the Imperial Mint, Osaka, Japan

MR G T ATKINSON has been appointed Professor of Cryptogamic Botany at Cornell University, Ithaca, State of New York, in the place of Prof W R Dudley, who has gone to the Leland Stanford University, Paolo Alto, California.

AT the next public meeting of the French Academy, in December 1893, forty-five prizes will be awarded for the best work tending to the advancement of the various branches of science Of these, the following are, by the terms of the bequests, open to competitors of all nationalities The Prix Lalande will be awarded for the most intereresting observation, or the memoir or work most useful for the progress of Astronomy Its value is 540 francs The Prix Valz, of 460 francs, is offered under the same conditions. Three prizes of 10,000 francs each, bequeathed by M. L. La Caze, will be awarded annually for the best contributions to Physiology, Physics, and Chemistry respectively The Prix Tchihatchef, of 3000 francs, is offered annually to naturalists who have distinguished themselves most in the exploration of the continent of Asia or the adjacent Isles.

excluding better known regions such as British India, Siberia proper, Asia Minor, and Syria. The explorations must have some object connected with Natural Science, physical or mathematical, and will not be awarded for archæological or ethnographic work. All these prizes will be awarded in December 1893. Works for competition to be sent in to the *Sécrétariat* before June 1. The Prix Leconte, of 50,000 francs, for the most important scientific discovery, will be awarded in 1895.

THE Royal Academy of Sciences of Turin, in accordance with the will of Dr. Cesare Alessandro Bressa, and in conformity with the programme published December 7, 1876, announces that the term for competition for scientific works and discoveries in the years 1889–92, to which only Italian authors and inventors were entitled, was closed on December 31, 1892. The ninth Bressa prize will be given to the scientific author or inventor, whatever be his nationality, who during the years 1891–94, "according to the judgment of the Royal Academy of Sciences of Turin, shall have made the most important and useful discovery, or published the most valuable work on physical and experimental science, natural history, mathematics, chemistry, physiology and pathology, as well as geology, history, geography and statistics." The term will be closed at the end of December 1894. The sum fixed for the prize, income tax being deducted, is 10,416 francs. Any one who proposes to compete must declare his intention within the time above mentioned, by means of a letter addressed to the President of the Academy, and send the work he wishes to be considered. The work must be printed. Works which do not obtain the prize will be returned to the authors, when asked for within six months from the adjudication of the prize. None of the national members, resident or not resident, of the Turin Academy can obtain the prize. The Academy gives the prize to the scientific man considered most worthy of it, even if he has not competed.

MESSRS. MACMILLAN AND CO. hope to publish early in the spring the second volume of Dr. Arthur Gamgee's Treatise on Physiological Chemistry. This volume, which deals with the Digestive Processes, will be followed at no long interval by an enlarged and revised edition of the first volume, which originally appeared in 1880.

THE United States Government is inviting the various European Governments to send delegates to an International Conference of Meteorologists, to be held at Washington. The following is said to be proposed as a provisional programme of topics to be discussed by the Conference:—(*a*) The organization of additional meteorological work for the benefit of agriculture. (*b*) The extension to all ports frequented by commerce of the benefits of systematic storm and weather signals, and the introduction of a uniform system of storm warnings throughout the world. (*c*) The co-operation of all nations in the publication of a daily chart of the weather over all the habited lands and frequented oceans for the study of the atmosphere as a whole, and as preparatory to the eventual possibility of predicting important changes several days in advance. (*d*) The equable apportionment of stations, publications, and expenses among the nations, and the suggestion of practical methods by which to secure observations from those countries that are not represented in this Conference. (*e*) The encouragement by the respective Governments of special scientific investigations looking to the advancement of meteorology. Such other matters as the delegates may think advisable to submit for discussion, or for future report, will also be considered.

DURING the past week the sharp frost has continued almost uninterruptedly over these islands, with the exception of a partial thaw on Friday and Saturday, caused by a disturbance in the west spreading to the eastward. The greatest increase of temperature occurred in the north and west, but in the south-east of England the day readings were only slightly above the freezing-point. There was a complete change in the type of weather at the close of the week; a large anticyclone had formed over Scandinavia, and the air over nearly the whole of Europe was intensely cold, the minimum in the shade at Haparanda on Sunday registering 72° below the freezing-point, and the barometer on subsequent days rose to 31 inches and upwards in these islands. These conditions were accompanied by cold easterly gales in the south west of England, while a heavy fall of snow was experienced in the south-eastern districts. On the coast of Kent the shade minimum fell to 11° during Monday night. The *Weekly Weather Report* issued on December 31 shows that the temperature of that period was much below the mean, amounting to 9° or 10° over the greater part of England, and to 12° in the Midland counties. Very little rain fell during the week; the deficiency of rainfall in the south-western district of England for the last year amounts to 10·8 inches, or more than 25 per cent. below the average of the 25 years 1866–90. A good deal of fog was experienced at the inland stations during the week.

SOME very interesting entomological notes from the Eastern Archipelago are given by Mr. J. J. Walker in the January number of the *Entomologists' Monthly Magazine*. Incidentally Mr. Walker mentions that Dr. Wallace's residence in these islands, after a lapse of more than thirty years, is not forgotten, and that the Dutch translation of the "Malay Archipelago" is "as highly appreciated in the lands of which he gives so vivid a picture as the original work is at home."

AT the Physikalisch-Technische Reichsanstalt, Berlin, copies of standard mercury resistances are being constructed in which the mercury does not require renewal (*Wiedemann's Annalen*). They consist of U-shaped tubes filled with mercury in a vacuum and then sealed by fusion. Into each of the ends are fused three thin platinum wires connecting with the main current, the secondary circuit, and the galvanometer respectively. Since the connections are rigidly joined to the glass, it is possible to employ platinum wires as thin as 0·3 mm., so that there is no danger of heat being conducted into the mercury from without. The copy, mounted in a perforated brass box with an ebonite lid, is immersed in petroleum contained in another brass box, so that the binding screws are covered. This box is again surrounded during the experiment with a mixture of fine ice and water. The resistance is thus taken at a temperature which can easily be obtained, and which is uniform throughout the containing vessel.

AN apparatus for demonstrating the difference of potential at the poles of a galvanic cell has been constructed by Messrs. Elster and Geitel, of Wolfenbuttel (*Zeitschr. fur Phys. und Chem. Unterricht*). It is a modification of Thomson's water dropping influence machine. Two insulated metallic vessels can be filled with water by pressing a rubber ball communicating with a three-necked jar. The jets enter the vessels through two metal rings. One of these rings is connected with the positive pole of the cell. The jet on passing through becomes negatively charged, and the charge is communicated to the vessel and through a wire to the second ring, which acts by induction on the other jet. A strong positive charge is soon accumulated on the outside of the second vessel, and can be exhibited by a gold leaf or aluminium foil electroscope.

IN 1869 it was decided, in France, to give a medal and pension of 250 francs to every old soldier of the Republic and the Empire who could show two years of service, or two campaigns, or a wound. An interesting statistical record of these "médaillés de Sainte Hélène" as of "a generation which is disappearing," is given by M. Turquan in the *Revue Scientifique*. The first list, in 1870, comprised 43,592 names; and these men

must have almost exclusively served under the Empire. They are now reduced to 27. The oldest, Vivien by name, a Lyons man, is now 106. When 13 he was with Bonaparte in Egypt, fought in 22 campaigns, and was one of the Imperial Guard at Waterloo. The youngest is 92, and served in the navy. The mean age of the 27 survivors is 97 or 98 years. The annual number of deaths in this body of men reached a maximum of 6456 in 1872, since which year it has been gradually diminishing. The proportional mortality rose, in general, till 1889, but in the years since there has been a marked fall, testifying to the exceptional vitality of those late survivors. M. Turquan calculates that this remnant will have wholly disappeared by the end of the century. Going back to 1815, he estimates the generation to which the men belong at about 300,000, with a mean age of 25 years, and that 500,000 births between 1785 and 1795 would concur to its formation. From figures relating to the Napoleonic wars he comes to the grim conclusion that one man in five of those born between the years just named was destined to die in war. It is, he says, to the immense losses of men during the ten years of war of the Empire that the present generations owe their low birth rate.

MR. J. R. S. CLIFFORD offers some interesting observations in the January number of *Nature Notes*—the Selborne Society's magazine—on the Death's head moth and bees. Last July a friend of his at Gravesend found one of these huge moths trying to gain access to a hive, having evidently been drawn to the spot by the odour of the honey. This disposes of doubts which have been suggested as to the old statements about this moth's habit of entering hives when it has a chance. The construction of modern hives keeps it out, but "where old style hives are used, the moth can and does enter, and occasionally one has been found dead within a hive, the bees, being unable to remove so bulky an insect, having taken the precaution to embalm its body with what is called *propolis*." According to Mr. Clifford, some Continental bee keepers have discovered that "the bees are aware they are liable to the intrusions of this big moth," and when the bees are "located in the old fashioned hive, the insects erect a kind of fortification at the portal. This is constructed with a narrow passage and a bend, past which the Death's head could not possibly make its way, and which it has no jaws to bite through."

WE learn from the *Agricultural Journal*, issued by the Department of Agriculture at Cape Colony, that much attention is being given there to questions connected with the fruit export trade. The department is in correspondence with the steamship companies with a view to securing every possible encouragement to the trade, which is expected to be taken up on a considerable scale this year. Replying to inquiries on the subject, the Castle Mail Packets Company announce that they will give every publicity to the rates of freight to be charged and the stowage arrangements, &c. The Company will also concede a somewhat lower rate for the less remunerative fruits carried in the cool chambers, and will reserve a cool and well ventilated part of the vessel for conveyance of fruit as ordinary cargo. Careful instructions have been issued to captains of the Company's vessels in regard to the stowage and carriage of fruit.

DR. THEODORE MAXWELL has issued a useful catalogue of Russian medical dissertations and other works he has collected and presented to the Royal College of Surgeons of England. In order that the dissertations may be of service to students who do not read Russian, he has indicated the nature of each work in English, and has given references to such abstracts in the *Lancet* or elsewhere as he has himself made or happens to be acquainted with.

AN excellent "Child Life Almanack" for 1893, by A. M. Clive Bayley, has been published by Messrs. G. Philip and Son. It is issued as an extra number of "Child Life," and the object, as the author explains, is to provide teachers with suggestions both for lessons to be prepared and observations to be made. Teachers who may wish to give "seasonable" lessons will find many most useful hints as to what really goes on in nature during the various periods of the year.

MR. JOHN BROWNING, optical and physical instrument maker, has issued an illustrated catalogue of magic, dissolving view, and optical lanterns, lime light apparatus, and slides.

THE extraordinary diversity in the temperature at which different micro organisms flourish and multiply, has from time to time been the subject of some interesting investigations by Fischer, Globig, and others. Thus Fischer isolated fourteen different species of bacteria from the sea water in Kiel harbour, and from soil in the town itself. These he was actually able to cultivate successfully at the freezing temperature (0° C.) as well as at from 15° to 20° C. Globig, on the other hand, studied the behaviour of micro organisms at high temperatures and separated out no less than thirty varieties from garden soil which would grow at 60° C. Some of these were even able to develop at 70° C., whilst the majority refused to grow at all below 50° C., some still more fastidious individuals objected to any temperature below 60° C., and others again required a temperature of between 54° and 68° C. One bacillus, however, was discovered more catholic in its taste in this respect, for whilst growing at 68° C. it managed to develop also at from 15° to 20° C. Some fresh contributions on the growth of micro organisms at low temperatures have recently been made by Forster of Amsterdam ("*Ueber die Entwickelung von Bakterien bei niederen Temperaturen*"). As far back as 1887 Forster described a phosphorescent bacillus obtained from sea-water which was found not only capable of growing, but of producing the phenomenon of phosphorescence at 0° C. In further researches made by this investigator in conjunction with Bleekrode, it is stated that, although not many different species were found by them to develop at 0° C., yet immense numbers of individual bacteria belonging to this category were detected in very various media. Thus one cubic centimetre of milk as sent into the market contained 1000 such micro-organisms, whilst in a single gram of garden soil as many as 140,000 were found. Large numbers of such bacteria were also present in sea water obtained from the North Sea, and they were also found on the surface of fresh water fish as well as in their alimentary tract. It is well known that to successfully preserve meat and other articles of food it is necessary to employ a much lower temperature than 0° C., and experience has further shown that this is best done when the atmosphere is deprived of all moisture, as is accomplished by the compression and subsequent expansion of the air in enclosed spaces. Haddocks imported from Norway and thus artificially frozen were examined by Forster for bacteria. These fish were first killed and then exposed to a temperature of from 20° to 40° below 0° C. until they became perfectly hard and stiffly frozen, when they were removed to a cold chamber in which the temperature varied from 8° to 15° below 0° C. In spite of the extremely low temperature to which these fish had been subjected, on examining them when still hard frozen, a considerable number of bacteria were found in the abdominal cavity which had been opened when the fish was killed. It is obvious that during the interval which elapsed between the killing of the fish and their transference to the freezing chamber, bacteria must have been able to gain access, but had not had time to multiply to any considerable extent before the fish was frozen. Forster points out, what is sufficiently apparent, that the packing of samples of water in ice when sent from a distance

for bacteriological examination to prevent the multiplication of the micro organisms present, is really of very little if any use at all Thus it was already shown several years ago by Percy Frankland that the bacteria in filtered Thames water were able to multiply extensively, even when preserved for some days in a refrigerator

THE additions to the Zoological Society's Gardens during the past week include a Bittern (*Botaurus stellaris*), European, presented by Lord Ilchester, F Z S , two Hamsters (*Cricetus frumentarius*), British, presented by Miss Pugh , two Alligators (*Alligators mississippiensis*), from Florida, presented by Master Williams , a Common Snipe (*Gallinago cœlestis*), British, purchased

OUR ASTRONOMICAL COLUMN

COMET HOLMES (NOVEMBER 6, 1892) —The following is a continuation of Herr Berberich's ephemeris of this comet, the places being for Berlin, midnight —

		R A (h m s)	Decl (° ′)	Log r	Log Δ
Jan	5	1 8 50	33 47 9	0 4119	0 3400
	6	9 59	46 4		
	7	11 8	45 0		
	8	12 18	43 7		
	9	13 30	42 6	0 4143	0 3516

The comet is now near to and south following β Andromedæ Reports from various Observatories state that the comet is now very dim

COMET BROOKS (NOVEMBER 20, 1892) —This comet is now travelling very quickly The ephemeris for Berlin, midnight, is continued below —

		R A (h m s)	Decl (° ′)	Log r	Log Δ	Br
Jan]	5	18 29 40	+66 5 4	0 0805	9 8562	7 82
	6	19 0 49	13 6			
	7	19 31 22	65 59 2			
	8	20 0 22	24 6	0 0806	9 8651	7 49
	9	20 27 8	64 32 4			
	10	20 51 19	+63 26 0	0 0811	9 8781	7 01

The unit of brightness is taken as that at midnight on November 21

The track of the comet lies near the pole of the ecliptic, in the constellation Draco

THE SPECTRUM OF COMET HOLMES —The spectrum of the comet appears to have been continuous without any trace of bright bands At South Kensington it appeared to have its brightest part near the chief carbon fluting (λ 517), but there was nothing which could be described as a line or fluting As might be expected, there was a brighter continuous spectrum from the nucleus The same result was obtained by Mr Campbell at the Lick Observatory, and by Prof Keeler at the Allegheny Observatory The latter observer remarks that the spectrum is just what we should expect if the comet shines entirely by reflected sunlight

THE RECENT OPPOSITION OF MARS —In the December number of *Astronomy and Astro Physics*, Prof W H Pickering summarizes the conclusions derived from the observations of Mars at Arequipa as follows (1) That the polar caps are clearly distinct in appearance from the cloud formations, and are not to be confounded with them (2) That clouds undoubtedly exist upon the planet, differing, however, in some respects from those upon the earth, chiefly as regards their density and whiteness (3) There are two permanently dark regions upon the planet, which under favourable circumstances appear blue, and are presumably due to water (4) Certain other portions of the surface of the planet are undoubtedly subject to gradual changes of colour, not to be explained by clouds (5) Excepting the two very dark regions referred to above, all of the shaded regions upon the planet have at times a greenish tint At other times they appear absolutely colourless Clearly marked green regions are sometimes seen near the poles (6) Numerous so-called canals exist upon the planet, substantially as drawn by Prof Schiaparelli Some of them are only a few miles in breadth No striking instances of duplication have been seen at this opposition. (7) Through the shaded regions run certain curved branching dark lines They are too wide for rivers, but may indicate their courses (8) Scattered over the surface of the planet, chiefly on the side opposite to the two seas, we have found a large number of minute black points They occur almost without exception at the junctions of the canals with one another and with the shaded portions of the planet They range from thirty to one hundred miles in diameter, and in some cases are smaller than the canals in which they are situated Over forty of them have been discovered, and for convenience we have termed them lakes

The heights of some of the clouds were found to be not less than twenty miles, and indirect observations have led to the conclusion that the density of the atmosphere of the planet is less than that at the surface of the earth, but probably not as much as ten times less

Prof Pickering is of opinion that the opposition of 1894 will be quite as valuable to observers as that of 1892, the distance being but little greater, while the planet will be much farther north, and there is less likelihood of the surface being so much obscured by clouds as during the recent opposition

GEOGRAPHICAL NOTES

AN interesting illustration of the rapid development of South Africa is given by the recent appointment of a magistrate to reside near Lake Ngami to protect the interests of white traders, and enforce the laws restricting the sale of liquor and ammunition to the natives

THE January number of the *Geographical Journal*, the new form of the Proceedings of the Royal Geographical Society, contains a paper and map of some importance by Mr A P Harper, descriptive of the central part of the Southern Alps of New Zealand Government surveyors have been sent for several seasons to map out the glaciers, and an effort is being made by thoroughly exploring and mapping the region to make it the Switzerland of the southern hemisphere in the estimation of tourists, as it is already by virtue of its fine mountain systems

AN important paper on the physical conditions of the waters of the English Channel is published by Mr H N Dickson in the new number of the *Scottish Geographical Magazine* He shows how the ebb and flow of the tides in the Channel is affected by the characteristic form of the main feature of the coast line, viz bays with the western side running nearly from south to north, turning at a sharp angle, and lying open to the east The circulation of the water and its temperature were found to be largely determined by these conditions

MR COLES gave a successful lecture to young people in the hall of the University of London, on Friday last, covering the first half of his subject, "All the World Over," in a very interesting way Anecdotes of personal adventure combined with exceptionally fine limelight views of scenery to give a vivid impression of the regions touched upon The second and last juvenile lecture, under the authority of the Royal Geographical Society, will be given on Friday, January 6, at 4 p m

THE Royal Scottish Geographical Society announces a course of educational lectures in continuation of those delivered by Prof J Geikie and Dr H R Mill last year The new course will be on the Geographical Distribution of Animals, by Mr J Arthur Thomson, who is at present delivering the Thomson Lectures at Aberdeen The Society has also provided two special lectures to young people, by Prof C G Knott, on Life in Japan, and by Mr Graham Kerr on his recent travels in South America

WE understand that a book of travel in Madagascar and Africa, by Mrs Colvile, F R G S , describing the observations of the authoress on a recent extensive tour, will shortly be published by Messrs Blackwood

MR. J W. GREGORY, assistant in the Geological Department of the British Museum, has joined as naturalist the sporting expedition of Lieutenant Villiers and others, which is on the point of starting up the Juba From Bardera, the head of navigation, the party will traverse unknown regions to Lake Rudolf, and from there attempt to cross in a north-easterly direction, through the Galla country and Somaliland to Berbera on the Gulf of Aden

THE INTERNATIONAL ZOOLOGICAL CONGRESS AT MOSCOW

THE International Zoological Congress held its second session in Moscow during the month of August last, and with most commendable zeal the committee, to whose care the editing and publishing of the memoirs read were committed, now publish the first part of the volume of its Proceedings This part is printed in royal octavo size, and contains 350 pages, with several illustrations. All the memoirs are in French, thirteen out of the total thirty having been translated from, it is presumed, Russian In the first section—that of questions concerning biology and systematic and faunistic zoology from a general standpoint—there are three papers J de Kennel replies to the queries of Prof L Cosmovici (1) On a definite arrangement of the animal kingdom in "Phyla", (2) is there a type "Vermes"? (3) on a uniform terminology of the secretory organs of worms Ch Girard on some points of nomenclature J de Bédriaga on introduced species, and on hybrids, reptilian and amphibian In Section II—the same subjects from a special standpoint—there are twelve papers —P N Boutchinsky, on the Black Sea fauna, refers to a report on invertebrates of the Bay of Sebastopol by Péréiaslavtzeva, who records 639 forms found He describes three zones (1) from the surface to a depth of 175 feet, (2) from 175 to 280 feet in depth, with a minimum temperature of 6–7° C, and (3) from 280 to 700 feet, with a slightly higher temperature than in the previous zone, 8–9° C From a depth of 700 feet the water contains a quantity, more or less large, of sulphureted hydrogen, the quantity notably increasing with the depth T J Van-Beneden gives a note on the living and extinct Cetacea of the same sea. Gr Kojevnikov gives an account of the fauna of the eastern Baltic based on many recent explorations Dr J de Bedriaga treats of European and circum mediterranean vipers C Grévé has a paper on the geographical distribution of the Carnivores, and T Richard, one on the geographical distribution of the Cladocerous crustacea H de Jhéring makes some observations on insects' nests made of clay Prof A Brandt gives a classification of animal variations according to their causation Prof A Milne Edwards and E L Bouvier give a most interesting account of the varieties and distribution of *Parapagurus pilosimanus*, S I Smith A table with the comparative measurements of forty two specimens, is appended *P abyssorum* and var *scaber*, are reduced to the first named species F Vejdovsky describes *Thuricola gruberi*, n sp, and *Monodontophrya longissime*, gen et sp nov, the former from a stream near Bodenbach, the latter in the alimentary tract and body cavity of *Rhynchelmis limosella*, Holm In a short note Dr J de Bédriaga calls attention to some differences between *Chalcidis simonyi*, Steind, and *C viridanus*, which forms Boulenger and Steindacher have proposed to unite, and thinks that *Molge luschani*, Steind, neither belongs to Molge nor to Salamander, but to a European and American genus, not however named by him

The third section contains eight papers on histology and embryology N Kholodovski, contributions to a mesoderm and metamere theory A Pitzine, note on the formation of the germ of the peripheric nervous system V Roudnev, note on the development of the cardiac endothelium in Amphibians Mme O Tikhomirova, on the development of *Chrysopa perla* Fr Vejdovsky, on the segmentation of the ovum and the formation of the blastoderm in the Pseudoscorpiones, and on a rudimentary organ in the same N Koulaguine, contribution towards the history of the parasitic hymenoptera. A Tikhomirov, value of embryological research for classification. Section IV, physiology —C Khvorostansky, on the luminosity of animals from the White Sea

H de Jhéring, on the presence or absence of an excretory apparatus in the genital organs of the metazoa P Mitrophanov, note on the metameric significance of the cranial nerves N Nassonov, on the position of the Strepsiptera in the animal system, according to the facts of post embryonal development and of anatomy A O. Kovalevsky, on the excretory organs of the terrestrial Arthropods N. Zograf, on the origin and parentage of the Arthropods, more especially the tracheal bearing forms.

A BOTANIST'S VACATION IN THE HAWAIIAN ISLANDS

THE new number of the American *Botanical Gazette* (vol xvii, No 12) contains the first part of a paper by Prof D H Campbell, describing his experiences during a vacation spent last summer in the Hawaiian Islands We reprint the following passage —

On awakening upon the seventh day out, and looking through the port hole of my state-room, I saw that we were sailing near land Rugged barren looking hills were seen, and, going upon deck, I learned that this was Oahu, the island upon which Honolulu is situated As we skirted the shore at a distance, I soon spied a grove of unmistakable cocoa palms, the first hint of the tropical vegetation to which I was soon to be introduced Beyond was the bold promontory of Di mond Head, an extinct volcanic crater, forming a great bowl with rugged sides, right at the water's edge Beyond this, and bounded partly by it, is the bay upon whose shores stands the city Back of it rose abruptly a chain of mountains, in places about three thousand feet above sea level, and furrowed by deep valleys, whose walls, as well as the cloud capped summits of the hills, were covered with the most wonderfully verdant vegetation Never before had I realized the possibilities of green Blue greens, yellow greens, gray greens, and positive greens, with all degrees of these and others that are indescribable, combined to form what Whistler would term a symphony in green

As if to vie with the colours of the mountains, the sea exhibited an equally wonderful variety of tints. Outside the harbour is a coral reef, and within this the water is of the pale green common to shallow ocean water, but outside it deepens very rapidly into the vivid blue of the open ocean From a distance the line is clearly seen, but, as the observer approaches shore, the water changes from deep blue through every shade of blue and green until the pale green of the water within the harbour is reached

As we approached land numbers of the queer outrigger canoes of the natives were met, and from the wharf boys jumped into the water and swam about the ship in the hope of persuading some of the passengers to throw over to them coins, which they were very skilful in diving for

On the way to the hotel a few gardens were passed, and in them everything was strange By far the most striking thing was the superb *Poinciana regia* Although I had never seen this before I recognized it in an instant from a description of Charles Kingsley's, read long ago Surely in the whole vegetable kingdom there is no more splendid plant A spreading flat topped tree, perhaps thirty feet high, with feathery green, acacia like foliage and immense flat clusters of big flaming scarlet flowers that almost completely hide the leaves so that the tree looks like an immense bouquet They were in their prime about the time of my arrival in Honolulu, and continued to flower more or less for the next six weeks Pretty much everything in Honolulu, except the cocoanuts and an occasional haw tree (*Paritium tiliaceum*) is planted, but people seem to vie with each other in seeing how many different kinds of plants they can grow, and the result is that the place is like one great botanical garden. To Dr Hillebrand this is said to be largely due, as he was one of the first to introduce foreign ornamental plants, and his place, which is kept much as it was at the time he left the islands, was a very remarkable collection of useful and ornamental plants from the warm regions of almost the whole globe

Probably the first thing that strikes the traveller from the cooler regions is the great variety and number of palms Of these the beautiful royal palm (*Oreodoxa regia*) is easily first With its smooth columnar trunk, looking as if it had been turned, encircled with regular ring-shaped leaf-scars, and its crown of plumy green leaves, it well deserves its name. Other characteristic palms are various species of betel palms (Areca), wine palm (Caryota), sugar palm (Arenga), and a great variety of fan-palms of different genera. None is more beautiful than a thrifty young cocoa palm, but unfortunately it is very subject in the Hawaiian Islands to the ravages of some insect which eats the leaves and often renders them brown and unsightly Indeed, it is almost impossible to find a specimen which is not more or less disfigured by this pest. The trunk of the cocoanut tree is usually more or less crooked, and in old specimens much too tall

for its thickness, so that the old trees look top heavy. The date palm flourishes in Honolulu, where it is quite dry, but does not do so well in the wetter parts of the islands.

On studying the other trees, one is struck at once by the great preponderance of Leguminosæ, especially Cæsalpineæ and Mimoseæ. All about the town, and growing very rapidly, is the algaroba (*Prosopis juliflora*), a very graceful tree of rapid growth, with fine bipinnate leaves and sweetish yellow pods, which animals are very fond of, and which are used extensively for fodder. Add to this that the tree now forms the principal supply of fuel for Honolulu and we can realize its full value. Other leguminous trees that are planted are the monkey pod (*Pithecolobium samang*), tamarind, various species of Bauhinia and Cathartocarpus. One species of the latter with great drooping bunches of golden yellow flowers and enormous cylindrical pods three or four feet long, rivals the Poinciana when in full flower.

Mingled with these are a great number of shrubs and trees with showy flowers or leaves, most of them more or less familiar to the stranger, either from pictures or from green-house specimens. Several species of Musa are grown, and when sheltered from the wind are most beautiful; but ordinarily the leaves are torn into rags by the wind. The tall and graceful *M. sapientium* has been largely supplanted by the much less beatiful Chinese banana, *M. Cavendishii*, which is short and stumpy in growth, but enormously prolific. The related traveller's tree (*Ravenala Madagascariensis*), is a common and striking feature of many Hawaiian gardens. Of the many showy flowering shrubs, the beautiful *Hibiscus Rosa-Sinensis* is one of the commonest, and is used extensively for hedges. One of the most striking hedges in the city, however, is the famous one at Puna Hou college, which is 500 feet long and composed of night-blooming cereus. I was not fortunate enough to see this when it was in full flower, but I saw a photograph of it when it was estimated that there were about 8000 flowers at one time.

Of the fruit trees ordinarily grown, the following may be mentioned. The mango is a very handsome tree with dense dark green foliage and masses of yellow and reddish fruit on long hanging stalks. The bread fruit tree is common, both cultivated and wild, and is a very beautiful tree of moderate size, with leaves looking like immense fig-leaves, and the fruit like a large osage orange. I saw no ripe fruit, and so had not an opportunity of testing its quality. Guavas of different varieties are extremely common, both wild and cultivated, and the various fruits of the whole citrus tribe grow well. The few specimens of temperate fruits were, for the most part, much inferior to those of the United States. Of the fruits that did not strike my fancy, at least at first, was the alligator pear (*Persea gratissima*), a big green or purple pear-shaped fruit with an immense single seed. The pulp is somewhat waxy in consistence and very oily. It is eaten as a salad, and very much relished by the islanders, but the taste is acquired. The curious papaya (*Carica papaya*) is another fruit which did not appeal to my palate. Its big orange fruit, not unlike a melon in appearance when cut open, has a peculiar "squashy" flavour that suggested it having been kept a day too long.

Many showy climbers are planted, some of which, like Stephanotis, Thunbergia and Allamanda are superb; but there is one that is particularly obnoxious in colour, Bougainvillea, whose magenta floral bracts are an offence to the eye, forming a cataract of raw colour. It looks, as some one observed, as if it had just come from a chemical bath.

As soon as one gets fairly away from the city, it is at once seen that all the luxuriant vegetation is strange. Along the seashore is a plain gradually rising into low hills, both almost destitute of trees, except here and there a few cocoa palms along the shore. Of the strictly littoral plants among the most conspicuous is the curious *Ipomœa pes capræ*, with deeply two cleft leaves and purplish pink flowers. In the fertile lowlands near the sea are the principal cane and rice fields, which with taro are the staple crops. The rice is cultivated entirely by Chinese, near Honolulu; but on the sugar plantations the Japanese are largely employed. To see a Chinese laboriously transplanting little handfuls of rice into straight rows or ploughing in the mud and water with a primitive plough drawn by a queer Chinese buffalo are sights very foreign to an American eye. Sugar cane is eminently productive in the islands, and, hitherto, has proved the main source of revenue; but now the Hawaiians are bewailing the depression caused by the free admission of sugar from other countries into the United States; as, hitherto, their product has enjoyed practically a monopoly of the American market, having been admitted by treaty free of duty.

I made several trips up the valleys back of the city, but owing to the almost constant rain in many of them, these were not always agreeable. However, one is richly repaid by the luxuriance and variety of the vegetation. For a mile or two we pass between grass-covered hills, or hills overgrown in places with the lantana, which, introduced as an ornamental plant, has become a great pest. This plant covers some of the hills with an absolutely impassable thicket, and spreads very rapidly, so that it is a serious problem what is to be done with it. Of the common roadside plants, an orange and yellow milkweed and the showy white *Argemone Mexicana* were the most conspicuous. As one proceeds farther, where more moisture prevails, the variety becomes larger. Thickets of Canna and a Clerodendron with double rosy-white flowers, are common, and the curious screw-pine (*Pandanus odoratissimus*) is occasionally seen. This latter is a very characteristic plant, but is much more abundant in some of the other islands. In this region some very showy species of Ipomœa are very common, among them the well known moon-flower, *I. bona nox*.

With the increase in moisture, as might be expected, the mosses and ferns increase in number and beauty. There are many of them of types quite different from those of the United States. One of the commonest ferns of the lower elevation in *Microlepia tenuifolia*, a very graceful fern with finely divided leaves and terminal sori. Species of Vittaria, with very long undivided leaves, are also common here.

As we ascend one of the commonest ferns is *Sadleria cyatheoides*, a very large fern, often more or less arborescent. Ascending still higher the number and variety of ferns increases rapidly, and many beautiful and interesting ferns and mosses and liverworts become common.

At about one thousand feet elevation we begin to meet with species of Cibotium, to which genus belong the largest of the tree ferns of the islands. Here, also, I met for the first time with the smallest of all the ferns I have ever seen, *Trichomanes pusillum*. This dainty little fern, one of the Hymenophyllaceæ, forms dense mats on rocks and tree-trunks, looking like a delicate moss. The full grown frond is fan shaped, and, with its stalk, is not more than half an inch high. These tiny leaves, nevertheless, in many cases bore sporangia.

SOCIETIES AND ACADEMIES

LONDON.

Royal Society, December 8.—"Preliminary Account of the Nephridia and Body Cavity of the Larva of *Palæmonetes varians*." By Edgar J. Allen, B.Sc., University College, London. Communicated by Prof. W. F. R. Weldon, F.R.S.

The Green Gland, in a larva of *Palæmonetes* which is a few days old, consists of an end sac, which communicates by means of a U-shaped tube with a very short ureter, opening at the base of the second antenna. At the time of hatching, the gland consists of a solid mass of cells, without a lumen. In later stages the tube of the gland enlarges to form the bladder. The enlarged bladders of the two sides subsequently meet and fuse in the middle dorsal line, forming the nephroperitoneal sac described by Weldon and Marchal.

The Shell Gland is found in late embryos and young larvæ of *Palæmonetes*. It consists of a short renal tube, with a considerable lumen, which communicates internally with an end-sac, and opens externally at the base of the second maxilla.

Sections through the anterior region of the thorax of *Palæmonetes* show that the body cavity may be divided into four regions: a *dorsal sac*, surrounded by a definite epithelium, in which the cephalic aorta lies, but which does not itself contain blood; a *central cavity*, containing liver, intestine, and nerve cord; two *lateral cavities*, containing the proximal ends of the shell glands; and fourthly, the *cavities of the limbs*, which contain the distal ends of the same organs.

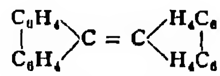
In late embryos of *Palæmonetes* solid masses of cells lie upon either side of the cephalic aorta. The dorsal sac is formed by the hollowing out of these masses of cells. Two lateral cavities are thus formed, which are separated by the aorta. The protoplasm of the cells lining these cavities, which is at first gathered into masses around the nuclei, then spreads out into a thin sheet, drawing away from the lower portion of the aorta, and causing the two lateral cavities to unite ventrally, and so form a single sac.

In the posterior region of the thorax the central and lateral cavities are similar to those of the anterior region, whilst dorsal to them the pericardial chamber lies. This chamber is separated from the central body cavity by the pericardial septum. The genital organs are situated immediately below the front end of this septum.

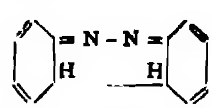
A comparison with the body cavity of *Peripatus* suggests the following relations. In the anterior region of the thorax of *Palæmonetes* the dorsal sac is homologous with the dorsal portions of the mesoblastic somites of *Peripatus*, and its cavity is a true cœlom. The central and lateral cavities, together with the cavities of the legs, represent the pseudocœle. In the posterior region of the thorax the cavities are all pseudocœlomic, and agree with those of the adult *Peripatus*.

December 15.—"Preliminary Note on the Relation of the Ungual Corium to the Periosteum of the Ungual Phalanx." By F. A. Dixey, M.A., M.D., Fellow of Wadham College, Oxford. Communicated by E. A. Schafer, F.R.S.

Chemical Society, December 1.—Prof. A. Crum Brown, President, in the chair.—The following papers were read:—The isolation of two predicted hydrates of nitric acid, by S. U. Pickering. The author announces the isolation of two crystalline hydrates of nitric acid, the monohydrate and the trihydrate, melting at $-36\cdot8°$ and $-18\cdot2°$ degrees respectively. In the case of either the melting-point is lowered by the addition of acid or water. The existence of these compounds was foreseen from an examination of the curves plotted from Bertholet and Thomsen's heat of dissolution values. This result is an important confirmation of the author's views.—Anhydrous oxalic acid, by W. W. Fisher. The best method of obtaining crystallized anhydrous oxalic acid is by allowing the hydrated acid to remain in contact with concentrated sulphuric acid for some months in a sealed glass tube. Oxalic acid is soluble in about 30 parts of cold sulphuric acid; the anhydrous acid dissolves with absorption of heat, whilst the reverse is the case with the hydrated acid. Anhydrous oxalic acid may be crystallized from nitric acid of sp. gr. 1·5. Oxalic acid may be completely dehydrated in a vacuum at 60°; the anhydrous acid is soluble in ethyl oxalate or glacial acetic acid, and separates from these solvents in a powdery form.—The production of orcinol and other condensation products from dehydracetic "acid," by N. Collie and W. S. Myers. The authors have obtained orcinol by the action of barium hydrate on dehydracetic "acid" or dimethylpyrone; on boiling a mixture of syrupy caustic soda and dehydracetic "acid," a true carboxylic acid is first produced, and, losing carbonic anhydride, yields orcinol. Among the products of the interaction of barium hydrate and diacetylacetone bright yellow needles melting at 180–181° are found; these probably consist of a naphthalene derivative $C_{11}H_{10}O_2$. Amidodehydracetic "acid," obtained in long needles melting at 192–196°, by the action of strong ammonium hydrate on dehydracetic "acid," readily yields dehydracetic "acid," on acid or alkaline hydrolysis.—Observations on the origin of colour and on fluorescence, by W. N. Hartley. It cannot be stated in general terms that colour is due to special methods of atomic arrangement; the statement may, however, be applied in a restricted sense to certain organic compounds, especially to those included in the class to which organic dye stuffs belong. It is pointed out that all open chain hydrocarbons exert a continuous absorption, the extent of which depends on the number of carbon atoms in the molecule. The condition of strain and instability existing in many coloured substances has been remarked by Armstrong; the author points out that all organic colouring matters are endothermic compounds, and considers this to be the physical cause of what Armstrong terms "reactivity" or "high potential." It is shown that anthracene is not colourless, but has a true greenish-yellow colour in addition to its fluorescence. A number of experiments on fluorescence are detailed, and the following conclusions drawn from them:—(1) Alcoholic solutions of quinine exhibit a beautiful, bright violet fluorescence. (2) Hydrochloric acid is not fluorescent. (3 and 4) Quinine hydrochloride and chloroform are feebly fluorescent, but without distinct colour. (5) Both hydrochloric acid and chloroform can extinguish those rays which are the cause of fluorescence in quinine. (6) Some alkaloids may be recognized by the degree and colour of their fluorescence. (7) Normal alcohols of the ethylic series and the fatty acids are fluorescent. (8) Glycerol has a violet fluorescence. (9) Benzene has a pale blue fluorescence, azobenzene a greenish-blue. (10) Rock crystal has a pale bluish-violet fluorescence, flint glass a strong blue, and crown glass a very brilliant blue fluorescence. (11) Substances which are not fluorescent in strong solutions may become so on dilution, particularly if they exert a very powerful absorption of the ultra-violet or invisible spectrum.—The origin of colour, V. coloured hydrocarbons and fluorescence: a reply to Prof. Hartley's observations on the origin of colour and of fluorescence, by H. E. Armstrong. If attention be paid to visibly coloured organic substances, it is a most remarkable fact that in those cases in which the "constitution" is fairly well established coloured substances are found to be all of one type. The author starts from this basis to inquire whether all coloured organic substances are not similar in type. Hartley's remark that all organic colouring matters are endothermic compounds has little importance in the present connection, inasmuch as the converse does not hold. The author contends that before admitting the fluorescence of many substances, *e.g.* alcohol and its homologues, every precaution must be taken to ensure their purity; instances in which easy explanation of the fluorescence of certain substances is possible are given. Hartley's observation that anthracene is coloured strongly confirms the author's hypothesis. Anthracene is fluorescent, and may be represented by a quinonoid formula, whilst its isomeride phenanthrene, which cannot be so represented, is colourless and non fluorescent. Furthermore, whilst intense colour is produced by "weighting" what the author terms the "quinonoid radicles" of anthracene by replacing the central hydrogen atoms by a halogen, no such effect attends the similar treatment of phenanthrene, dibromophenanthrene being colourless like the hydrocarbon. And yet anthraquinone and phenanthraquinone are coloured yellow and deep orange respectively. Reference is made to other coloured hydrocarbons, viz. carotin and the red hydrocarbon, $C_{26}H_{16}$, recently investigated by Graebe. The formula assigned to the latter by Graebe—



—is an improbable one; such a substance would be colourless. The author gives a possible constitution, and, for the present, proposes to call the compound "erythrophene." The yellow hydrocarbon, $C_{26}H_{18}$, obtained together with this, is possibly a diphenylated anthracene, and may be termed "xanthophene." The "quinonoid radicles" in both hydrocarbons are heavily "weighted," hence their strong colour. With reference to Hartley's statement that a very little shifting of the region of absorption determines the presence or absence of colour in a compound, it is contended that this shifting may be due to a special character of structure. The author then explains his views as to the manner in which the "quinonoid mechanism" conditions colour. He suggests that in quinonoid compounds there are two "colour centres" correspon ling to and expressed by the symbol $\supset$ in formulæ such as he has used in representing coloured substances. These centres co-operate in producing colour through interaction of the light waves which traverse them. Substances in which there are no such co-operating centres may absorb generally and selectively in "ultra" or "infra" regions of the spectrum, but without exhibiting "visible colour."—The origin of colour, VI. azobenzene, by H. E. Armstrong. Azobenzene, a highly coloured substance, is generally represented as Ph.N : N.Ph, a formula in disaccord with the author's hypothesis explained in the preceding paper. Moreover, the formulæ usually attributed to the colourless diazo-salts (Ph.N : N.Cl, for example) represent them as comparable in constitution with azobenzene. The behaviour of azobenzene towards bromine and other reagents leads the author to doubt the correctness of the conventional formula assigned to it, and to consider the following a more probable one:—



—The reduction products of dimethyldiacetylpentane, by F. S. Kipping. The author shows that dimethyldiacetylpentane, a diketone produced by the hydrolysis of ethyl dimethyldiacetylpimelate is converted by reduction with sodium in a moist ethereal solution into dimethyldihydroxynonane and a compound

which, judging from the manner in which it is formed, may be regarded as tetramethyldihydroxyheptamethylene

$$CH_2\langle\begin{matrix}CH_2 . CHMe & CMe & OH \\ & | & \\ CH_2 & CHMe & CMe & OH\end{matrix}$$

—The products of the interaction of zinc chloride or sulphuric acid and camphor (third notice), by H E Armstrong and F S Kipping The authors have previously shown that the crude product obtained on heating camphor with sulphuric acid or zinc chloride contains 1 2 . 4 acetylorthoxylene On oxidizing the oil remaining after the separation of the latter substance, a-methylglutaric acid is formed This acid being the characteristic oxidation product of the phorone obtained by distilling calcium camphorate, it is probable that a homologue of this phorone is present in the camphor product —The Griess Sandmeyer interactions and Gattermann's modification thereof, by H. E Armstrong and W P Wynne. In employing the Griess Sandmeyer methods for displacing the amido-group by halogens, the authors find that, in very many cases, much better results may be obtained by operating at relatively low temperatures instead of at the boiling point It appears also that the Gattermann process affords a larger yield than the Sandmeyer process, only because it is carried out at a lower temperature —Methods of observing the spectra of easily volatile metals and their salts, and of separating their spectra from those of the alkaline earths, by W N Hartley Persistent flame colourations of easily volatile metals, such as lithium, potassium, rubidium, cæsium, and thallium, may be obtained by heating beads of their fluosilicates, borates or silicates, on platinum wires in the Bunsen flame If the substance to be spectroscopically examined be converted into a borate, the spectra of the alkali metals may be first observed, and on subsequently passing hydrogen chloride into the flame, the spectra of the alkaline earth metals may be rendered visible —Manganese borate, its constitution and properties, by W N Hartley and H. Ramage Manganese borate, after drying *in vacuo* over sulphuric acid has the composition $MnH_4(BO_3)_2.H_2O$ On heating at 100° it loses one molecule of water, and at a red heat two molecules more of water are lost, leaving a salt of the composition $Mn(BO_2)_2$ From the rate of loss of water with rise of temperature the existence of a number of intermediate salts is inferred Manganese borate possesses a maximum of solubility in water at 18°, and a minimum at 80° This is probably due to dehydration of the compound having the composition $MnH_4(BO_3)_2.H_2O$

Anthropological Institute, December 13 —Edward B Tylor, President, in the chair —Mr. Arthur J Evans read a paper on the prehistoric interments of the Bahi Rossi caves near Mentone and their relation to the Neolithic cave burials of the Finalese He described the recent discovery of three skeletons in the cave of Barma Grande, and showed that the character of the sepulchral rites practised, the relics found, and the racial type of the human remains agreed with the earlier discoveries made by M Rivière and others in the same caves Mr Evans, however, opposed the theories that had been put forward as to the Palæolithic date of "Mentone Man" The bones of extinct Pleistocene animals and implements of the Moustier and Magdalenian types found in the cave earth above the interments proved nothing, for the simple reason that they were interments. No remains of extinct animals had been found in actual juxtaposition with the skeletons On the other hand the complete absence of pottery, of polished implements, and of bones of domesticated animals in this whole group of interments and the great depth at which they occurred proved that the remains belonged to a very early period. Evidence was here supplied of an earlier Neolithic age than any yet authenticated. Still the remains belonged to the Later Stone Age and to the days of a recent fauna Mr Evans compared some bone ornaments found with the so called hammer-beads of the chambered barrows of Scandinavia and the decorative system with that found on Neolithic pottery in northern Europe He further showed that interments of the same tall dolichocephalic race in a more advanced stage of Neolithic culture were to be found in the cave-burials of the Finale district further up the Ligurian Coast The physical form and the character of the sepulchral rites was essentially the same Only the skeletons were here associated with polished axes, pottery, and bones of domesticated animals. The direction from which the new civilising influences had come was indicated by imported shell ornaments from the southern and eastern Mediterranean , in the Mentone caves the imported shells were from the Atlantic In conclusion Mr Evans showed that the latter Finale interments exhibited forms of pottery and implements identical with those of the Italian terremare of the other side of the Apennines, and included ceramic shapes which seemed to be the prototypes of vessels found in the early Sikel tombs of Mycenæan age The Italic culture here revealed fitted on not only to that of the early pile-settlements of the Po Valley and the Lake dwellings of Switzerland, but might be traced to the Danube valley, to Thrace, and the Troad Amongst other parallel forms owl-like idols bearing a strong resemblance to those described by Dr Schliemann from the site of Troy had been found by Padre Morelli of Genoa in one of the Finale caves —Dr H Colley March read a paper in which he sought to prove that the peculiar features of Polynesian ornament are due to a mythography which is, in the main, a symbolism of origin and descent Thus regarded, unattractive and bewildering designs are resolved into emblems of divinity and demonstrations of lineage He traced the evolution and defined the attributes of Tiki, explained the nature of oromatuas and the meaning of unus, described the various methods of recording pedigrees, whether along a male or along a female line, and illustrated the mythical use of tapa and sinnet He discussed, as modes of origin, totemism, gemmation, and generation, of which Polynesian examples were given, tabulated the kinship of the superior gods, set forth in full the Tane cult, especially in relation to the axe and the drum, and endeavoured, in conclusion, to account for the development of the complicated Mangaian adze

EDINBURGH

Royal Society, December 5 —Sir Douglas Maclagan, President, in the chair —After an introductory address by the President, a note by Prof Cayley, on uniform convergency of series, was read —Prof Tait communicated a note by Prof P. H Schoute, of Groningen, on the locus of a uniformly revolving line, which always passes through a point moving uniformly round a circle, and which always lies in a normal plane passing through the centre of that circle The degree of the locus is found by an elegant and very simple method —Dr C Hunter Stewart gave notice of a paper on the further development of Kjeldahl's method of organic analysis. The carbon, as well as the nitrogen, present can be determined by the same analysis in the developed method, and much smaller quantities than formerly of the substance analyzed lead to results as accurate as those previously obtained —Prof Tait read a note on the division of space into cubes He gives a different, and more direct and short, solution by quaternions than that given by him some years ago

PARIS

Academy of Sciences, December 26.—M d'Abbadie in the chair —Thermal elevation under the influence of injections of soluble microbian products, by MM Bouchard and Charrin An elevation of temperature recalling that observed by Koch is produced in a marked degree in tuberculous patients by injections of the toxic substances secreted by the pyocyanic bacillus. —Vessels and clasmocytes of the hyaloid in the frog, by M. Ranvier —Observations of Holmes's comet (November 6, 1892) made with the great equatorial of the Bordeaux Observatory, by MM G Rayet and L. Picart, report by M Rayet.—Observations of Swift's comet (1892, I) made with the great equatorial of the Bordeaux Observatory, by MM. G Rayet, L Picart and F Courty, report by M Rayet —On the laws of dilatation of fluids at constant volume, coefficients of pressure, by M E H Amagat —Observations of Holmes's comet, made with the *equatorial coudé* (32 cm) of the Lyon Observatory, by M G Le Cadet —New experimental researches on the personal equation in transit observations, by M P Stroobant —On conjugate systems and couples of applicable surfaces, by M. A Petot —On infinitesimal deformation and Bianchi's associated surfaces, by M E Cosserat —On contiguous surfaces relative to the hypergeometrical series with two variables, by M Levavasseur —Test for the convergence of series, by M A. de Saint-Germain —Criterion of divisibility by any number, by M Fontés —On the motion of a particle in the case of a resistance proportional to the velocity, by M Elliott —General form of the law of vibratory motion in an isotropic medium, by M E Mercadier —Employment of springs in the measurement of explosive pressures. If errors due to the inertia of the moving parts of the indicator are to be avoided, the amplitude of the

tracing point must not exceed 1 mm in the case of pressures used in modern firearms. This necessitates careful reading with a microscope.—On the decrease of temperature of the air with the elevation, by M. Alfred Angot. Experiments conducted on the Eiffel Tower indicate a decrease for each 100 m., between the soil and a height of 160 m. ranging from 0·6° in December to 1·46° in June. Between 160 m. and 302 m. the decrease per 100 m. ranges from 0·64° in February to 0·96° in October. At 300 m. the decrease per 100 m. is on the average 0·5° in winter, 0·6° in autumn, 0·7° in spring, and 0·8° in summer.—On the temperature of the electric arc, by M. J. Violle. From calorimetric measurements made with a portion of the arc light carbon detached from the hottest part during the passage of the current, the temperature of the arc, *i.e.* that of the volatilization of carbon, appears as 3500°, assuming the carbon to have its theoretical specific heat, 0·52, at the higher temperatures. This temperature of volatilization is constant, whatever the power employed.—Remarks on high temperatures and the vaporization of carbon, by M. Berthelot. The vapour tension of carbon is quite appreciable even below volatilization, which involves the reduction of a polymer to the monomolecular state, thus in reality representing a chemical process. Higher temperatures than that of the arc can be attained by purely chemical means, such as the explosive combustion of a mixture of oxygen and cyanogen.—On the equality of velocities of propagation of electric waves in air and along conducting fibres, verified by the example of a large metallic surface, by MM. Ed. Sarasin and L. de la Rive.—On nets of electric conductors; reciprocal properties of two branches, by M. Vaschy.—On the enfeeblement of electromagnetic oscillations with their propagation and their subsidence, by M. A. Perot.—Determination of the coefficients of self induction by means of electrical oscillations, by M. P. Janet.—Doppler Fizeau's method, exact and approximate formulæ, evaluation of the error involved, by H. de la Fresnaye.—Magnetic properties of oxygen at different temperatures, by M. P. Curie. A series of measurements with oxygen compressed to 5 and to 18 atmospheres respectively gave identical results at temperatures between 20° and 450°. Within this range, the volume coefficient of specific magnetization of oxygen varied inversely as the absolute temperature. The volume coefficient of magnetization of air at the ordinary pressure and at temperature t is given by $10^6 k_t = 2760 \times T^{-2}$, where T is the absolute temperature.—On the rotatory power of quartz at low temperatures, by MM. Ch. Soret and C. E. Guye.—On the fusion of carbonate of lime, by M. A. Joannis.—Ammoniacal compounds derived from ruthenium sesquichloride, by M. A. Joly.—On an iodo-sulphide of phosphorus, by M. L. AMERICAN MECHANISM

Modern Mechanism Edited by Park Benjamin, LL B , Ph D (London and New York Macmillan and Co , 1892)

IN order to appreciate this volume thoroughly, it is necessary in the first instance to consider the reason for its existence Appleton's "Dictionary of Engineering," an American book, was published in the year 1851, and was the first to gather in cyclopedic form descriptions of products of American mechanical industry Some thirty years afterwards it became necessary to bring the work up to date, and its complete reconstruction was decided upon The editor observes that no previous work of a technical character had so signally, and so quickly, demonstrated its own usefulness, it rapidly became a recognized standard of American mechanical practice Owing, however, to the great progress made in mechanical invention, and the marvellous rapidity with which electrical science has advanced, a new record of the results has become necessary, and hence the present volume

The list of contributors includes the names of eminent men, well known in this country for their high attainments in the different branches of mechanical and electrical engineering, forming a sure guarantee that the information to be gleaned from the pages is valuable and accurate It would be impossible in the space at our disposal to notice more than a small part of the contents Some interesting information is to be found on the subject of aerial navigation, more particularly the interesting experiments being carried out by Mr Hiram S Maxim Commenting on Prof Langley's statement, that with a flying machine the greater the speed the less would be the power required, Mr Maxim says "In navigating the air we may reason as follows if we make no allowance for skin friction and the resistance of the wires and framework passing through the air—these factors being very small indeed at moderate speeds as compared to the resistance offered by the aëroplane—we may assume that with a plane set at an angle of 1 in 10, and with the whole apparatus weighing 4000 pounds, the push of the screw would have to be 400 pounds Suppose, now, that the speed should be 30 miles an hour, the energy required from the engine in useful effect on the machine would be 32 horse-power (30 miles = 2640 feet per minute, $\frac{2640 \times 400}{33,000} = 32$) Adding 20 per cent for slip of screw, it would be 38 4 horse-power Suppose, now, that we should increase the speed of the machine to 60 miles an hour, we could reduce the angle of the plane to 1 in 40, instead of 1 in 10, because the lifting power of a plane has been found to increase in proportion to the square of its velocity A plane travelling through the air at the rate of 60 miles an hour, placed at an angle of 1 in 40, will lift the same as when placed at 1 in 10, and travelling at half this speed The push of the screw would therefore have to be only 100 pounds, and it would require 16 horse-power in useful effect to drive the plane Adding 10 per cent for the slip of the screw, instead of 20, as for the lower speed, would increase the engine power required to 17 6 horse-power These figures, of course, make no allowance for any loss by atmospheric friction Suppose 10 per cent to be consumed in atmospheric resistance when the complete machine was moving 30 miles an hour, it would then require 42 2 horse-power to drive it Therefore at 30 miles an hour only 3 84 horse-power would be consumed by atmospheric friction, while with a speed of 60 miles an hour the engine power required to overcome this resistance would increase eightfold, or 30 7 horse-power, which, added to 17 6, would make 48 1 horse-power for 60 miles an hour "

Mr Maxim goes on to observe that his experiments show that as much as 133 pounds can be carried with the expenditure of 1 horse-power, and under certain conditions as much as 250 pounds It will be evident, therefore, that the question of motors is all important, and that the total weight per horse-power developed must be as low as possible It is stated that the greatest force can be obtained from a compound high-pressure steam engine using steam at 200 to 350 pounds pressure, and such engines have been constructed weighing 300 pounds , the horse-power of these engines is not stated

It will be interesting to watch the outcome of these investigations They indicate that much information is being accumulated, and that sooner or later a successful aerial machine will be forthcoming

The question of armour plates has long vexed the soul of the British Admiralty , many very costly trials have been carried out in order to find the most suitable plate for the service All these data have probably been known in the States, and that country must have benefited by them Under this heading we find much information in the book, American experiments being quoted and illustrated Naturally, the Americans wish to make their own plates, and wisely endeavour to do so by rolling only, to do without the heavy expense of forging These experiments show that the high-carbon nickel Harveyed plate is undoubtedly the best plate ever tested As a result of these trials, orders have been placed for plates for the cruisers under construction An excellent full-page engraving is given of the U S armoured battle ship *Indiana*, and to judge by the blackness of the smoke she is not using Welsh coal ! The article on steam boilers is well written, and very complete, containing much useful information Among the many types of boilers illustrated there is a good print of the Yarrow torpedo boat boiler We miss however, the familiar Thornycroft boiler, and note an American water tube-boiler for fast launches very like the Thornycroft in the arrangement of the tubes

The boilers for marine purposes are purely of the British type, and there is nothing of importance to note on this subject beyond the many experimental results recorded.

Further on in the book there is an interesting description of railway-car heating We are told that car-heating, in the usual acceptance of the term, has come to mean the heating of railway cars by the use of steam from the locomotive This is important, showing as it does the direction in which American railway companies are moving in the solution of a problem at present occupying the best attention of engineers in this country Gener-

ally, we are told, the systems consist of a separate hot-water circulating system in each car, in connection with a heater, fed by steam from the locomotive, by a continuous train pipe running the length of the train, and coupled together between the cars by flexible hose-pipes and universal couplings; the Sewall steam coupler being generally used. Another important railway necessity is the continuous brake Under this heading the latest form of Westinghouse quick-action automatic brake is described In the original design the brake is applied by the engine-driver allowing a little air to escape from the train pipe, lowering the pressure, and thus applying the brake by the automatic action of the triple valves It is evident that the vehicle next the engine will feel this reduction first, and its triple valve will work before that on the second vehicle, and so on On trains of ordinary length this very slight difference in time between the brake's application on each vehicle is of little consequence, but when this automatic brake is fitted to a long goods train it becomes a serious matter The length of a goods train of fifty American cars is 1900 feet, and the brake should act instantaneously to be perfect The new triple valve is itself designed to discharge air from the train pipe, so on the driver opening the driver's valve, allowing air to escape to apply the brakes, the reduction of pressure operates the triple valve on the first car; this lets out more air, and so on through the train, the brake on the last car, 1900 feet away, being operated in 2 5 seconds after that on the first car

The vacuum automatic brake is not described or illustrated This brake is now being more and more brought into use, and for general purposes it appears to be simpler and less liable to get out of order than its competitors

A considerable part of the volume is taken up with the applications of electricity, for lighting and motive power purposes generally On dynamo electric machinery much has been written and well illustrated. The reader is taken step by step from the rudiments of the subject to its latest applications, from a description of armatures to the arrangements of the field-magnets, then to the varying designs of dynamos, including most of the known machines The same may be said on the treatment of the electric motors Under the head of the transmission of power there is more useful information to be found, this being all the more interesting, because of the proposed use of electricity as a means of transmitting some of the power of Niagara to distant towns There is, however, something wanting under the heading of electrical measuring instruments. The only ones mentioned are Weston's volt and ammeters At the present time the street tramways of this country are in an uncertain stage as far as motive power is concerned; horse-power is admittedly expensive, the steam locomotive seems to have got into disrepute, the cable and electric traction appear to be struggling for the mastery It is interesting therefore to read the memoir on electric traction in this volume The accumulator system is just described, but the overhead cable or trolley system takes up the greater part of the space, so it is safe to assume that the latter is more generally in use, the principle of which is as follows. the current starts from the positive brush of the dynamo, passing out to the main conductor, suspended over the middle of the track, and along this conductor until it reaches the point where the trolley of one of the motor cars is in contact Here it divides, and a portion passes down through the trolley to the motors, and thence to the rails forming a return lead to the negative brush of the generator The main portion of the current passes on to feed other cars upon the line in the same manner, each car taking the quantity of current necessary to develop the required power There are at the present time nearly 500 electric railways in America, and taking the results of twenty-two electric trolley lines, we find that the expenses vary per car mile from 22 99 cents to 7·89 cents, the highest and lowest respectively A view is given of the electric street railway at Washington, D C, the overhead conductors being not at all unsightly

On electric welding there is also much information, the Thomson process being very fully described It consists briefly in completing the electrical circuit through the parts to be welded together, the resistance being sufficient to heat the parts so as to weld them, this being assisted by pressure

The Bernado process is not described, in this process the work to be welded is connected to one terminal of the dynamo The positive terminal being connected with a carbon rod, held in a portable insulated holder, the carbon rod is then placed on the work, and immediately withdrawn slightly, thus forming an arc, where the metal melts, and with skill much can be done.

The locomotive practice in America has long been of interest to locomotive engineers in this country, owing to the many differences in design and practice A very good *résumé* of American practice is to be found in the memoir under this heading A useful table is given showing a few leading dimensions, weights, &c, of typical engines in use Take, for instance, the express passenger engine, a four-coupled bogie engine, the cylinders being 20 inches in diameter and 24 inches stroke The driving or coupled wheels are 72 to 78 inches in diameter The weight on coupled wheels is 75,000 pounds (33 48 tons), the total weight of the engine being 116,000 pounds (51 78 tons), and that of the tender 72,000 pounds (32 14 tons Comparing these data, we find that the American engine is heavier than an 18×26 cylinder British engine and not so powerful, assuming equal steam pressures, the tender is light in a similar comparison, probably carrying less water The reputed weight of trains hauled given in the table is of little use, because the speeds are not given, and for this reason comparisons cannot be made

The paragraph on locomotive boiler construction is far too short, many interesting details might have been added It is stated that the circular smoke-box tube plate is a conspicuous difference between the practices of the two countries, being purely American, whereas the Midland Railway Company have, amongst others, used the arrangement for some time Owing to the enforced use of anthracite coal in certain parts, many peculiar designs of locomotive boilers have been used, the Wootten boiler being probably the most common All, however, have particularly large grate areas, which, in the case of the Wootten, may in some cases exceed 76 square feet, or four times the area of the grate of

recent British engines. An illustration is given of an engine of this type, as well as a full-page engraving of a compound locomotive with a similar boiler. This compound is very different from the Webb or Worsdell engines common in this country, being the design of the superintendent of the Baldwin Locomotive Works. The cylinders are outside the frames—there are two on each side, viz. one high-pressure and one low-pressure. The distribution of the steam being effected in each pair by one piston valve, each pair of pistons is connected to one crosshead, coupled in the usual way to the wheels.

A compound engine of the "Webb" type is also illustrated. This engine was constructed to Mr. Webb's designs in this country for the Pennsylvania Railway in 1889. It is stated that the results of experiments showed a saving of fuel over the ordinary engine of from 20 to 25 per cent.

This book is so full of interesting matter of so varied a nature that it would be possible to prolong this notice far beyond the space available. Take, for instance, agricultural machinery; the Price ploughing outfit is typical of the rest, consisting of a traction engine drawing four gangs of three ploughs, the twelve ploughs cutting eleven feet wide. The subject of milling tools is also of interest, because it is only during the last few years British engineers have used this means of shaping metals, the system having been brought into general use in the States.

Under the head of the manufacture of steel all the usual processes are described. We are informed that the Whitworth compression process is only partly successful in the formation of sound ingots; with this statement we cannot agree; the Whitworth steel ingot after compression is certainly sound throughout.

Taking into consideration the great mass of information contained in the 900 odd pages of this work, and the general excellence of the matter accumulated, it is only just to congratulate the editor on the completion of a work which must prove useful to many, and which should find a place in all technical libraries. The volume goes far to describe modern American mechanism, exhibiting the latest progress in machines, motors, and the transmission of power.

SEEDLINGS.

A Contribution to our Knowledge of Seedlings. By the Right Hon. Sir John Lubbock, Bart., M.P., F.R.S., D.C.L., LL.D., with 684 figures in text. In two volumes. (London: Kegan Paul, Trench, Trubner and Co., Ltd., 1892.)

SEEDS and seedlings have occupied the attention of Sir John Lubbock for a somewhat lengthened period. They have formed the subject of various communications, on his part, to the Journal of the Linnean Society and other publications. In the present volumes, modestly styled a "contribution," he gives us the details upon which his inferences have been founded.

The physical and chemical aspects of germination are entirely passed over, but the morphological phenomena are treated with a fulness never before attempted. The author has availed himself of the resources put at his disposal by the authorities at Kew, where the larger proportion of the seedlings described were grown expressly for the purpose. The Natural History Museum and the Cambridge Botanic Gardens have also been requisitioned, and much help has been rendered by capable assistants, whilst the services of Sir Joseph Hooker and Mr. Rendle, in looking over the proof sheets, are duly acknowledged. A work of such dimensions, crowded with detail, could hardly have been produced without such zealous co-operation. Nevertheless unity of plan and uniformity of treatment are conspicuous throughout, and thus comparison is readily effected.

Some previously published papers in the Journal of the Linnean Society, dealing with the causes which determine the form of leaves and cotyledons, are reprinted as the introduction to the treatise. The conclusion therein arrived at is that the form of the embryo, and especially that of the cotyledons, is essentially influenced by the form of the seed. On p. 78 the author begins the detailed examination of seedlings taken from almost all the orders of flowering plants. Five hundred and thirty succeeding pages in the first volume, and five hundred and eighty-eight in the second volume, are thus occupied. This little bit of statistics will serve to show the amount of detail which is contained within these volumes. The plan adopted is to give, first of all, a general sketch of the principal modifications exhibited by the fruit and seed in each order. Then follows a more detailed description of the seed and of the seedling plant in various representatives of the order. As these descriptions are identical in plan throughout, they are of great value to the student of comparative morphology. Naturally some orders are much better represented than others, but sometimes the omissions are rather unfortunate. In the genus Araucaria, for instance, seedling representatives of which are common in botanic gardens and nurseries, the diversities in the form of the seedling and in the mode of germination are very remarkable. "Characters" derived from the seedling plant have been recognized as of the highest importance for classificatory purposes since the time of John Ray (1682–1703).[1]

But whilst this is generally the case, such extraordinary exceptions as that mentioned in Araucaria are very noteworthy, and not less so because the genus in question is one of the very oldest of which fossil botanists have cognizance.

Myrtaceæ and Sapindaceæ are remarkable for the extremely diverse character of the embryo in different genera, and of which due note is taken in Sir John Lubbock's book. In Rosaceæ, on the other hand, the diversity is much less, nor is there any important morphological difference in the seedlings of the great order Compositæ, and scarcely more in Umbelliferæ, so far as they are known. These are facts of great significance with reference to the theories of inheritance and relative antiquity of groups.

[1] It may not be without interest to cite what Ray says on this matter:—"Floriferas dividemus in *dicotyledones* quarum semina sata binis foliis anomalis, seminalibus dictis, quæ cotyledonum usum præstant, e terra exeunt vel in binos saltem lobos dividuntur, quamvis eos supra terram foliorum specie non efferant; et *monocotyledones* quæ nec folia seminalia bina efferunt nec lobos binos condunt." Thus Ray not only recognised the presence of one or of two cotyledons, but also their nature and their epi- or hypogeal condition. As Ray has been mentioned, it is certainly not inappropriate to allude to Grew also, for the first chapter of his "Anatomy of Plants" (1682), and the whole of the fourth book is devoted to the seeds and seedlings, and in perusing them the reader will perceive that Sir John Lubbock has in a few cases been anticipated by his celebrated predecessor.

The gradual evolution of the perfect plant from the seedling is indeed a subject of great interest to the phylogenist, although it is difficult—nay, impossible—to separate those appearances which are merely hereditary from those which are the result of varying outward conditions, the more so because analogous conditions must have influenced the ancestors in past times even as they affect their successors now

Amid such a mass of detail it is difficult to pick out points worthy of special note We select two only out of many scores that might be mentioned Some Onagrads are remarkable for the intercalary growth which takes place in the cotyledons, of which several illustrations are given in Sir John Lubbock's book They call to mind the experiments of the late Prof Dickie, who, by suppressing the plumule of seedling castor-oil plants, succeeded in inducing the cotyledons to continue their growth and to assume dimensions much greater than that which is habitual to them

The small tubercles on the root of *Myrica californica* (vol ii p 523, Fig 663) have, so far as we know, not previously been observed The author compares them to those found on *Alnus cordifolia*, and it would be interesting to ascertain whether these outgrowths are caused by an organism analogous to *Schinzia alni*, as described by Woronin, or to that which induces the peculiar tubercles on the roots of Leguminosæ, recently studied by Prof Marshall Ward

Monocotyledons generally have been rather badly treated by the author, although such genera as Potamogeton, Aponogeton, Orontium, and other Aroids, and Palms (of which not a single illustration is given) would have furnished examples at once interesting and easily accessible

The work includes nearly seven hundred illustrations, faithfully executed, and very valuable to the student The bibliography, in spite of its occupying no fewer than thirty-eight pages, is the weak part of the book. Some of the most important references are omitted, and whole series of species whose mode of germination has been recorded and some times figured, have been passed over This only shows how colossal has been the task which Sir John Lubbock has set himself We do not think the worse of the sun for having a few spots on his disc, nor are botanists at all likely to disparage this work because further research might have added a few more illustrations As it is, it forms one of the most substantial and important contributions to botanical literature that have ever emanated from the press It must continue to be a standard book of reference for generations, and it will, we hope, stimulate observers, according to their several opportunities, to prepare similar monographs on the various organs of plants.

MAXWELL T. MASTERS

EPIDEMIC INFLUENZA

Epidemic Influenza a Study in Comparative Statistics. By F. A. Dixey, M A., M D (London Henry Frowde and H. K. Lewis, 1892)

AFTER an epidemic disease has visited a country, when the pathologist and practical physician have had their say, there still remains the work of the statistician to be done. It is his province to sum up the results of the visitation in the clear light of hard figures, and to trace its onset and decline in mathematical curves Such work is of value in more than one direction It preserves for future generations a definite record of an epidemic of greater precision than the impression left on the mind of the physician it enables a comparison to be drawn between our own experience and that of other countries by the sifting and sorting of facts which it necessitates it may lead to the discovery of relationships with allied diseases which may prove of no small value to the pathologist

This work has been done for influenza by Dr Dixey in a very thorough and painstaking manner from the material collected under the supervision of the Registrar-General It says much for the completeness of our registration system in London, that it is possible to compile from them such tables and curves as those with which we are presented in this work, nor are such materials available from any other city in Europe The only cities whose statistics have been found by Dr. Dixey sufficiently accurate for comparison with our own are Paris and Berlin

Dealing first with the epidemic of 1889-90, he shows in Table 1 the rise and progress of the disease in London, as indicated by the weekly returns of fatal cases, grouped according to the seven age periods adopted in the official returns Table 2 gives us, so far as the returns of the period permit, the similar figures for the epidemic of 1847-48 The similar characters of the two epidemics are strikingly illustrated: in both we see the same extreme suddenness of rise, and the same features of decline, rapid at first, but becoming gradually slower during the succeeding months In the next two tables are included similar figures for Paris and Berlin, and in these, and in Table 5, the author gives an analysis of the meteorological conditions accompanying the rise and fall of the epidemic in the three cities These are of interest as showing how little influence the weather had on the course of the disease as a whole

In the tables which follow—which are perhaps of greater interest than any of the others Dr Dixey has compiled—the effects which influenza has exerted on the mortality from other diseases in London and other cities are shown These effects are of two kinds influenza may aggravate the mortality of pre-existent disease such as phthisis or heart disease, or diseases such as bronchitis or pneumonia may occur as complications of influenza and swell its death-roll It is interesting to observe that whereas in 1847-48, which was in all respects a more fatal epidemic than that through which we have just passed, bronchitis showed the most extreme departure from the normal mortality, pneumonia holds that place in the late epidemic, while bronchitis falls into the second rank. In this connection may be mentioned a point of much interest illustrated in Tables 10, 11, and 12, which deal with the age incidence of influenza and its concomitant diseases It is possible to draw curves showing the special age incidence of each, and each curve has its own special features. Now during an influenza epidemic the pneumonia curve is found to be modified so as to take on some of the characters of the influenza curve, thus affording corroborative evidence of a conclusion already reached both in this country and in

Germany, that influenza may occur sometimes as an apparently primary pneumonia

The remaining tables deal with the data afforded by the epidemics of 1891 and 1892 in this country and abroad That of 1891 is shown to have been much more fatal, especially at advanced periods of life, than that of 1890, while that of 1892, here treated of with less fulness than the preceding, seems to have been of still greater severity Those who would follow Dr Dixey into the details of these outbreaks must study the work for themselves It is a contribution to statistical literature of very great value, and will save an infinity of labour to those engaged in the study of influenza.

A word of praise must be bestowed in conclusion upon the graphic charts with which the tables have been illustrated, those in particular which deal with the mortality curves from influenza and its allied diseases These have been calculated and mapped out as percentage deviations from the mean, and show the main facts at a glance in a way which mere columns of figures fail to do Those also which illustrate the age incidence of the diseases in question are of great value

OUR BOOK SHELF

An Elementary Text-Book of Hygiene By H Rowland Wakefield (London Blackie and Son, 1892)

THE appearance of yet another elementary text-book upon the subject of Hygiene has the effect of aggravating the *embarras de richesses* which already obtains in this department of study, one is therefore justified in questioning the utility of the present volume, and on reading in the preface that it is adapted to the requirements of the Science and Art Department, there is all the more matter for surprise at its appearance in the face of three other publications—each better than the present—which have been written to meet the same end

The manual is well printed and concisely written, and a surprising amount of matter is condensed within its tiny compass This latter fact, however, is not entirely a matter for congratulation, for apart from making the book "dry reading," it must have the effect of rendering it in many places difficult of comprehension to those for whom it is intended, *i e* those who approach the subject with no prior knowledge whatever

And thus it comes about, that in less than 200 small pages the whole range of Hygiene is surveyed, including chapters upon Eyes and Sight, School Hygiene, House Sanitation, Personal Hygiene, Parasites, Infectious Diseases, Accidents and Injuries

Though the material given has been on the whole well selected and carefully compiled, the work is a little uneven, one finds seventy-three pages devoted to "food," whereas "water" is dismissed in seventeen, and "sewage and its removal" in eleven.

Here and there is evidence of the fact that the author is not of the profession to which Hygiene holds a filial relation, and that he was not quite at home with some of the departments of the subject—even in their elementary form—which he had set himself the task of handling, the very few errors and ambiguities which this fact is accountable for, are, however, too trivial to much affect the general accuracy of the book

The small work will doubtless suffice for the examination requirements of those for whom it is intended, but the brevity and superficiality of treatment which is so frequently apparent within its pages, will not justify one in recommending it to those who wish to lay a good and useful foundation for a study of the science of Hygiene.

Ostwald's Klassiker der Exakten Wissenschaften Nos. 38–40 (Leipzig W Engelmann)

WE are glad to note the addition of three volumes to this admirable series No 38 is the second part of the original account of the photochemical researches of R Bunsen and H. E Roscoe (1855–59) The other volumes are translations of a paper by Pasteur on the minute organic bodies in the atmosphere (1862), and of papers by Lavoisier and Laplace on heat (1780 and 1784) In all the volumes there are figures in the text

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Geographical Names

AS the names of places given to the public with the authority of the Geographical Society of London are very apt to be accepted by geographers and be ultimately inserted in atlases and works on geography, I have to call attention to the paragraph "Nomenclature of the Karakoram Peaks," under "Geographical Notes," p 857, in the December number of the Proceedings of the R G S, 1892, which I have lately read It is to be regretted that so much reliance and importance has been placed on what a native drew on the sand, and the names he gave to various peaks Natives are not always to be depended upon, not even when the topographical features are in sight, and unless verified from other and independent information, the names they give cannot be implicitly trusted and placed on record, as is so well exemplified in this case The traveller must also have a considerable knowledge of the native languages or he may be very much misled As fortunately I know both the places bearing the names given for two very conspicuous peaks, it may not be too late to prevent these names thus put forward from being accepted and perpetuated "Skeenmung" or "Skinmang" is the name of a comparatively level piece of somewhat grassy ground at the great bifurcation of the Punmah Glacier, the name itself is expressive and is derived from "*Skeen*" an ibex, and "*Mang*," a level place in Balti = *Marg*, Kashmiri, *Maidan* Hindustani—which disposes of it as a likely designation for a peak

Next we have "Chiring" given as the name of K2, the second highest peak in the Himalayas, quite as inaccurate, for it happens to be the name of another camping spot or bivouac at the end of a spur and about halfway between Skeenmang and the Mustakh pass, as used about the period I was there (1860). It is situated just above a very narrow part of the glacier, where its action is most marked on the rocky sides "*Chirna*" in Hindustani is to rend, tear, and Chiring Gause is the name of all that portion extending six miles up to the main watershed

Shalford Park, Guildford, January 7

The Weather of Summer.

THE number of days with rain, in summer, at Greenwich, during most of this century, has been subject to a pretty regular fluctuation The curve (from 1825) having been smoothed by means of five-year averages, we obtain that shown in the diagram And putting with it a curve of sun-spots, we find a strikingly definite correspondence (somewhat "lagging" in character) throughout at least four of the sun spot cycles, the rain day maxima coming soon after the sun-spot maxima, and rain day minima soon after sun-spot minima In recent years, however, the curves appear to have got out of step (*so to speak*) with each other; so that, *e.g.* we find a rain day *maximum* in 1880, two years after the sun-spot *minimum* of 1878, and a rain day *minimum* in 1885, two years after the sun-spot *maximum* of 1883.

I do not remember to have seen the facts of our summer weather put in this way. But it is well known that, in the discussions which arose some time ago about sun-spots and rainfall, there appeared some reason to believe that in the period of

those four earlier sun-spot cycles, at least, we had had, on the whole, wetter years about sun-spot maxima than about the minima. A good deal was written on the subject (as your own columns show) in the seventies, and the data used seem to have been generally those of annual rainfall Of late, apparently, the matter has attracted less notice, for the reason (I suppose) that the correspondence referred to has not been maintained, and recent facts have seemed rather against the theory of a causal relation between the two orders of phenomena

Thus the teaching of the curve here given appears to harmonize, in general, with known facts about annual rainfall. I do not propose to try and weigh the data so far as they may be considered to favour the theory just indicated (earlier and greater part of the curve), nor the data which may be considered adverse (in the short, later part) It seems to me that the curve may be usefully studied *per se*, apart from any relation to sun spots. Thus we might note the fact that all those maxima where our summers have got to a turning point from wet to dry have been quite near the beginnings of the decades The dates are 1830, 1839, 1850, 1861, and 1880 The curve ends at 1890 (the final point representing, of course, 1888–92), and the position of this point, together with the date, seem to warrant our

Smoothed curve of rain days in Summer at Greenwich, with curve of Sun-spots

looking for an early descent of the curve, and a commencing series of (on the average) drier summers than we have had lately

We might also note that the minima of the curve have ranged from the fives to the eights. Thus we have, 1827, 1835, 1845, 1857, 1868, 1885 Should the recurrence continue, we might look for the next minimum about 1895–1898 Of course there may be difference of opinion as to the strength of the presumption here afforded for such a forecast, and no good reason is offered (beyond experience) why the curve should now take the course roughly indicated.

It is not at variance with the above view that there is reason, it would appear, to anticipate soon a series of wetter *years* In an article contributed to the *Times* of October 22 last year (cited in NATURE, vol xliv. p 630) Mr. Symons says · "There is no doubt that since 1887, at all events, the rainfall over England has been much below the average, and a consideration of all the facts leads to the conclusion that such a period of scarcity is very likely to be followed by one of abundance, and that the coming few years will probably be more rainy than those recently experienced, although possibly the increase will not occur in the summer months—at a time when it would be most noticed "

A B M

"Aminol"

MY attention has only now been called to the letter of Dr Klein, which appeared in NATURE, *ante*, p. 149.

To the remarks referring to "Aminol" (with Periodate I am in no way concerned) I desire, with your kind permission, to make the following reply, as they contain inaccuracies which, if not corrected, must do me injury

The samples of "Aminol" alluded to by Dr Klein were sent by me to a number of medical practitioners who had kindly consented to give it a trial. The strength of the samples was 1 in 5000.

Dr Klein has carried out between September, 1890, and March, 1891, five separate consecutive series of experiments with "Aminol," with the object of testing its applicability to the treatment of certain external disease processes His results are recorded in a report, the summary and conclusions of which were published last year with his full approval The strength of solution employed in the first four series (which were only of a tentative nature with a view to arrive at a proper strength of solution for practical application) was 1 in 6000, in the fifth series a solution of the strength of 1 in 600 was used. Dr Klein's letter leads one to suppose that he operated only with the latter strength

The pathogenic germs selected for testing the power of the disinfectant were spores of *Bacillus anthracis*, sporeless *Bacillus anthracis*, *Staphylococcus aureus*, *Bacillus diphtheriæ*, and *Streptococcus erysipelatis*. Amongst the results obtained with the solution of the strength of 1 in 6000 his report mentions the following: In Series IV, "On *Staphylococcus aureus*, which may be taken as the most resistant microbe amongst those associated with surgical and other external disease processes, the "Aminol" solution (1 in 6000) did produce an effect, though a limited one, after two hours already, and after twenty four hours destroyed the microbes" In Series I - "'Aminol' solution (1 in 6000) kills the *Bacillus diphtheriæ* in two hours This was confirmed in Series III" In this connection it deserves to be noted that I possess already ample evidence, which will be published in due course, of conspicuous successes obtained in practice not only with the solution of the strength of 1 in 5000, but also with dilutions of the same, even to 1 in 20,000

Dr Klein's statement of the results which he obtained with "Aminol" in the strength of 1 in 600 is misleading He says "Spores of *Anthrax bacilli* remained unaffected after eight hours, only after an exposure of twenty-four hours did the number of living spores decrease, but some escaped disinfection even after so long an exposure Now what are the facts? I quote from Dr Klein's report —

"Spores of *Bacillus anthracis* after 1, 2, 8, and 12 hours	good growth
"Spores of *Bacillus anthracis* after 24 hours	growth reduced from 100 to 6"

Is it putting the case fairly or even clearly, seeing that no tests were made between twelve and twenty-four hours, to say "only after twenty four hours did the number decrease," and seeing that only 6 per cent remained after twenty-four hours? Is not that a decrease practically amounting to disinfection? Would it be extravagant to assume that the insignificant percentage remaining would be eliminated after a very little longer exposure (say another hour), and is there any doubt that a solution of the strength of 1 in 500 or 1 in 400 would have accomplished complete disinfection in a much shorter time than twenty four hours? But in order to illustrate the significance of the results actually obtained with this solution of the strength of 1 in 600, let us see which other disinfectants can kill anthrax spores in twenty-four hours. I quote from "Koch on Disinfection," abstracted and translated by Whitelegge, published by the New Sydenham Society ·—

(1) "For practical purposes a disinfectant should not require much longer than twenty-four hours"

(2) "Except chlorine, bromine, and iodine, only mercuric chloride, osmic acid, and potassic permanganate (5 per cent) destroyed anthrax spores within twenty four hours Since a 5 per cent solution of permanganate is inadmissible for disinfection in bulk, and osmic acid is out of the question, we have left only mercuric chloride and iodine, bromine, and chlorine"

The strengths in which the above-named substances succeeded in destroying anthrax spores in twenty-four hours are stated in Koch's tables thus.—

Permanganate,	aqueous solution	5 per cent	(1 in 20).
Bromine	,,	2 ,,	(1 in 50).
Chlorine	,,	?	
Iodine	,,	?	
Mercuric chloride	,,	1 per cent	(1 in 100).
Osmic acid	,,	1 ,,	(1 in 100).

Now put against this the fact, quoted above, that Dr Klein found "that 'Aminol,' strength 1 in 600, killed 94 per cent of anthrax spores in twenty-four hours," and further (I am quoting his report again), "that this solution is a perfectly harmless fluid as regards the human organism; therefore no undesirable disturb-

ances could ensue owing to its being absorbed, this is well known to be the fact with some antiseptics, as in carbolic acid applications or in the use of perchloride of mercury."

Does not all this clearly establish the claim of "Aminol" to be called not only a true disinfectant, but a most potent and a most safe one at the same time?

But with all this (I mean what relates to its effect on anthrax spores) its application in medical and surgical practice has nothing to do, unless it be to demonstrate its comparative potency, for, as Dr. Klein himself points out in his report, "The spores of *Bacillus anthracis* may be left out of consideration, as they do not occur in the living body, under these conditions the *Bacillus anthracis* is always sporeless, a malignant carbuncle of the skin contains the *Bacillus anthracis* only in the sporeless state, and in infection with anthrax generally the bacilli are always in the sporefree state both in the blood and in the tissues."

What is of real importance in practice is the effect of "Aminol" on the other pathogenic germs on which Dr Klein has tested it. And here again his letter states the case in a manner which is apt to mislead, "*Anthrax bacilli*, *Staphylococcus aureus* and others were destroyed, but only after a lengthy exposure"

Now what does his report say? "Series V From this series it will be seen, therefore, that the solution used in the same (1 in 600) acted very differently from that used in the previous experiments (1 in 6000) inasmuch as the *Staphylococcus aureus*, which was not killed heretofore in eight hours, was in this instance completely disinfected in that time, and was considerably reduced even in one hour The sporeless *Bacillus anthracis*, *Bacillus diphtheriæ*, and *Streptococcus erysipelatis* were killed in one hour" Can it be fairly said, then, that these were killed only after lengthy exposure, and does the word "only" apply at all to the one-hour results, when it is considered that there was no test made under the one hour? What is there to show that those of which there was no growth after one hour's exposure to the disinfectant had not been killed after ten minutes already?

Does it not look, then, as if Dr Klein had penned his letter without consulting either his notes or his report?

A word in conclusion Dr Klein, for whom perhaps nobody entertains a higher personal regard than myself, may rest assured that the designation, "a true disinfectant," is meant by me to apply only to such strengths of solutions of "Aminol" as can compete with those substances and their respective strengths to which Koch has accorded that appellation Nor need he to apprehend that anything has been or will ever be done by me intentionally committing him to what is not fully warranted by his actual results as recorded in his authorized published report

HUGO WOLLHEIM

101, Leadenhall Street, E C, January 2

THE point at issue between Mr Wollheim and myself is a very simple one, and needs no long explanation on behalf of Mr. Wollheim As you will see from the letter which you kindly printed in NATURE, *ante*, p 149, Mr Wollheim, without my authority, has sent round a leaflet with my name on it, accompanying bottles of "Aminol," stated to be "a true disinfectant"

1 On this leaflet my name is introduced in a somewhat misleading manner, for it quotes to a large extent from my reports on the lime and brine experiments on microbes without saying so, but leaving the reader to infer that these reports of mine refer to "Aminol"

2 Mr Wollheim never asked my permission or informed me of his intention of sending with each sample bottle of "Aminol" such a leaflet. It is unnecessary to say that had he asked me whether he could use my name on a wrapper of a patent medicine I should have emphatically answered *no* He has recently informed me that he has cancelled the leaflet

3 The samples of "Aminol" sent out were of the strength of 1 in 5000, the experiments in which I showed that "Aminol" possesses a certain disinfecting power were made with a strength of 1 in 600. This strength did not kill spores of anthrax in 12 hours; 1 in 6000 did not kill *Staphylococcus aureus* in 8 hours.

• A substance which, like the "Aminol" sent out (viz. 1 in 5000), cannot kill *Staphylococcus aureus* in 8 hours, and has practically no effect on spores of *Bacillus anthracis* cannot be considered "a true disinfectant."

To show that Mr. Wollheim had a very strange idea about the whole matter, one has only to compare the actual facts of the case, as regards "Aminol" of the strength of 1 in 5000, with the motto put on the leaflet and the inscription on the label of the samples For Mr Wollheim quotes Koch to the effect that no disinfectant can be called a true disinfectant that does not kill spores, and notwithstanding that I have shown that "Aminol" even of the strength of 1 in 600 cannot kill spores in 12 hours, yet Mr Wollheim advertises the "Aminol" of the strength of 1 in 5000 as "a true disinfectant" A true disinfectant kills spores after short exposure, a substance that requires many hours to do so cannot claim the name of a specific disinfectant Vinegar, dilute acids, alkalies, and a host of substances affect spores after exposure for many hours (8, 12, and 24 hours), yet no one would consider these substances as specific disinfectants

Again, a substance used in a certain strength (say 1 in 600) may have considerable disinfecting power on non-spore bearing microbes, with or without having any conspicuous action on spores The same substance more diluted (say 1 in 5000) may have retained such action only to a very insignificant degree Take for instance perchloride of mercury, while this substance is a powerful disinfectant when used in the strength of 1 in 500, 1 in 1000, even 1 in 2000, it has greatly less effect when used in more increased dilution

No one is justified in advertising perchloride of mercury of the strength of 1 in 100,000 as "a true disinfectant," knowing that 1 in 500 or 1 in 1000 only can be so called How much more does this hold good for a substance like "Aminol," which even in the strength of 1 in 600 does not kill the spores of anthrax in 12 hours, a period which for practical purposes of disinfection is out of the question

Super-abundant Rain

IN NATURE of November 10 the fact that "very nearly one-third" of the annual rainfall fell in one month at Nant-y-Glyn, in North Wales, is recorded as "remarkable"

But at Peshawar, on the north-west frontier of India, we received during last August a rainfall of 17 75 inches, the average local annual fall, calculated from the last fifteen years, being 13 51 inches

We therefore had very nearly sixteen months fall in one month, and by far the largest portion of this fell in ten days of the month

I need hardly add that the whole valley was flooded, and that we have since paid for our super-abundant rain in the form of very prevalent and fatal malarious fever

Peshawar, December 19, 1892

Earthquake Shocks.

THERE were two unmistakable shocks of earthquake on the afternoon of Tuesday, January 3, the first at 2h 15m 15s. G M T, and the second at 2h 17m I was sitting in a railway carriage at Severn Junction Station waiting for the Bristol passengers, when I felt a sensible upward movement of the seat (as if pushed from below) and saw the carriage sway The movement was from south to north (i e at right angles to the railway) This was repeated four times in about six seconds. At 2h. 17m. there were two more (less strong) shocks The carriage was placed in a siding, and there was no train at the station, and the air was calm and frosty Ice was said to have cracked near here at this time.

E J LOWE

Shirenewton Hall, Chepstow

A Brilliant Meteor

ON Wednesday, January 7, at about 6 35 p.m, I was fortunate enough to see a brilliant meteor descending a little north of Castor. My attention was drawn to it by the brilliant light it threw over the country. The head was a ball of dazzling white and the tail yellow, with red streaks It disappeared before reaching the earth, and I heard no report or rushing sound whatever

As the duration was only a few seconds the above are more impressions than observations.

Pirton, Herts, January 7

CHEMICAL SOCIETY'S MEMORIAL LECTURES

AT an extra meeting of the Chemical Society, held on December 13 last, this being the first anniversary of the death of Stas, a paper was read and discussed which had been prepared for the occasion by Prof J W Mallet, F R.S, of the University of Virginia, U S N A—himself a high authority on atomic weight determinations, and well known to chemists through his papers on the atomic weights of aluminium and gold, published by the Royal Society of London

The lecture marks a new departure in the work of the society Hitherto our learned societies have been in the habit of publishing more or less complete—it would probably be nearer the truth to say incomplete—obituary notices of their foreign members The Chemical Society has come to the conclusion, however, that inasmuch as its foreign members are always men of great distinction who, as a rule, have lived a considerable number of years after accomplishing their life work, it will be to the advantage of its fellows and of chemists generally, if the obituary notices of foreign members take the form of critical monographs of the subjects with which they have principally dealt

The anniversary of the death of the foreign member is obviously the most appropriate occasion for the delivery of such a lecture During the past year the society has lost two of its foreign members Hermann Kopp, noted as an historian, as well as on account of his very numerous exact determinations of atomic volumes and specific heats, and A W von Hofmann The life and work of the first mentioned will form the subject of a lecture to be delivered on February 20 next, by Prof Thorpe, the Treasurer of the Society, than whom no one is more qualified to undertake the task Prof Thorpe is not only a pupil of the deceased chemist, but has reverently followed in his footsteps—having very largely extended Kopp's observations on atomic volumes in an elaborate investigation, the importance of which was recognised by the Chemical Society in 1881 through the award to him of its first Longstaff medal

Von Hofmann, although originally a foreign member, became an ordinary member of the Chemical Society on coming to England as professor at the school in Oxford Street, long since merged in what is now known as the Royal College of Science, London Hofmann was never again regarded as a foreigner, he served the society both as foreign secretary and as president, filling one of the vice-chairs during the remainder of his life It is felt that owing to the special nature of his relations to the society and to english chemistry, it will be necessary to deal with his case in an exceptional manner, it is therefore hoped that in May next Lord Playfair—who was so intimately connected in his early days with chemical science and with the society—in the first place will picture the state of affairs chemical at and prior to the time of Hofmann's arrival in England Sir F Abel, Hofmann's first pupil and assistant, will follow with an account of Hofmann at the Royal College of Chemistry, calling to his aid for this purpose the remaining friends and pupils of Hofmann The coal-tar colour industry, which has now attained such important dimensions, it is well known, had its origin in the Oxford Street laboratory, and Dr Perkin—its parent—has consented to sketch the history of its development. In this manner it is hoped to impart considerable "local colour" to the Hofmann memorial lecture, thereby distinguishing it from the notice which is being prepared by the German biographers.

Passing now to Prof. Mallet's lecture on Stas, which is of considerable length, as it will occupy fully sixty pages in the Society's Journal. The biographical portion is brief, as a number of such sketches have already been published Stas was born at Louvain on August 21, 1813. He graduated as Doctor of Medicine His taste for chemical research was evidenced in 1835, when, together with a friend, he investigated in an attic of his father's house the crystalline substance phloridzin which they had extracted from the root bark of the apple tree He continued the study of this substance in Dumas' laboratory in Paris, and it is an interesting proof of the acumen of Berzelius that in his annual report on the progress of chemistry he referred to this first research made by Stas with praise, and a prediction of future eminence for the author

The starting-point of the long train of research with which his name will ever be associated was the redetermination of the atomic mass of carbon which Dumas and he together undertook, in order to explain the fact, noticed by Liebig and others, that the sum of the carbon and hydrogen found in hydrocarbons by the combustion process, as calculated from the carbon dioxide and water, not unfrequently exceeded the quantity of material analyzed As the result of this investigation, which was carried out with unprecedented care and the most elaborate precautions, the value hitherto accepted for carbon on the authority of Berzelius (76 432 $O = 100$) was considerably reduced (to 75 005) In 1840 Stas was appointed Professor in the École Royale Militaire at Brussels, he held this post for more than a quarter of a century, until an affection of the bronchial tubes and larynx obliged him to give up lecturing He then received an appointment in the Mint, but resigned this in 1872 on political grounds, and withdrew into private life He appears to have been a man of great independence of character

Apart from his atomic weight investigations Stas did much work of value in other departments His method of separating alkaloids from organic messes—no other name is applicable—which has been of such service in subsequent toxicological inquiries, was devised in 1850, in the course of the inquiry into the celebrated Bocarmé nicotine poisoning case He examined into the methods of hydrolysing fats for the purpose of a report on the chemical section of the London 1862 Exhibition In connection with the preparation of international standards he took an active part, along with Devile, in the inquiry into the properties of the platinum metals It is known also that he did important work for his Government in investigating alloys for use in the construction of artillery

Prof Mallet prefaces his account of Stas's special investigations by an historical survey of the fundamental ideas which have gradually led up to the question, What is the mass of an atom of a particular element? Even in and beyond the days of Cavendish and Priestley the fact that atmospheric air was found of constant or nearly constant composition was long a stumbling-block in the way of clear distinction between a homogeneous compound and a uniform mixture. To the labours of Van Helmont, Boyle, and Boerhave much credit is due for the gradual advance towards the doctrine of the conservation of matter The discoveries of Black and Cavendish brought it further into view, and it assumed its due importance and began to receive universal recognition with the constant appeal to the balance which Lavoisier made and taught others to make Next came a comparison of the quantities of different substances, at first chiefly the then known acids and bases, which would enter into combination with each other Proust, in the course of his controversy with Berthollet as to the fixedness of combining proportions, had observed that in certain cases it was true that in different compounds, consisting of the same constituents, for a fixed quantity of one constituent, the different quantities of another constituent bear to each other a simple multiple or sub-multiple relation To Dalton, however, belongs the honour of announcing the principle as a general one, and of basing upon it a true chemical atomic theory of the nature of matter. Berzelius,

in the early years of the present century, with apparatus in many respects inferior to that of the present day, and with scarcely any aid from chemical manufacturers in preparing pure materials and reagents, but with unsurpassed manipulative skill and the most honest criticism of his own work, produced the first fairly trustworthy list of numbers representing the proportions by weight in which the elements combine. Berzelius began work in this direction in 1807, his attention having been attracted by Richter's investigations, but soon afterwards he became acquainted with Dalton's new atomic theory of the nature of combination, and appears to have been impressed with its great importance, and at the same time with the need of more exact experimental data for its support and development. The wonderful accuracy of Berzelius's work generally is illustrated, as Prof. Mallet points out, by the fact that his number for oxygen, 16·021, becomes 15·894, almost exactly agreeing with the latest determinations of the present day, if the weighings of Dulong and Berzelius's three experiments on the synthesis of water be corrected for the buoyancy of the air. Since Berzelius many other chemists have worked in the same field, but his most worthy successor in such labours has undoubtedly been Stas. With greatly better resources in the way both of apparatus and material, with equal earnestness in seeking for the truth, with equal intelligence and skill he took up the task which became that of the largest part of his scientific life, and for a more limited list of elements than Berzelius had investigated, produced results of a degree of accuracy which it is high praise to say would have delighted no one more than Berzelius himself. He aimed at the determination with greater precision than any one before him had attained of the atomic weights of some ten or twelve of the elements. But by so determining these constants he endeavoured also to settle several general questions of fundamental importance in regard to matter as studied by the chemist.

Thus it has generally been assumed as true beyond dispute since the early part of the present century, that the mass of an atom of a given element is a constant quantity. This has, however, occasionally been doubted, and Stas himself considered the question as one requiring examination. His researches, however, lend no support to it. On this point Prof. Mallet expresses himself strongly in favour of the orthodox view.

Assuming that the atomic weights are immutable values, the question arises, Are they commensurable? This is the much-discussed hypothesis of Prout, the origin and development of which is very fully discussed by Prof. Mallet. A widespread feeling at one time undoubtedly existed among chemists that Prout's hypothesis, that the atomic weights of the other elements are integer multiples of that of hydrogen, if not true in its original form would ultimately prove to be so at least in a modified form. That Stas began his work under the influence of this feeling is clear from his own words:—

"Je le dis hautement lorsque j'ai entrepris mes recherches, j'avais une confiance presque absolue dans l'exactitude du principe de Prout."

But his experimental results clearly contradicted the hypothesis, and he satisfied himself that the atomic weights of the elements which he determined with such precision could not with truth be represented by integer multiples of the atomic weight of hydrogen, or the half or the fourth of this unit. In his own words:—

"Aussi longtemps que, pour l'établissement des lois qui régissent la matière on veut s'en tenir l'expérience, on doit considérer la loi de Prout comme une pure illusion. La simplicité de rapport de poids que présuppose l'hypothèse de Prout entre les masses qui interviennent dans l'action chimique, ne s'observe donc point dans l'expérience; elle n'existe point dans la réalité des choses."

The great majority of chemists—Prof. Mallet remarks—at the present day, are probably agreed in believing that the hypothesis of Prout has been shown by Stas to be untenable. But the fact that so many well determined atomic weights, referred to hydrogen as unity present numbers *nearly approaching integers*, is very striking and calls for further investigation. Stas himself is quoted as admitting this much. Prof. Dewar, in the course of the discussion after the paper was read, drew special attention to this question and gave several most striking instances of the nearer approach to whole numbers which resulted from a recalculation of the accepted values, using the lower value for oxygen (15·87) which so many recent researches tend to support, although on the other hand, of course, some of the values now near to whole numbers are considerably thrown out. Evidently there is ample opportunity for further experimental investigation of this all-important problem, and it is impossible—notwithstanding the extraordinary degree of accuracy attained by Stas—to formulate any final conclusion. The supreme interest attaching to the problem was clearly recognised by Stas himself, as the following words show:—

"Au point de vue de la philosophie naturelle, la portée de l'idée de Prout est immense. Les éléments des corps composés que nous considérons comme des corps simples en égard à leur immutabilité absolue pour nous, ne seraient eux-mêmes que des corps composés. Ces éléments, dont la découverte fait la gloire de Lavoisier et a immortalisé son nom peuvent être considérés ainsi comme dérivant de la condensation d'une matière unique: nous sommes naturellement conduits à l'unité de la matière, quoi qu'en realité nous constations sa pluralité, sa multiplicité."

This quotation is almost alone sufficient to show that Stas was a philosophical chemist of the highest order, and not a mere mechanical worker, as has sometimes been supposed; his unwearied attention to minutest details has undoubtedly served to completely overshadow the philosophical motives and aspirations by which he was guided.

Stas also endeavoured to obtain evidence with regard to the possible dissociation of the elements at high temperatures and to this end purified his materials with every imaginable precaution. The skill with which he carried out his operations is attested by the statement made by Mr. Crookes, the chairman at the reading of Prof. Mallet's paper, that he had seen in Stas's laboratory a large mass of potassium chloride, which Stas had been years in preparing, and in which he had failed to find a trace of sodium even spectroscopically—such an achievement appears almost inconceivable to the chemist. Stas, in fact, in the course of his work investigated the methods of analysis to be used with a degree of rigour, and discovered and applied refinements upon older methods of experiment with a degree of patience and skill, such as had never before been used in chemical investigation. Only those who are thoroughly conversant with such work can fully appreciate his labours; they probably will agree that owing to the multitude and diversity of the precautions to be taken, his work is the most difficult hitherto attempted, and that he stands unsurpassed among all who have undertaken the execution of exact physical measurements.

A lengthy section of Prof. Mallet's paper is devoted to the consideration of the objects to be aimed at and the methods to be pursued in future work. He advocates the repetition by competent hands of some one at least of Stas's fundamental results, calling attention to Stas's own emphatic expression of the wish that this should be done. It is also most important that no distinction should be made between rare and common elements, and that the atomic weights of all should be determined with the least possible delay and the highest attainable degree of accuracy. Certain of the elements particularly call

for a more searching and exact investigation of their atomic masses, *e g* elements such as tellurium, which occupies a position in the periodic system not in harmony with its atomic mass, and cobalt, which plainly occupies the intermediate position between iron and nickel, and therefore should be intermediate in atomic mass

In a number of cases the accepted value is based on the investigation of but a single interchange, the value for iron, for instance, being practically based on the results obtained on converting the metal into ferric oxide, and *vice-versâ*, and the relation of hydrogen to oxygen having been established by the reduction of cupric oxide. It is desirable that in such cases other and independent methods should be resorted to, *e g* that oxides of a number of metals other than copper should be reduced, with the object of detecting possible constant errors

It is eminently desirable that an attempt be made to directly determine the ratio of hydrogen to each of the halogens without in any way bringing in the atomic mass of oxygen Prof Mallet suggests various methods deserving of study Also it is very important that the metals of the yttrium and didymium groups should be further investigated Prof Mallet rightly terms the yttrium group the opprobrium of inorganic chemistry

Nearly all that has been written hitherto in regard to the periodic relationship among the elements has involved the use of roughly approximate values only, but it is time that the foundation be laid for a more minute and critical study of the periodic system of classification Anomalies in the classification as we now find it in our books, glimpses of more detailed relations than as yet clearly appear, tantalizing suggestiveness in so much of what is already before us, call for more precise determinations of the numbers we would discuss before we allow premature discussion to drift into mere fanciful speculation

In regard to the methods which it is desirable shall be pursued in the determination of atomic masses, Prof Mallet has much to say He discusses the selection of processes, the purity of materials, the very numerous directions in which vigilance must be exercised in order to avoid extraneous or accidental causes of error, the quantities of material to be used, the practical precautions to be observed so as to secure accuracy of manipulation and in weighing and measuring, the mode of stating and calculating results, finally calling attention to the advantage to be derived from the application of greater working force and ampler means than can be commanded by private individuals to the determination of atomic masses, with reference to this last point, during the discussion on the paper, the opinion was freely expressed that it was undesirable that such work should be carried out in organized public or semi-public laboratories The question is, no doubt, a difficult one to settle—such work demands a special temperament combined with genius of a high order and an infinite capacity for taking pains, qualities which must rarely occur united in a single individual Moreover, in order that the value of a result may be appraised, it is essential to overlook every detail involved in the determination Given the man, however, there can be no longer a doubt that every possible assistance he may require should be afforded him It is marvellous that men like Berzelius and Stas, working all but alone and unaided, should have achieved results of such magnitude and universal importance—the moral effect of their example is certainly not less important than are the actual results of their labour

The last section of Prof. Mallet's paper is devoted to the discussion of the form in which it is desirable finally to state the results. He here advocates the uniform substitution of the expression "atomic mass" for "atomic weight," on the ground that precision in language conduces to precision in thought—an aphorism far too commonly disregarded by chemists. We have now clear conceptions of atoms having constant mass for the same element, of determinable difference of mass in the case of different elements, the several masses and numbers of which regulate the composition of all known substances and the products resulting from interaction among them The atomic theory has advanced far beyond the condition of a mere working hypothesis on which chemists long stood with more or less uncertain feet, but even if this were not so, considering it, to use a common metaphor, only as a scaffold, there is no good reason, so long as we stand on it and work from it, that we should be careless about tying our scaffold-poles and nailing our planks

Lastly, Prof Mallet urges that all atomic masses shall be expressed in terms of the mass of the hydrogen atom taken as unity, objecting strongly to the change to $O = 16$ which several writers have recently advocated, the most objectionable argument put forward in favour of such change being, he thinks, that the numbers we use are expressive of *ratios* only—that any figures are allowable which correctly express combining ratios, and that there are no reasons for using one set of figures rather than another save mere arithmetical convenience This involves a grave error, as in adopting as unity the mass of a single atom of any particular element, preferably that one of which the mass is the smallest, we have reason to believe that we express the mass of all the others in terms of this as a really existent, definite, and constant quantity of matter It is, indeed, difficult to understand when the scientific necessity in so many cases of taking hydrogen as the unit is realized, how the change to $O = 16$ can be advocated except on the simple utilitarian plea that it is to the analyst's convenience

Prof Mallet's monograph is undoubtedly a most admirable exposition of the philosophical lessons to be learnt from the contemplation of Stas's labours

---

EXTINCT MONSTERS[1]

THE volume with this title treats of large animals It is clearly and simply written, without any pretence at being scientific, and is an excellent book for boys and unlearned people who are curious to be informed upon the subject of fossil animals It would have escaped criticism altogether but for emphatic words of praise in the preface, and one or two passages in which the author, with second-hand information, speaks authoritatively of predecessors who restored extinct types of life with the slender materials which were available forty years ago. The attraction of the volume and its novelty is a series of restorations of saurians and mammals drawn chiefly by Mr Smit These for the most part are based upon the restorations of skeletons made by Prof Marsh, whose discoveries have inspired Mr Smit's pencil as much as they have influenced the author's pen There is not much anatomy beneath the skins of the "Monsters," and they have an aspect as though cotton-wool had taken the place of muscle, or as though the drawings were models for the "Lowther Arcade" This, however, is of less importance than the answer given to the question, Are they reasonably faithful to nature? It does not seem to me that they can claim this merit, they are only reasonably faithful to Marsh. Prof Marsh draws an animal so as to give one type the maximum height to which the bones can be hoisted; while another is given the maximum length to which the remains can be extended. My own studies would not have led me to reconstruct one of the extinct reptiles upon the lines which are adopted in

[1] "Extinct Monsters." A popular account of some of the larger forms of ancient animal life. By Rev H N Hutchinson, B.A., F.G.S., with illustrations by J Smit and others. (London, Chapman and Hall, Ld, 1892.)

these restorations As an example of how a restoration should not be made, we may instance the figure of *Stegosaurus ungulatus* (p. 104), in which the management of the limbs is out of harmony with the evidences of the muscular structure of the tail, and the supra-vertebral crest The restoration of the Scelidosaurus from the Lias of England is unsatisfactory There is no better ground for giving a kangaroo-like position to that animal than there would be for drawing Teleosaurus in the same position. The mobility of the neck as drawn is astonishing

The restorations of mammals are happier The subjects diverge less from existing types And probably the most successful in the volume is the spirited restoration of *Sivatherium giganteum* from the Sivalic Hills, though the Glyptodon and Irish Deer are meritorious

In the text the author is generally content with telling the story of the history of science; but he sometimes strays into less safe matter. Thus an account is given of the eye of the Ichthyosaurus. And it is urged that the bony plates exercised a pressure on the eyeball, so as to make the eye more convex, and improve the definition of near objects The study of sclerotic defences does not support this interpretation; and in at least one generic division of the Ichthyosauria the sclerotic plates do not overlap at all, but join each other by their lateral sutural margins.

It is perhaps unfortunate that the author gives currency to nomenclature and classification of the terrestrial types of saurians which may not always prevail If the genera with a bird-like type of pelvis are terrestrial representatives of birds, and the genera with a reptilian type of pelvis are terrestrial wingless representatives of Pterodactyls, then it may not be an advantage to have the Dinosaurs treated as a homogeneous group, or the divisions adopted by Prof Marsh, or in the British Museum (Natural History), handed on to the unlearned as representing the best available classification On page 75, the author introduces a restored skeleton of Megalosaurus, which is attributed to Prof Marsh The skeleton certainly is not referable to Megalosaurus, which never has the pubic bones or the ilium constructed as in the figure The restoration has been previously used in Nicholson and Lydekker's "Palæontology," and in Dr Woodward's "Handbook to the Geological Department of the British Museum," but we do not remember any published authorization for the use of Prof Marsh's name as authority for confounding Megalosaurus with the allied American type

Another example of the same kind of interpretation occurs in dealing with Stegosaurus It is said to have been proved that bones to which the name Omosaurus has been applied really belong to Stegosaurus, and that an unnecessary name has been disposed of The ground on which this determination is made, not being stated, need not concern us now, but it is undesirable that a popular work, whose main merit is that it does not pretend to teach the facts of science, should appear to enunciate judgments on scientific problems. Having described the immense enlargement of the spinal cord in the sacral region of Stegosaurus, the author remarks — "So this anomalous monster had two sets of brains—one in its skull, and the other in the region of its haunches!—and the latter in directing the movements of the huge hind limbs and tail did a large part of the work" Remarks of this character are sure to be misunderstood, are out of place and incorrect

The author has read much, and shown an excellent capacity for quotation, but has not always succeeded in using the newest results He has conscientiously endeavoured to tell the story which is contained in his quotations, but beyond this he does not pretend, except

The four-horned extinct Mammal *Sivatherium giganteum* The animal on the left is Helladotherium.

in the occasional use of supposed scientific principles as a means of accounting for facts of animal structure He has dealt with a subject of great difficulty with commendable clearness, and will interest readers who would be unable to follow a more technical exposition of extinct types of life H G S

ENERGY AND VISION

THE interesting researches of Prof S P Langley on energy and vision have recently been published in the Memoirs of the American National Academy of Sciences From this we gather that he was led to investigate the question by the fact that it was not generally recognized how totally different effects may be produced by the same amount of energy in different parts of the spectrum Two series of experiments were necessary, the first to determine the amount of energy in each ray, the second to observe the corresponding visual effect. The energy was determined as heat by the use of the bolometer, the heat dispersed by a prism being very nearly proportionate to the energy

In the second series of experiments a beam of sunlight from a siderostat passes through a small hole in a darkened room and falls on a slit with a standard width of 0 1 mm It is then received on a collimating lens of 11 9 centimetres aperture and 755 centimetres focal length, after which it passes through a prism of about 60° refracting angle The spectrum thus formed is reflected and brought to a focus on a second slit of one millimetre aperture by a concave mirror, any particular colour being adjusted on the slit by a rotation of the prism This second slit is screened from all possible stray light by a dark curtain, and is used as a source of illumination for a series of numbers from a table of logarithms, which is attached to a sliding screen The greatest distance from the slit at which the figures could be distinctly read was then determined, and the law of inverse squares applied. For the brighter colours of the spectrum, the light entering the first slit was reduced by an adjustable photometer wheel

Actinometric measures were made during the progress of the photometric observations, and showed a solar radiation of 1 5 calories per square centimetre per minute, this naturally being an essential unit

The energy necessary to give the bare impression of luminosity in different parts of the spectrum, expressed in terms of horse-power, was found to be roughly as follows, the *minimum visibile* being defined as the feeblest light which is observed to vanish and reappear when silently occulted and restored without the knowledge of the observer —

	Horse-power
Violet (λ 400)	0 000000 000000 00018000
Green (λ 550)	0 000000 000000 00000075
Scarlet (λ 650)	0 000000 000000 00017000
Crimson (λ 750)	0 000000 000000 34000000

These values were derived from observations made by a single observer, Mr F W Very, and are, of course, subject to a large percentage of error

The general results of the investigation may be best summarized in Prof Langley's own words —

"The time required for the distinct perception of an excessively faint light is about one-half second A relatively very long time is, however, needed for the recovery of sensitiveness after exposure to a bright light, and the time demanded for this restoration of complete visual power appears to be greatest when the light to be perceived is of a violet colour. The amount of energy required to make us *see* varies enormously according to the colour of the light in question. It varies considerably between eyes which may ordinarily be called normal ones, but an average from those of four persons gives the following proportionate result for seven points in the normal spectrum, whose wave-lengths correspond approximately with those of the ordinary colour divisions, where unity is the amount of energy required to make us see light in the extreme red of the spectrum near A, and where the six preceding wave-lengths given correspond approximately to the six colours, violet, blue, green, yellow, orange, red

Colour	Violet	Blue	Green	Yellow	Orange	Red	Crimson
Wave length	400	470	530	580	600	650	750
Luminosity	1600	62 000	100 000	28 000	14 000	1200	1

It appears from this that the same amount of energy may produce at least 100,000 times the visual effect in one colour of the spectrum that it does in another

If now it be inquired what the actual value of unity is in ordinary measure, we are able to give this also with a fair approximation, and to say that the *vis-viva* of the waves whose length is 7500 (tenth metres) being arrested by the ordinary retina, represents work done in giving rise to the sensation of the deepest red light of about 0 001 of an erg in one-half second

NOTES

THE Prince of Wales has consented to become Chairman of the Committee for the memorial of the late Sir Richard Owen, and to preside at a meeting to further the object, which will be held in the rooms of the Royal Society, Burlington House, on Saturday, the 21st inst, at half-past eleven o'clock Admission will be by tickets, which may be obtained from Mr Percy Sladen, Linnean Society, Burlington House, W (who is acting as secretary to the Committee), or from Mr H Rix, assistant secretary of the Royal Society

THE annual general meeting of the Royal Meteorological Society will be held at 25, Gre at George-street, Westminster, on Wednesday, the 18th instant, at 7 15 p m, when the Report of the Council will be read, the election of officers and council for the ensuing year will take place, and the President (Dr C Theodore Williams) will deliver an address on "The High Altitudes of Colorado and their Climates," which will be illus trated by a number of lantern slides This meeting will be preceded by an ordinary meeting, which will begin at 7 p m

THE general meeting of the Association for the Improvement of Geometrical Teaching is to be held at University College, Gower Street, W C, on Saturday, January 14, the Rev C Taylor in the chair At the morning sitting (11 a m) the report of the Council will be read, the new officers will be elected, and several candidates will be proposed for election as members of the Association After the conclusion of the formal business Mis Bryant will give "A Model Lesson on Geometry, as a Basis for Discussion" After an adjournment for luncheon at 1 p m members will re-assemble (2 p m.) to hear papers by Mr G. Heppel on "The Use of History in Teaching Mathematics," and Mr F E Marshall on "The Teaching of Elementary Arithmetic" Members who wish to have any special matter brought forward at the general meeting, but who are unable to attend, are requested to communicate with one of the Honorary Secretaries. All interested in the objects of the Association are invited to attend

DR. LUDWIG BECKER has been appointed to the chair of astronomy at the University of Glasgow.

THE Comet Medal of the Astronomical Society of the Pacific Coast has been awarded to Mr Edwin Holmes, of London, for his discovery of a new comet on November 6.

ON Tuesday next (January 17) Prof. Victor Horsley, F.R.S., will begin a course of ten lectures, at the Royal Institution, on "The Functions of the Cerebellum and the Elementary Prin-

ciples of Psycho-Physiology" The Friday evening meeting will begin on January 20, when Prof Dewar, F R S, will give a discourse on "Liquid Atmospheric Air"

THE severe frost which set in just before Christmas was succeeded by a rapid rise of temperature in Scotland on Friday, but in England the thermometer did not rise much above the freezing point until about twenty-four hours later On the 5th and 6th instant the thermometer fell below 10° in many parts of Great Britain, and snow was falling in Scotland, which afterwards spread to many parts of England The absolute shade minima recorded were—2° at Braemar, and 2° at Fort Augustus, in the north of Scotland The distribution of pressure was unusually high over Scandinavia and northern Europe (inadvertently referred to in our issue last week as over these islands) having reached about 31 3 inches in Central Russia on the 4th, while areas of low pressure lay over the Gulf of Genoa and the south-west of Ireland The latter depression gradually extended eastwards, causing strong easterly gales on the Irish coasts, while the anticyclone over Europe gradually gave way, the barometer at Haparanda on Monday being 1 5 inch lower than a few days previously By Sunday all stations reported temperatures above the freezing point, while in the south west of Ireland the maxima reached 47° and in the south of France even 63° These changes were accompanied by rain in most parts of the country, which added materially to the rapidity of the thaw Bright aurora was seen on Monday night in Scotland and Ireland On Tuesday an anticyclone from the north-westward was spreading over our islands, with finer weather and lower temperatures generally, frost occurring in the north of Scotland and the central parts of England. The *Weekly Weather Report* of the 7th instant showed that the temperature in the eastern and midland parts of England was 12° to 13° below the average for the week, at several of the inland stations in England the daily maxima were below 32° through the whole period

AN enlightened Bengali, Babu Govind Chandra Laha, has contributed fifteen thousand rupees towards the expenses of the proposed snake laboratory at Calcutta. We may expect, therefore, that the institution will soon be in full working order According to the *Pioneer Mail*, two main lines of research will be followed in the laboratory So-called cures for snake bites will be tested under strictly scientific conditions, and the properties of the snake poison as such will be investigated The laboratory will be the only institution of its kind in the world, and the Committee of the Calcutta Zoological Gardens, who have taken the matter in hand, expect that it will be largely resorted to by the scientific inquirers who visit India during cold weather In accordance with the practice of scientific laboratories in Europe, a charge will be made for the use of the tables and instruments at a rate sufficient to cover working expenses Work done on behalf of the Government will also be charged for according to a regular scale.

THE members and friends of the Society for the Study of Inebriety met on Tuesday to congratulate Dr. Severin Wielobycki on having completed one hundred years of life

PROF BAIN contributes to the new number of *Mind* an interesting sketch of the career of the late Prof G C Robertson, with whose name *Mind* will always be intimately associated. Prof. Bain includes in his article the admirable notice of Robertson written by Mr Leslie Stephen for the *Spectator*.

WE are glad to note the publication of a fifth edition, revised and augmented, of the Official Guide to the North Gallery at the Royal Gardens, Kew. It includes a short and interesting biographical notice of Miss North. A map is given to convey some idea of the extent to which her collection illustrates the vegetation of the temperate and tropical regions of the world.

A NEW edition of the list of members of the Institution of Civil Engineers, corrected to the 2nd inst, the seventy-fifth anniversary of its establishment, shows that the aggregate number of all classes is 6341, an increase during the past year at the rate of 3½ per cent

A PSYCHOLOGICAL laboratory has been established at Yale College, where Prof Ladd has for some years been lecturing on physiological psychology *Science* gives an interesting account of the new institution, which has been placed under the charge of Dr E W Scripture, a pupil of Wundt The laboratory consists of fifteen rooms, three of which, including an "isolated" room, are given over entirely to research The isolated room is a small room built inside of another room, four springs of rubber and felt are the only points in which it comes in contact with the outer walls The space between the walls is filled with sawdust as in an ice-box The room is thus proof against sound and light, and, according to *Science*, affords an opportunity of making more accurate experiments on the mental condition than any yet attempted

STUDENTS of ethnography will be interested to hear that Dr N B Emerson, of Honolulu, is preparing a full account of the Polynesian canoe In a communication printed in the new number of the Journal of the Polynesian Society he points out that the various migrations of the ancient Polynesians and their progenitors, from whatever source derived, must have been accomplished in canoes or other craft, and that the *waa*, the *pahi*, &c, of to-day, however modified they may be under the operation of modern arts and appliances, are the lineal descendants of the sea-going craft in which the early ancestors of the Polynesians made their voyages generations ago He holds, therefore, that a comparative study of the canoes cannot fail to shed light on the problems of Polynesian migrations and relationships

AN interesting little paper on the destruction of wild birds' eggs, and egg-collecting, is contributed to the new number of the *Annals of Scottish Natural History*, by Col W H M Duthie Collectors who require to be specially dealt with he groups in three classes—the aimless, the greedy, and the mercenary In contrast with these is "the true collector," whom Col Duthie defines as "a naturalist, acquainting himself with birds, their habits, flight, migration, language, and breeding haunts, his egg collecting being only one of the means of acquiring this knowledge" The true collector should collect for himself, and should never receive an egg into his cabinet unless authenticated by an individual in whom he can implicitly trust If all collectors were of this type, egg-dealers would cease to exist, and with them would disappear the tribe of hangers-on whom they maintain

A GOOD study of the form of eggs has been recently made by Dr Nicolsky of St Petersburg He constructs an abstract formula, by which different eggs can be compared without regard to absolute dimensions. Calling the longer axis 1000, he obtains a figure representing the ratio of the longest transverse axis to it, and another, that of the distance of the obtuse end from the "centre," or point where the longer axis cuts the plane of the equator, then forms a fraction with these two figures, and takes it as the formula of the egg Various explanations have been offered for the different forms of eggs Dr Nicolsky traces all to gravity He considers that every egg not yet coated with a solid shell departs from the spherical form and elongates, simply because of pressure on it by the walls of the ovary. In birds which keep a vertical position when at rest (such as the falcon and owl) the soft egg becomes short through the bird's weight acting against the ovarian pressure. In birds which, like the grebe, are nearly always swimming, the egg lengthens, because the body weight acts in the same direction as the ovarian compression Lastly, eggs become

pyriform (more pointed at one end than the other) in birds which, like the guillemot, often change their position, sometimes swimming and diving, sometimes perching on rocks, &c. An examination of all the eggs in the zoological collection of the St Petersburg University fully bore out these views Dr Nicolsky thinks it would be useful to test the theory by experimentation, birds being kept in a vertical or horizontal position at the laying time

FOR twelve years (1878 to 1890) M P Plantamour made careful observations of the displacements shown by two spirit levels (one north-south, the other east west), in the cellar of his house at Sécheron The instruments were transferred to the Geneva Observatory, and the work resumed by M Pidoux in April 1891 (after six months' interruption) M Plantamour found that the mean air temperature had a preponderating influence in the oscillations observed, while some other factors of obscure nature were involved The first year's data at Geneva (*Arch de Sci*) reveal an annual oscillation of the ground of the Observatory about an axis directed north east and south west, such that the south-east part sinks in summer and rises in winter The east side went down till July 16, then rose gradually till the end of December (29), thereafter sinking again The extremes were $-4'' 73$ and $+4'' 85$ (an amplitude of $9'' 58$) The variations of the south side were similar, but the amplitude somewhat greater The north-south level showed some quite abnormal variations in the autumn of 1891, to which, however, the author does not attach great importance

AN interesting contribution to our knowledge of the adaptation of structure to function in the human body is afforded in an investigation by Signor Minervini (of the Naples Society of Naturalists) of the blood-vessels of the skin in different parts Portions of skin were prepared so as to show the exact structure of the chief arteries in them The results are as follows — (1) The artery-walls of the skin in men are generally thicker than those of other organs (2) This greater thickness is due generally, and during most of life, to thickening of the middle layer, but in childhood the outer, and in advanced years the innermost, layer is most developed (3) The artery walls in the hollow of the hand, the finger-tips, and the sole, are, other things equal, thicker than those in the back of the hand, the forehead, the arm, &c. This greater thickness is due chiefly to a greater development of the middle layer, and in all ages of life The arteries in the hollow of the hand in the case of occupations involving hard manual labour show a greater increase of thickness than in the case of those with little or no such work In these cases all three layers of the artery are thickened, but the middle layer most (4) In women all the chief arteries of the hollow of the hand and of the back of the hand are somewhat less thick than in men The difference is not great, but occurs at all ages.

IN a paper on the Santa Isabel Nitrate Works, Toca Chile, read lately before the Scottish Institution of Engineers and Shipbuilders, and now printed in the Institution's Transactions, Mr. G. M Hunter has something to say regarding the origin of "caliche," as nitrate of soda is called in its native state Some contend that "caliche" is a marine deposit, others that it is an animal deposit, while others say it is a vegetable deposit. Mr Hunter holds the first of these views. The coast of Chile has several times been disturbed and upheaved by volcanic agency, and he suggests that a large tract of sea was enclosed and heaved up to the present height of the nitrate region, and there formed an inland sea, which, after a lapse of time under a tropical sun, evaporated, leaving the salts to percolate and form the beds of nitrate From the formation of the ground, showing depressions and ravines leading to the sea, it is evident that immense volumes of water at some remote period have passed through them In proof of this, Mr Hunter points out that no "caliche" is ever found in such places, the accepted opinion being that there has been a "wash out," as it is called During a later period than that of the formation of the "caliche" great floods passed over the plains, as is shown by the deep tracks of rivers, and the smooth washed appearance of the surface Such periodical floods are common in tropical, rainless regions, and would not call for special remark, but from the fact that wherever these river tracks or washed surface appear no "caliche" can be found. This is so well known that even the workmen never attempt to search for it in such places The only surface indication for the presence of "caliche" is rising ground covered with small black stones. The "caliche" in its native state is white, very compact and amorphous, not unlike rock salt, but when rich in iodine it assumes various colours, according to the composition and quality of the iodine it contains. For example, at times it contains masses of bright yellow, red, or blue, and again wholly composed of a dull black colour, in which state it requires an expert to distinguish it from *costra* or rock

MR. E LOMMEL claims to have found a simple explanation of the Hall effect A simple train of reasoning shows, he says, that the equipotential lines perpendicular to the lines of flow in a plate are also the lines of force due to the current If iron filings are strewn upon the plate they will arrange themselves along the equipotential lines if the current be strong enough. On bringing the plate into a magnetic field these lines of force change their position Hence the lines of flow, necessarily orthogonal to the lines of force, will also change in form and position

ACCORDING to Dr J Bohm, the statement that *Phytophthora infestans*, the fungus which causes the potatoe diseases, hibernates in the tubers, is incorrect, nothing whatever being known about its mode of hibernation He further states that the infection of the potatoes never takes place in the soil through the uninjured skin, but is always brought about through injury to the tubers by insects or snails In potatoe heaps sound tubers can never be infected by their diseased neighbours An infected potatoe either does not germinate at all or produces a healthy plant

IN examining milk which is suspected to contain the tubercle bacillus it is usual to subject a sample of the milk to the action of a centrifugal machine after separating the fat One method of working is described by Ilkewitsch (*Munchener med Wochenschr* 1892) The casein in 20 c.c of milk is coagulated with citric acid, and, after filtering, the residue is dissolved in a solution of sodium phosphate. The butter-fat is separated by shaking with 6 c.c. of an aqueous ether solution, and acetic acid is then added until the liquid is on the point of coagulating It is then placed in a copper tube tapering at the bottom, and this tube is inserted in the centrifugal machine and turned at the rate of 3600 revolutions per minute for fifteen minutes. The bacilli collect at the narrow end of the tube together with other sediment and dirt The liquid is poured off, and the sediment examined microscopically Thörner (*Chem. Ztg* 1892, pp. 791–2) gives another method, which is as follows :—20 c.c. of the suspected milk are mixed with 1 c c. of 50 per cent. potash solution, and heated in a bath of boiling water until the fat is saponified, when the solution turns yellowish brown. By this treatment the casein and albumen become soluble in acid Twenty cubic centimetres of acetic acid are added, the solution shaken, heated on water-bath for three minutes, transferred to a strong glass tube, and turned in the centrifugal machine for ten minutes. The liquid is poured off, and the sediment is washed by shaking with 30 c.c. hot water, and again turned in the centrifugal machine. The water is poured off, and the sediment placed upon cover-glasses, which are treated in the ordinary way,

staining with hot Neelsen's solution, decolourizing in 25 p c sulphuric acid, and finally staining in methylene blue, instead of washing the cover-glasses in sulphuric acid Thörner simply uses a solution of methylene blue containing sulphuric acid

A METHOD of producing an intense monochromatic light is described by Dr Du Bois (*Zeitschr. fur Instr* p 165) It differs from the usual processes in the form in which the sodium is introduced into the flame A mixture of sodium bromide and bicarbonate is made cohesive by adraganth and moulded into sticks 4 mm. in diameter and 12 to 15 cm long These are kept in the flame of a Linnemann burner by means of a rack and pinion motion Their conductivity being very low, they are only vaporized at the extreme end. The latter must be covered to avoid a continuous spectrum At the greatest intensity, two or three centimetres of the substance are consumed per minute The spectrum exhibits, besides the enormously preponderating D lines, a air of lines in the green, and a fainter pair in the red

FROM the ages of persons who have died in France during the last 32 years, M Turquan computes the average life there to have been about 38 years for women, 36 for men, and 37 years for both sexes together (*Rev Sci*) But this is now exceeded, and the average is over 40 years, a result, partly, of more attention to hygiene, partly of a diminished birth-rate From a map showing the distribution of the average life, one finds the average very low in Finistère and Brittany (28 years 11 months in the former) in the Nord, the Pyrénées Orientales, &c, and especially in Corsica (28 years 1 month) In Finistère and Corsica one finds least hygiene and most children, but not the highest mortality of children. In some parts of Normandy, with a high infantile mortality, the mean life is yet very long Thus it is about 48 years in Eure, 47 in Orne and Calvados, &c. The difference between the average life of men and women rises to 4 years (excess in case of women) in the north-west, and diminishes as you come towards the Mediterranean, and in Basses Alpes and Gard (in the south-east) man lives longer than woman by about a year and a half. In Normandy and Brittany there are most widows, and woman appears to have a greater vitality

IT is now many years since electric currents were proved to exist in plants In the study of these currents, an important step in advance was taken when Prof Burdon Sanderson proved their existence in *uninjured* parts of living plants (it was usual before to apply electrodes, often polarizable, to cut parts) As to their cause, certain experiments made by Kunkel, some time ago, led him to think it was in the purely mechanical process of water-motion, set up on application of the moist electrode The subject has been recently investigated by Herr Haake, who pronounces against this view He used Du Bois Reymond's clay electrodes, with some woollen fibres projecting at the ends, and he enclosed the leaves in a tube in which they were guarded from air-draughts and kept moist. Arrangements were also made for various operations, such as varying transpiration, admitting hydrogen, removing oxygen, &c (for details see *Flora*, p. 455, of this year) Herr Haake's results are briefly these — 1. It is unquestionable that changes of matter of various kinds are concerned in the production of the electric currents, especially oxygen respiration, and carbonic-acid assimilation 2 Water-movements may possibly share in their production, but certainly their share is but a small one

THE *Isvestia* of the East Siberian Geographical Society (vol. xxiii, 3) contains an account of M Obrutcheff's further researches in the Olekma and Vitim highlands. In the north-eastern, formerly quite unknown part of this region, the author found a further continuation of the "Patom plateau"—that is, a swelling from 3500 to 4000 feet high, devoid of tree vegetation, with ridges and mountains rising over it to heights of from 5000 to 5600 feet They consist of granite and crystalline schists, probably of Laurentian age, covered with younger, probably Huronian, gneisses and schists The other parts of the highlands consist of Cambrian and Lower Silurian deposits, while Upper Silurian limestones and Devonian Red sandstones are only met with in the valley of the Lena We thus have a further confirmation of the hypothesis, according to which the great plateau of north eastern Asia is a remnant of an old continent which has not been submerged since the Devonian epoch Further traces of mighty glaciation have been found in the south east part of the region As to the gold bearing deposits, they are pre-glacial in the south, and post-glacial or recent in the north The high terraces in the valleys are indicative of a considerable post-pliocene accumulation of alluvial deposits, and of a subsequent denudation on a great scale

MESSRS MACMILLAN AND CO announce that a new edition of Sir Archibald Geikie's "Text-book of Geology" is in the press, and will appear shortly

THE third and fourth volumes (completing the work) of Mr H C Burdett's "Hospitals and Asylums of the World" will be published by Messrs J and A Churchill about the end of this month Vol iii deals with the history and administration of hospitals in all countries throughout the world Vol iv relates to hospital construction, and contains a bibliography and portfolio of plans

MESSRS R SUTTON AND CO have published a second edition of Mr J E Gore's "Scenery of the Heavens," with stellar photographs and various drawings. Mr W F Denning contributes to the volume a chapter on fireballs, shooting stars, and meteors.

THE second annual issue of "The Year-Book of Science," edited by Prof Bonney, F R S, is now in a forward state of preparation, and will be shortly published by Messrs Cassell and Company

MESSRS DULAU AND CO have published "Annals of British Geology, 1891," by J F Blake This is the second issue, and geologists will be unanimously of opinion that it is a decided improvement upon the first It contains a digest of the books and papers published during the year, with occasional notes

LECTURES on the ear will be delivered in Gresham College, Basinghall Street, E C, on January 17, 18, 19, and 20, at 6 o'clock, by Dr E Symes Thompson

IN Mr R Assheton's letter (NATURE, vol xlvii p 176) the sentence beginning line 31 of the second column should have read thus.—"But it is more metazoic—if I may use such a word—to call the whole animal resulting from the segmentation of the fertilized ovum, the sexually produced generation."

TWO interesting new compounds are described by Prof Anschutz, of Bonn, in the current number of the *Berichte* They are well-crystallized compounds of the lactides derived from salicylic acid and the next higher (cresotinic) acid with chloroform, which latter substance is so loosely united with the lactide that warming to the temperature of boiling water is amply sufficient to dissociate them Hence the compounds may be employed for obtaining perfectly pure chloroform, and for preserving chloroform in a solid form in which it is not prone to decomposition The lactide of salicylic acid has long been supposed to be formed when the acid is treated with oxychloride of phosphorus, Prof Anschütz, however, shows that the product of this reaction contains many other substances in addition, but by working under special conditions he has succeeded in

isolating pure salicylide Salicylic acid is dissolved in an indifferent solvent, preferably toluene or xylene, before the addition of the phosphorus oxychloride The product of the reaction is washed first with soda and afterwards with water Owing to the property, discovered by Prof Anschutz during the course of the work, which salicylide possesses of combining with chloroform, it may be extracted from the white solid product, after drying, by means of chloroform, the compound being deposited from the chloroform solution in large colourless transparent crystals belonging to the tetragonal system The compound possesses the composition C_6H_4 CO O $2CHCl_3$ The chloroform readily escapes upon warming, in very much the same manner as the water of crystallization contained in many crystallized salts The free salicylide remaining is a solid substance melting at 261° As regards its molecular constitution it is shown, by the amount of lowering of the melting-point of phenol employed as a solvent, to contain four of the salicylic radicles C_6H_4 CO O, and is probably a closed ring compound In a precisely similar manner phosphorus oxychloride reacts with the three cresotinic acids, the acids next higher than salicylic, with formation among other substances of lactides, which may be isolated in the same way in the form of their chloroform compounds, CH_3 C_6H_3 CO O $2CHCl_3$ Ortho-cresotinic acid lends itself best to this reaction The pure lactides are readily obtained from the chloroform compounds by warming to 100°, pure chloroform being gently evolved

THE two substances above described, salicylide chloroform and the corresponding compound derived from ortho-cresotinic acid, are admirably adapted for the preparation of pure chloroform, on account of their large content of the latter substance, salicylide-choloroform containing 33 24 per cent and the cresotinic compound 30 8 per cent of its weight Moreover, in closed vessels they may be preserved any length of time, when exposed to the open air salicylide chloroform slowly loses its chloroform, but the cresotinic compound is well nigh stable, even under these conditions The same quantity of the free lactide may be used over and over again without decomposition, it being only necessary, in order to re-form the chloroform compound, to allow it to remain in contact with the chloroform to be purified for twenty-four hours at the ordinary temperature None of the usual impurities in chloroform crystallize along with the compound, so that a perfect separation is effected Again, it is well known that pure chloroform decomposes more or less on keeping, this loss may be avoided by storing it in the form of the lactide, and regenerating it when required by the application of a gentle heat, with the certainty of obtaining it perfectly pure

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus rhesus* ♀) from India, presented by Mr W Stutely, two Barbary Mice (*Mus barbarus*) from North Africa, presented by Lord Lilford, four Bearded Titmice (*Panurus biarmicus*), European, four Ani (*Crotophaga ani*) from South America; six Hog-nosed Snakes (*Heterodon platyrhinos*), a Striped Snake (*Tropidonotus sirtalis*); a —— Snake (*Pitnophis* ——), from North America, purchased.

OUR ASTRONOMICAL COLUMN

THE MOTION OF NOVA AURIGÆ —Prof. W W. Campbell, of the Lick Observatory, has communicated further results relating to Nova Aurigæ to the December number of *Astronomy and Astrophysics* He is now perfectly convinced that the variation in the velocity previously suspected is real, and probably due to orbital motion The values given below have been calculated on the assumption that the brightest line in the spectrum of the Nova, since the reappearance in August, is really the chief nebula line The bright lines were displaced towards the violet, indicating approach, whereas in February and March last they were displaced towards the red

Date 1892	λ	Velocity of approach Miles per sec
Aug 20	5003 6	128
21	3 7	125
22	3 7	125
23	3 1	147
30	2 4	173
Sep 3	2 4	173
4	1 9	192
6	2 1	184
7	1 9	192
15	2 2	180
22	2 5	169
Oct 12	3 6	128
19	3 8	121
Nov 2	4 4	99
3	4 7	87

In the same journal Mr Sidgreaves points out that the new lines cannot simply be revivals of those of February, and, further, that on account of the great difference of velocities and the reversed direction, they cannot be supposed to belong to the bright-line component of February Neither is it likely that the dark-line component has become a planetary nebula, and the probability of three bodies rushing together being very small, Father Sidgreaves believes the new results to strengthen the view that the compound character of the spectrum was produced by local disturbances of a single star

ASTRONOMICAL DISCOVERIES IN 1892 —In the *Observatory* for January Mr Denning gives an excellent summary of the astronomical discoveries of 1892, a year which was very remarkable for the special attention given to the science by the press and the public In chronological order the principal events were as follows —

January 20 —Minor planet (324) discovered by photography by Max Wolf at Heidelberg (Altogether 27 were discovered during the year by various observers)

January 23-30 —Discovery of Nova Aurigæ by Dr Anderson

February 11 —The great sun spot, extending over 150,000 miles of longitude, reached the sun's central meridian This was followed by remarkable magnetic disturbances and displays of aurora

March 6 —Comet discovered by Lewis Swift

March 18 —Comet discovered by Denning at Bristol On this day also, Dr Spitaler, of Vienna, re-detected the periodical comet of Pons (1819) and Winnecke (1858)

August 6 —Opposition of Mars Mr Denning writes. "Practically our knowledge stands where it stood before The results are not sufficiently discordant to settle disputed points."

August 27 —A new comet discovered by Brooks, of Geneva, N Y.

September 9 —Prof Barnard's memorable discovery of the fifth satellite of Jupiter

October 12 —Comet discovered by photography by Prof Barnard

November 6 —Bright comet discovered in Andromeda by Mr Edwin Holmes, London

November 20 —A faint comet discovered by Brooks

November 23 —Brilliant shower of shooting stars observed in Canada and the United States The shower was evidently that of the Andromedes connected with Biela's comet.

COMET HOLMES —Mr Lewis Boss finds for this comet a period of 6 914 years, and concludes that no very close approach to Jupiter can have taken place in recent years; the eccentricity, however, is so small that important perturbations by Jupiter may have occurred He further states that "the recent remarkable decrease in brightness of the comet seems to do away with the necessity of supposing that it has been recently made a member of the solar system. This decrease also renders it reasonably certain that the comet must have been subjected to some extraordinary disturbance of its internal economy, by the application of forces from without or within, with the result of giving to it that which was really an unaccustomed and temporary size and brightness" (*Astronomical Journal*, No 283). According to Mr. Lockyer's views, such increase of brightness would be produced by the comet colliding with another meteor

swarm lying in its track, and it is quite possible that the brightening of the comet at the time of the discovery was very sudden, thus explaining why the comet was not detected earlier

The Rev E M Searle (*Astronomical Journal*, No 283) has deduced a period fifteen days shorter than that of Mr Boss

M Schulhof, of Paris, finds a period of 6 909 years He also points out that among the known periodic comets that of De Vico shows the greatest orbital similarity to Holmes's comet, and he considers that they may possibly have a common origin

Mr Roberts, of the Nautical Almanac Office, accepting as real the supposed impression of the comet obtained by Mr Schorling in a photograph of the region taken on October 18, found a period of fifteen years, but the general agreement of the latest computations seems to indicate that the image in question could not be that of the comet

The comet is now so dim that it is not considered necessary to continue the ephemeris

EPHEMERIS OF COMET BROOKS (November 20, 1892) —The following ephemeris of Comet Brooks (Berlin, midnight) is given in *Ast Nach*, No 3140, by Kreutz —

Date	R A	Decl (app)	Log r	Log Δ
	h m s	° ′

THE METEOR SHOWER OF NOVEMBER 23, 1892 —Further observations of this fine display of shooting stars are recorded in *Astronomical Journal*, No 283 Prof J K. Rees counted 165 meteors in half an hour, and noted some as bright as Mars, all of them were very swift The Rev J G Hagen estimated that one observer, with a clear view to the west would have seen 250 meteors in half an hour, and notes that some were as bright as Jupiter Mr Sawyer estimated the maximum frequency as about 300 per hour, and, strangely enough, describes them as "slow-moving, generally quite bright, although none were observed as bright as the planets Mars and Jupiter" Both Prof Rees and Mr Sawyer note that the meteors appeared in clusters, four or five falling almost at the same instant, while for a few minutes none were seen The radiant was near γ Andromedæ, and there is little doubt that the shower was that due to Biela's comet

GEOGRAPHICAL NOTES

IN M Dybowski's journey from the Mobangi to the Shari, as described at a recent meeting of the Paris Geographical Society, he encountered one of the most systematically cannibal tribes which has yet been described This tribe, known as the Bonjos, have only one object of purchase—slaves to be eaten They refuse to sell food or any other products of their country for anything else, and the surrounding tribes capture and export canoe-loads of slaves for this purpose The French expedition experienced great difficulty in obtaining food amongst a people who had no desire for ordinary articles of trade.

THE boundaries of the republics of South and Central America are certainly the least definite lines on the political map of the world so far as civilized lands are concerned. The question of delimitation is never at rest Dr. H. Polakowsky gives in the last number of *Petermann's Mitteilungen* a brief account of the negotiations and surveys relating to the frontier of Costa Rica and Nicaragua from 1858 to 1890 The difficulty in this case lies in the fact that the mouth of the San Juan river, a certain point of which was fixed on in 1858 as the coast frontier, is continually changing, and a breakwater belonging to the harbour and canal entrance of Greytown, in Nicaragua, now stands in what was formerly the territory of Costa Rica On the Pacific coast years of diplomacy were required to fix the centre of Salinas Bay, but it is satisfactory to know that permanent boundary stones have now been erected at both ends of the line

MR. COLES delivered his second lecture to young people under the auspices of the Royal Geographical Society, on Friday evening, when a large audience of both young and old enjoyed his spirited descriptions of Iceland and British Columbia, illuminated by many anecdotes of personal adventure

THE defective condition of the charts, even of the coast of Europe, was strikingly brought out by the recent court martial on the stranding of H M S *Howe* in Ferrol Channel The chart used on board was drawn from soundings made about a hundred years ago, with a few subsequent corrections, which failed altogether to indicate the rock on which the *Howe* struck. The Spanish authorities are reported to have refused permission for the new chart surveyed by the officers of the Channel Squadron to be published, and meanwhile the Hydrographic Office has cancelled the old chart

A NEW SEISMOGRAPH

BEFORE speaking of this memoir, let me enter a protest against the method of publishing these "Annali" in such a way as to convey the impression that the papers composing it were written three years before their actual date All readers are warned that when the volume is bound up, and the paper covers are removed, they must post date the papers by three years

The seismograph described in the present paper is intended for stations of the second class The objects in view in its construction were amplification of the record in a pendulum seismograph, and improvement of the warning apparatus in the form of a style seismoscope of the Milne type which the author finds frequently fails

The amplifying lever is composed of fine placfont tubes arranged girder-like in the form of a short hollow triangular prism, surmounted by an acute triangular pyramid, which points downwards, and carries at its apex the writing style The pendulum bob is a flattened cylinder, supported by a placfont wire 1 50 m long. The amplifying lever at the junction of the three pyramidal and the prismatic tubes supports three radial arms meeting in the centre, as it were, of the pyramid base, and support a ball-and-socket joint of agate, the cup part of which is at the end of an arm projecting from the supporting wall Immediately above this centre, and occupying the prism space of the lever, is the cylindrical box, the wire supporting which passes through a small hole in the centre of the base of the prism We thus have a simple lever of the first order of light girder work It is prevented from rotating in azimuth by including some steel wire permanently magnetized

The style has been modified by lightening it and making it more rigid and non oxidizable, which is done by using a capillary glass tube

The registering apparatus is a smoked glass plate, supported over a clock, started at the moment of the earthquake by a seismoscope To prevent the complex figures of the ordinary registration in a pendulum seismograph, the author has arranged so that the plate shall rotate through a segment of a circle every three seconds, so as to bring a fresh surface of smoked glass beneath the style

Some modifications are then described. The principal one is making the bob annular, carrying a suitable aperture, in which is engaged the short end of a lever This lever is composed of three very thin brass tubes, graduating away smaller from the fulcrum, which is a gimbal joint such as suggested by the reviewer some years since in NATURE. This lever carries at its lower and longer end the style which records on the glass plate as in the original one described in this memoir

Another modification is a combination of the triple and single suspension of the pendulum bob, that is, the bob ring is first suspended by triple wires to a button which in its turn hangs at the end of a single wire

The details of these seismographs are fairly well worked out, but the employment of aluminium in many of the parts has been neglected Likewise, no arrangement has been made for the oblique play of the engaged pinion in the newer lever The only new point about this seismograph is the interrupted rotation of the recording plate This has a decided advantage in giving a dissected record, but is part counterblanced by the fact that important movements that may be taking place at the moment

[1] G. Agamennone, "Sopra un Nuovo Pendolo Sismografico" *Annali dell' Ufficio Centrale Meteor e Geodinamico*, ser sec, pt 3, vol xi., 1889. (Roma, 1892)

of the advance are represented by a curve or curves which would require a series of careful experiments to be carried out in each instrument, followed by difficult and elaborate calculation for each advance

Much credit is due to the author for working out the modifications, but until we have some original method of finding a steady-point, not so far suggested, it is doubtful if we can improve on the Gray, Ewing, and Milne seismographs, that are not, as the author imagines, little used or tested instruments.

H J JOHNSTON LAVIS

PHYSICAL GEOGRAPHY AND CLIMATE OF NEW SOUTH WALES

A SECOND edition of an excellent pamphlet on the "Physical Geography and Climate of New South Wales," by Mr H C Russell, F R S, astronomer royal for New South Wales, has just been issued at Sydney It is published by authority of the New South Wales Government The following extracts may be of interest to various classes of readers in Great Britain —

Looking back through the pages of history, and the dim traditions of an earlier time, we find abundant evidence of a belief in the existence of a great south land to the south and east of what was then the well known earth Those early navigators whose travels had fostered this belief, had doubtless followed down the Malay Peninsula and the string of islands which seem to form part of it, in search of spices and other treasures which the islands supplied Pliny, who had evidently gathered up the traditions of "Terra Australis incognita," says that it lay a long way south of the Equator, and in proof of this mentions the fact, strange in those days, that when some of its inhabitants were brought to civilization they were astonished to find the sun rise on their left hand instead of on their right And Ptolemy, A D 170, after describing the Malay Peninsula, says Beyond it, to the south-east, there was a great bay in which was found the most distant point of the earth, it is called "Cattigara," and is in latitude 8½° south, "thence (he goes on to say) the land turns to the west, and extends an immense distance until (as he believed) it joins Africa" And it may fairly be assumed that the extreme south latitude of Cattigara, and its situation in a great bay where the land turns to the west until it joins Africa, is proof that it was some point in the Gulf of Carpentaria, for no other place would fulfil the conditions The idea that the land actually reached Africa was not Ptolemy's, it was a necessary part of the system of Hipparchus, for he taught that the earth surrounded the water and prevented it from flowing away It is not surprising, therefore, that the early navigators, following down the islands, came at length to that part of the Gulf of Carpentaria where the land turned to the west, and believing Hipparchus' system of geography, thought that in turning to the west they were in reality turning towards home, and Cattigara was therefore the most distant point known Marco Polo tells us that the Chinese navigators in his day (A D 1293) asserted there were thousands of islands in the sea to south of them, and in the present day we find proofs of their early visits to Australia in the traces of Chinese features amongst the natives of the northern coast, indeed, some historians think that Marco Polo, in the account he gives of the expedition sent to Persia by the Great Khan, refers directly to Australia, under the name of Lochac This place he says was too far away to be subjugated by the Great Khan, and was seldom visited, but it yielded gold in surprising quantity, and amongst other wonders contained within it an immense lake or inland sea. It is impossible that such a description should apply, as has been thought, to the Malay Peninsula,—a country within easy reach, and one which his ships must have passed in every voyage, and so far from being beyond his power, it was within the limits over which his sway extended That Lochac formed part of the main land was also quite in accordance with their ideas of the earth, which surrounded the ocean, and the abundance of gold is certainly more likely to be true of Australia than of the Malay Peninsula

For long years after Marco Polo we find no direct reference to Australia, except the stories which lived amongst navigators, and seemed to lose none of their marvellous points by transmission These kept alive the desire to explore the great south land, so rich in treasures and wonders. All the evidence collected so far goes to prove that the Portuguese had, early in the sixteenth century, explored at least the northern parts of Australia What they learned was, however, kept a profound secret until about 1540, when one of their government maps was stolen, and there are now in existence six maps believed to be copies of it, which were all published between 1539 and 1555 These all show Australia under the name of the "Land of Java," the real Java being called the "Little Java," and from this time onward frequent attempts were made to explore what had for so many generations been "Terra Australis incognita" Sturdy navigators could not understand the silence of the Portuguese, except as proof of the richness of the land, about which tradition told wonderful tales "It was a land of gold and spices, of magnificent tropical fruits and vegetation—a perfect paradise, in which the happy and simple inhabitants were loaded with jingling ornaments of gold Its very atmosphere was elixir, and existence a round of enjoyment" No wonder that in an age when, at least upon the ocean, the power to take was mistaken for the right to do so, there were many who cast longing glances towards the southern Paradise Whether these stories of gold had any foundation in fact or not, when barter was regularly exchanged on the coast of Australia, it is impossible now to say, but more recent discoveries of rich surface gold lend some colour to them, and the vegetable richness of the northern part of Australia is quite in accordance with tradition But all the early English navigators were unfortunate, and Australia got a reputation the very reverse of what further investigation has shown that it deserves In point of fact, all the glowing colouring of tradition is true, but when Dampier, in 1688, sailed down the western coast, he saw nothing but a "dry sandy soil," and the "miserablest people in the world", and later on, when the first English settlers landed on Australia, they chose a bay, beautiful to look at, but there was no gold and no fruit worthy of the name, the soil was barren and sandy, and the climate in the worst part of its summer No wonder that the fame of Australia was blackened, and report made it a miserable land, subject to droughts and floods—a land in which everything was turned topsy-turvy The summer came at winter time, trees shed their bark, not their leaves—were brown instead of green, the stones were on the outside of the cherries, and the pears, pleasant to look at, were only to be cut with an axe, and there was nothing to eat, "unless, perchance, ye'l fill ye with root of fern or stalk of lily" Such was the early verdict upon Australia. Fortunately the first colonists, once here, were obliged to stop By degrees they found that everything that was planted grew well, that wheat in the valley of the Hawkesbury yielded 40 to 50 bushels to the acre, and in one memorable season actually ruined the farmers by its very abundance, for in the then limited market, the price fell so low that it was not worth gathering, and it was left in the fields to rot, while the farmers sought other work. Horses, sheep, cattle, and pigs throve marvellously, and some of the cows getting away, the bush soon contained numbers of wild cattle Even wool did not deteriorate in the new Colony, and step by step the facts became too strong for prejudice, and the first fleeces of Australian sheep sent to England lifted the veil Manufacturers would gladly take as many as could be sent, their demand for more wool extends with the supply, and now only from Australia can they obtain the fine wools which they need Quantity and quality of wool have increased together, and the Grand Prize at the Paris Exhibition for our New South Wales wool has proclaimed the fact far and wide Wool has done still more for the Colony We took possession of it as a narrow strip of coast country, the demand for pasture forced us to find a way over a hitherto impassable range, and the same want has driven all the desert out of the Colony, and covered it with sixty two millions of valuable sheep (1892) The country which early writers upon Australia called a barren waterless desert is now growing the finest wool and yielding abundant water from wells, and when, in 1851, it was announced that gold had been discovered in abundance, the world was convinced that Australia was a promising country after all Year by year the people have been coming in increasing numbers to supply our great want (population), and as our numbers increase new avenues of wealth and prosperity are opening before us

Geographically, Australia has a grand position, lying between the 10th and 40th degrees of south latitude—that happy mean where it is neither too hot nor too cold Surrounded by the ocean, the sea breezes temper what might otherwise be a hot climate in the summer, the air is clear and dry, and yet brings rain in heavy showers. Vegetation is abundant, and includes

all the cereals and fruits of the world, so that, in the words of the old tradition, it has "all the conditions which make life a pleasure"

Australia measures from north to south 1900 miles, and from east to west 2400 miles, and speaking generally, has a rounded outline, the only great inlets on the coast line being the Gulf of Carpentaria and the Australian Bight. The total area is rather greater than that of the United States, and almost equal to the whole of Europe. On the east, north, and west, and at a short distance from the coast are found ranges of mountains, of no great elevation, yet almost the only high land. On the west and north-west coasts the mountains form a bold outline of granite, rarely more than 200 miles from the coast, and attaining to heights of 2000 to 3000 feet. Between these and the sea the land is low and good, but on the inland side is found a vast table land which slopes towards the unknown interior so gradually that the inclination is not easily seen, and no rivers running to the interior have yet been discovered—all known streams running to the sea.

On the east coast we have also the mountain chain parallel to the coast, but it is much higher and more extensive, and the strip of low land by the coast is much narrower, often not more than 30 miles wide, and at Point Danger the range comes right to the sea. This grand chain of mountains is known generally as the Great Dividing Range, and extends for about 1500 miles along the east coast. Near its southern extremity is the Snowy Range, the only spot in Australia where snow may always be found. The highest peak, Mount Kosciusko, 7170 feet, is also the highest land in Australia. The ravines on its sides always contain snow, and the mountains near it, about 6000 feet high, are also covered with snow for the greater part of the year.

Of this great continent island, the Colony of New South Wales holds the choicest portion—the southern part of the east coast—the part where, with remarkable sagacity, the first settlement was made. It has the best climate, all the most important rivers in Australia, the great bulk of the coal land, unlimited stores of all the useful minerals, and the finest pastoral and agricultural lands for extra-tropical vegetation, besides which, its extensive highlands afford climatic conditions for all purposes. It is naturally divided into three portions. The comparatively narrow coast district, from 30 to 150 miles wide, abundantly watered by rivers and smaller streams coming down from the mountains. The rainfall here, fed by winds from the Great Pacific Ocean, is very abundant, from 40 inches in the south to 70 in the north, and at Sydney 50 inches. The mountains have doubtless very much to do with this abundant precipitation, and at times the rains are so heavy that the rivers, fed by mountain torrents, carry heavy and dangerous floods. In years past wheat was largely and profitably grown, but rust has of late so frequently appeared that little or no wheat is grown, for it pays better to supply the city markets with dairy produce, Indian corn, and various kinds of hay. In the northern districts sugar-growing is a profitable industry, and increasing rapidly. About Sydney enormous quantities of oranges are grown for exportation.

The second division includes the mountains and elevated plains, and extends the whole length of the colony, varying in width from 120 to 200 miles. On the south, with the exception of the Monaro Tableland, the country is very rough and mountainous, the highest points, Mount Kosciusko and the Snowy Range, catch the rain and snow that feed the river Murray and the Murrumbidgee. Wheat grows well here, but nearly all the land is used for pastoral purposes. Proceeding northwards, the mountains decrease in height and extend laterally. A part of the land is taken up for agriculture, some for mining. In its natural state the western country is open plain or lightly-timbered, and large areas are covered with rich volcanic soil which seems fit to grow anything, but the want of labour and carriage, and the profit and security to be found in raising wool and meat, has for the most part tempted capital into squatting pursuits, but since the railway has reached this part of the country more attention is being given to agriculture, and it is rapidly extending. Between Goulburn and Bathurst, the western waters form the Lachlan and the eastern the Hawkesbury rivers, and from Bathurst northwards to latitude 25° all the western waters go to form the various tributaries of the Darling river. These mountains are from 2000 to 3000 feet, with some peaks rising to nearly 6000 feet. The central parts of the western slopes are celebrated for rich soil and herbage, and here also the greater part of the gold mining area, as well as mines for other minerals have been found, including coal, which is also found in great abundance, with iron and lime, at Lithgow and other places. Deposits of copper, silver, lead, tin, and mercury are also found in abundance. A very large portion of the high land here is suitable for agriculture, and is being taken up for that purpose by degrees. English fruits—the apple, cherry, currant, &c.—grow to perfection here, as well as in other parts of the mountain districts.

The third division covers by far the greatest area, and consists of the Great Western Plains, extending away to the Darling river, and thence to the south Australian border. Here there are but few known mineral deposits except copper, and the enormous deposits of silver and lead at Broken Hill, and no attempt at agriculture. All the land may be said to be held for grazing purposes, and for that purpose, now that capital has been invested in tanks and wells for water supply, this country is unequalled. Sheep and cattle thrive in a remarkable degree, and form a most profitable investment, the climate being dry and wonderfully healthy for man and beast.

These are the three great natural divisions, made so by the conformation of the land and the climate. It will be evident from what has been said of the elevation of the mountains that snow is not a common feature upon them, and the only part where snow lies for any considerable time is the extreme south. As a necessary consequence, the river system is peculiar; indeed, it has often been asserted that Australia had no rivers—at least none which were of any use as such, but as we shall presently see, this statement, like many others affecting Australia, was made in ignorance. The necessity for increased pasture had driven the early colonists to cross the Great Dividing Range, aptly so named, in search of pasture, in 1815, and the desire to extend the new pastures beyond the Bathurst Plains, which were the first discovered, led them on, and one of the first questions that demanded their attention was to account for the direction in which all the streams were flowing. The shortest road to the sea was to south-west, and yet all the water was running to north west, and quite naturally it was asked—Could there be a great inland sea into which these rivers discharged? In 1818 Oxley started with a determination to see where at least one of them went to; so he followed the Macquarie for more than 200 miles, and found that he was going due north west, further and further, as it seemed to him, from the natural outlet on the south coast. At last the river spread out to an apparently interminable marsh. Turn which way he would his progress was stopped by a shallow fresh-water sea, for sea he was at last convinced it must be, so great was its extent, and he was obliged to turn back. He had got there after two very wet seasons (1817 and 1818), and his inland sea is now known as the Macquarie Marshes, and the mystery was not solved until Sturt, in 1829, found all these streams trending to north-west unite in the Darling, and then turn to south west.

Coming from mountains of such moderate elevation, these streams are necessarily dependent upon the rainfall, and have no snow to help them, so that in rainy seasons they become important rivers and in dry ones sink into insignificance, but since most of the rains which feed these waters are, as it were, offshoots of the tropical rains, they seldom fail altogether, and as a rule the Darling is navigable for four months of each year, and sometimes all through the year, up to and beyond Bourke. The current is very slow, seldom reaching two miles per hour, and therefore offers little hindrance to the steamers which carry wool and stores.

In the exploration of our rivers there was another surprise when settlement extended south-west from Sydney. The waters here were found to flow to the west, and the Lachlan has for a considerable portion of its course a south west direction, that is, at right-angles to the Macquarie and the Bogan. Could the Lachlan, the Murrumbidgee, and the snow-fed Murray ultimately join the waters that ran north west from Bathurst? Sturt had not solved this question—he only followed the Darling part of the way down—and it was left for Sir Thomas Mitchell to find the junction of the two river systems in 1835, and to prove that the Darling and the Murray were united at and below Wentworth.

After dealing with the rivers and harbours of New South Wales, Mr. Russell discusses the temperature, rainfall, droughts, and winds of the colony. Of the temperature he says:—

In works of reference, Australia generally is credited with heat in excess of that due to its latitude. It is difficult to say why, unless it arose from a habit of one of our early explorers who carried a thermometer and carefully published all the high, and none of the low readings he got, until, fortunately for the colony, the thermometer was broken and the unfair register stopped. But not only the interior—Sydney even to the present day is credited, in standard works of reference, with a mean temperature of 66·2°, or more than three degrees higher than the true mean, which is 62·9°. Such an error is not excusable when meteorological observations have been taken and published for just forty years. There is another error made by some writers when describing Australia. It is shown by them inverted on the corresponding latitudes in Europe, and the reader naturally infers that Australia is as hot as those parts of Europe. Confining our attention to New South Wales, that is between 29° and 37° of south latitude, we find that generally it is cooler than a corresponding part of Europe. The mean temperature of the southern parts of England is about 52°, and that of France, near Paris, about the same, increasing as you go south to 58·5° at Marseilles. Taking this as a sample of the best part of Europe, let us see how the mean temperatures in the colony compare with those. Kiandra, our coldest township, situated on a mountain, is 46°; Cooma, on the high land, 54°; Queanbeyan, high land, 58°; Goulburn, high land, 56°; Armidale and New England district, 56°; Moss Vale, 56°; Kurrajong, 53°; Orange, 55°. These towns are scattered along the high table lands from south to north, and represent fairly the climate of a very considerable portion of the whole colony. Next to this in point of temperature is the strip of land between the ocean and the mountains, and which is affected by the cooling sea-breezes. Here we have a mean temperature ranging from 60° at Eden, the most southern port, to 68° at Grafton, one of the northern ports. Sydney, in latitude 34°, has a summer temperature only four degrees warmer than Paris, which is in latitude 49°. Now the usual difference for a degree in latitude is a degree in temperature, and therefore, if Sydney were as much warmer than Paris as its latitude alone would lead us to expect, its temperature should be 74°, and that is 15° warmer than Paris; but as we have seen, it is only 4° warmer. This single example is enough to prove the comparative coolness of our coast districts. The investigation made during recent years shows that the mean temperature of the whole colony, as derived from forty five stations scattered over it, is 59·5°, three degrees lower than that of Sydney, or only one degree hotter than that of Paris.

It may be mentioned that the highest shade temperature ever recorded in Sydney was 106·9°, and near Paris a temperature of 106·5° has been recorded.

The third great district, consisting of lower land and plains to the west of the mountains, has a climate considerably warmer in summer than the parts above described, owing to the powerful effect of the sun on land having little forest and little or no wind; but in winter the temperature sinks down much lower than the coast districts, owing to the great radiation; so that the annual mean temperature is not so great as the summer heats would lead one to anticipate. A table has been prepared for the purpose of showing by comparison with many places in Europe and America the temperature of the colony. The places have been arranged in order of temperature, taking for that purpose the mean annual temperature. This shows at once that the range of temperature here is equivalent to that offered by Europe from the north of England through France to Sicily. Such a range is more remarkable, because if New South Wales were placed on the map of Europe according to its latitude it would extend from Sicily to Cairo, whereas when placed by its temperature it stretches as we have seen from Sicily northwards to England. Nor is this all that the table shows us. For even when we find a place in Europe with a temperature equal to that of some place here, it is at once observed that the summer temperature in Europe is warmer than the colonial one and the winter colder; for instance, Naples, 60·3°, Eden, 60·3°, summer at Naples, 74·4°; at Eden, 67·9°, winter at Naples, 47·6°, Eden, 51·9; and so generally the southern country has the cooler and more uniform temperature. It is worthy of remark that the only places here of equal mean and summer temperature with places in Europe are those which are to be found on the western plains, as at Wagga Wagga, which has a mean temperature of 60·3°; Naples, 60·3°; and summer temperature of both is 74°; or again, to compare the places of the same or nearly the same latitude, Messina, in Sicily, latitude 38° 11′, has a mean temperature of 66°, summer 72·2°, winter 55°; Eden, New South Wales, in latitude 37°, has a mean temperature of 60·3°, summer 67·9°, winter 51·9°, or Cairo, in latitude 30°, mean of 72°, summer 85·1°, winter 58·2°, Grafton, latitude 29° 45′, mean 68·1°, summer 76·8°, winter 58·4°. It is useless to multiply examples,—we have here enough to show how much cooler Australia really is than the fervid imaginations of some writers have made it appear in print.

Looking at this question of temperature generally, it will be seen that New South Wales is no exception to the general deduction of science that the southern lands are cooler than those of corresponding latitudes in the north, and it is only during hot winds, which are very rare in New South Wales, that the temperature rises to extremes. But to leave Europe, and compare the climate of New South Wales with that of America. Our limits of latitude would place us from Washington to New Orleans. Now the mean temperature at Washington is 55° and at New Orleans 68°, while that of Eden is 60·3° and Grafton 68·1°, so that if mean temperature were a complete test of climate it would appear that our coast is hotter than corresponding latitudes in America. But mean temperature is not enough; we must compare the summer and winter temperatures, and summer at Washington rises to 76·7° and at Eden only to 67·9°, 9° cooler; New Orleans summer is 82° and Grafton 76·8°, but 82° hardly represents the summer heat at New Orleans, for it is a steady broil, during which every day for three months of summer the heat is over 80°, a temperature that is only reached on this coast during hot winds, or in other words, very seldom. But winter temperature at Washington falls to 37·8°, and at New Orleans to 56°, at Eden 51·9°, and at Grafton 58·4°. Hence it is evident that on this coast the heat is very much less in summer and greater in winter than upon the coast of America. Such facts place the colony in a very different position in regard to climate from that which it has occupied in published works, for instead of being a hot country we see that its coast districts are much cooler than corresponding latitudes in Europe and America, and that in its elevated districts, which comprise a large part of it and much of the best land, it has a climate no warmer than the best and most enjoyable parts of Europe in much higher latitudes; but while bringing these facts into due prominence it is not the intention to deny that another considerable part of the colony, forming the western plains, is subject to greater heat, caused, no doubt, by the sun's great power on treeless plains, and the almost total absence of cooling winds; yet, although in summer the temperature here frequently rises over 100°, and sometimes up to 120°, yet, owing to the cold at night and in winter, the mean temperatures are not greater than those of corresponding latitudes in the northern hemisphere; and this part of the colony being remarkably dry, the great heat is by no means so enervating as a temperature of 80° in the moist atmosphere of the coast, and, what is of still more importance, it does not produce those terrible diseases which are usually the offspring of hot countries. This is also, no doubt, due to the dryness of the air. Stock of all kinds thrive remarkably well, and are very free from disease in those hot western districts.

SCIENTIFIC SERIALS

THE *Quarterly Journal of Microscopical Science* for August 1892 contains:—On the anatomy of *Pentastomum teretiusculum* (Baird), by Prof. W. Baldwin Spencer, M.A. (Plates i. to ix.) Whilst collecting on Kings Island, which lies to the west of Bass Straits, half-way between the mainland of Victoria and Tasmania, numerous specimens of the copper-head snake (*Hoplocephalus superbus*) were found, in the lungs of which a large species of Pentastomum were parasitic; afterwards the same parasite was discovered in the lungs of the black snake (*Pseudechys porphyriacus*) in Victoria; on examination there seemed little doubt but that the species was the one described by Baird long ago (1862) from specimens obtained in the mouth of a dead copper-head snake in the Zoological Gardens, London, under the name of *Pent. teretiusculum*. In this paper we have a very complete account of the anatomy of this form, there being descriptions and figures of its external anatomy, schematic

representations of the muscular, alimentary, secretory, nervous, and reproductive systems, and an account of the sense organs. The paper is illustrated by ten double plates —On the minute structure of the gills of *Palæmonetes varians*, by Edgar J. Allen, B Sc (Plate x) It would seem that so far as the gills of this crustacean are concerned, the statement made by Haeckel and Ray Lankester, that the circulatory system of the Decapods is everywhere closed, does not hold true It would also seem fairly certain that the masses of cells surrounding the venous channels, in which Kowalevsky found litmus deposited a few hours after its injection, exercise an excretory function In addition to these excretory cells, a large number of glandular bodies occur in the axis of the gill, and these are of two kinds—clear and reticulate glands.

The number for November 1892 contains —On the development of the optic nerve of vertebrates, and the choroidal fissure of embryonic life, by Richard Assheton, M A (Plates xi and xii) That the optic nerve is formed by the differentiation of the cells of the optic stalk into nerve fibres, which consequently lose connection with the inner wall of the optic cup, and piercing the outer wall, make connection with the outer face thereof, is held to be probable by such writers as Balfour, Foster, Marshall, Haddon, and others, whilst the opinion that it is formed by the growth of nerve fibres either from the retina (outer wall of the optic cup) or from the brain, along the optic stalk, but outside it and unconnected with it, is or has been held by His, Müller, Kolliker, Hertwig, Orr, and has been recently supported by Keibel, Froriep, and Cajal Schafer seems to be uncertain which view to take As the result of the author's investigations in the frog and chick, he concludes that the optic stalk takes no part in the formation of the nervous parts of the organ of sight The optic nerve is developed independently of the optic stalk, and at first entirely outside it The great majority of the fibres forming the optic nerve arise as outgrowths from nerve cells in the retina.—On the larva of *Asterias vulgaris*, by George W Field, M A (Plates xiii to xv) —On the development of the genital organs, ovoid gland, axial and aboral sinuses in *Amphiura squamata*, together with some remarks on Ludwig's hæmal system in this ophiurid, by E W MacBride, B Sc (Plates xvi to xviii) Concludes that echinoderms agree with other cœlomata in the origin of their genital cells these latter have at first an unsymmetrical position in echinoderms, and afterwards take on a radially symmetrical disposition in correspondence with the secondarily acquired radial form of the body. The origin of these cells adjacent to the stone canal suggests a comparison of the origin of the genital cells near the nephridia in many annelids, but the homology of the stone canal with a nephridium has yet to be proved —On a new genus and species of aquatic Oligochæta belonging to the family Rhinodrilidæ, found in England by W B Benham, D Sc (Plates xix and xx) This new worm receives the name of *Sparganophilus tamesis*, it was found in some numbers in the mud of the Thames, adhering to the roots of *Sparganium ramosum*, near Goring; the cocoon is drawn out to a point at one end, while in the other it shows a narrow frayed end. As the home of the Rhinodrilidæ is America, the author suggests that the cocoons of this worm may have been introduced into the Thames amongst the roots of water plants, or attached to timber from the United States

American Meteorological Journal, December —Atmospheric electricity, earth currents, and terrestrial magnetism, by Prof C Abbe The author has collected from various telegraph companies particulars about electrical storms, which illustrate the magnitude of the disturbances that frequently occur. The present electrical and magnetic observatories, which usually observe only some part of the whole series of phenomena, need to be supplemented by completely equipped establishments recording continuously the north-south, the east west, and the zenithal-antipodal differences of potential The ordinary records of atmospheric electricity give merely the difference of potential of the earth and a point in the atmosphere defined as the end of the water-dropping collector.—Notes on the use of automatic rain gauges, by J E Codman. Observations were made continuously for three years with the object of showing what difference the size of the gauges would make in the amount of rainfall collected. The largest gauge had a diameter of over 22 inches, and the smallest 2 inches. The results show that the size of the gauge made no practical difference He also gives the results of rainfall collected in gauges erected at various heights on a mast The result showed that a gauge at an elevation of 50 feet or less above the surface of the ground will collect the same amount as one on the ground, provided both are situated in a position not affected by counter currents of air This result agrees with that found by Prof Hellmann in his experiments at Berlin —Sunshine recorders, by Prof C F Marvin Thus far two methods only have been in general use, (1) the focussing of the rays of the sun by means of a glass sphere and obtaining a burn on the surface of a card, and (2) the photographic method, producing a trace on sensitized paper The first method records only bright sunshine, while the latter method is more sensitive and records fainter sunshine Prof Marvin has improved a method first developed by D T Maring of the Weather Bureau, consisting in principle of a Leslie differential air thermometer, mercury being used to separate the air in the two bulbs When properly adjusted and exposed to sunshine the lower blackened bulb becomes heated and causes the column to rise above a platinum point and close an electric circuit The instrument, of which a drawing is given, is said to respond promptly to sunshine and shadow The other articles are —Late investigation of thunderstorms in Wisconsin, by W L. Moore —Observations on the aurora of July 16, by T. W Harris, and Temperature sequences, by Prof H A Hazen

THE articles in the *Journal of Botany* for November and December are mostly of interest to students of British botany Mr F J Hanbury adds two more to his new species of *Hieracium*, *H britannicum* and *H caniceps*, Mr Bagnall describes a new species of bramble, *Rubus mercicus* from the Midland counties, and Mr. W H Pearson a new British liverwort, *Scapania aspera* Mr G F Scott Elliot contributes some useful hints on botanical collecting in the tropics

SOCIETIES AND ACADEMIES

LONDON

Royal Society, December 8, 1892 —"On the Photographic Spectra of some of the Brighter Stars" By J Norman Lockyer, F R S

The present communication consists of a discussion of 443 photographs of the spectra of 171 stars, which have been obtained at Kensington and Westgate-on Sea during the last two years

The chief instrument employed in this work has been a 6 inch refracting telescope in conjunction with—at different times—objective prisms of $7\frac{1}{2}°$ and $45°$ respectively

By this method the time of exposure is short, and good definition, with large dispersion, is easily secured The spectra thus obtained will bear enlargement up to thirty times without much sacrifice of definition

The 30-inch reflector and slit-spectroscope at Westgate on-Sea have also been used in the inquiry

My object has not been so much to obtain photographs of the spectra of a large number of stars as to study in detail the spectra of comparatively few

In the classifications of stars adopted by others from a consideration of the visual observations, only the broader differences in the spectra have been taken into account. Prof Pickering has more recently employed a provisional classification in connection with the Henry Draper Memorial photographs of stellar spectra, but this chiefly relates to photographs taken with small dispersion. With larger dispersion it becomes necessary to deal with the presence or absence of individual lines.

In the first instance, the various stars of which the spectra have been photographed at Kensington have been arranged in tables, without reference to any of the existing classifications, and taking into account the finer details The basis on which the main tabular divisions of the spectra are founded is the amount of continuous absorption at the blue end This distinction was not possible in the case of the eye observations.

The stars included in the first table are characterized by the absence of any remarkable continuous absorption at the blue end, and by the presence in their spectra of broad lines of hydrogen These have been further classified in four sub-divisions, depending on the presence or absence of other lines

In the stars of the second table there is a considerable amount of continuous absorption in the ultra-violet, and the spectra beyond K are very difficult to photograph as compared with the stars of the first table In these stars the thickness of the hydro-

gen lines is about the same as in the solar spectrum These also are arranged in two sub divisions

In all the stars included in the third table there is a very considerable amount of continuous absorption in the violet, extending to about G, and it is a matter of great difficulty to photograph these spectra, as most of the stars of this class are below the third magnitude The hydrogen lines are very thin. One sub division includes the spectra which show flutings shading away towards the less refrangible end of the spectrum. The other comprises stars without flutings in their spectra The brightest star in this table, α Orionis, is discussed in detail, the result tending to show that the temperature of the absorbing iron vapours is not much greater than that of the oxy hydrogen flame

The relations of the various sub-divisions to which reference has been made are then traced

One important fact comes out very clearly, namely, that whether we take the varying thicknesses of the hydrogen lines or of the lines of other substances as the basis for the arrangement of the spectra, it is not possible to place all the stars in one line of temperature Thus, there are stars in which the hydrogen lines are of the same average thickness, while the remaining lines are almost entirely different These spectra cannot, therefore, be placed in juxtaposition, and it is necessary to arrange the stars in two series

The next part of the paper consists of a discussion of the photographic results in relation to the meteoritic hypothesis In the Bakerian Lecture for 1888, I brought together the various observations of the spectra of stars, comets, and nebulæ, and the discussion suggested the hypothesis that all celestial bodies are, or have been, swarms of meteorites, the difference between them being due to different stages of condensation The new classification rendered necessary by this hypothesis differed from previous ones, inasmuch as the line of evolution followed, instead of locating the highest temperature at its commencement, as demanded by Laplace's hypothesis, placed it much later Hence bodies of increasing temperature were demanded as well as bodies of decreasing temperature

The question how far this condition is satisfied by the new facts revealed by the photographs is next discussed

This involves the consideration of some points in connection with the hypothesis to which brief reference alone has been made in previous communications. The phenomena to be expected on the hypothesis, and the actual facts, are given side by side below —

Nebulæ.

The bright lines seen in nebulæ should have three origins :—	
(1) The lines of those substances which occupy the interspaces between the meteorites Chief among these, from laboratory experiments, we should expect hydrogen and gaseous compounds of carbon.	(1) Lines at wave lengths approximately very closely to the lines of hydrogen, and to some of the carbon flutings, appear in the spectra of nebulæ
(2) The most numerous collisions between the meteorites will be partial ones—mere grazes—sufficient only to produce comparatively slight rises of temperature.	(2) There is a fluting most probably due to magnesium at λ 500, and the longest flame lines of iron, calcium, and magnesium are seen
(3) There will, no doubt, be a small number of end on collisions, producing very high temperatures, and there should be evidence of some high-temperature lines.	(3) The chromospheric line D_3 and another line at λ 4471 (which is always associated with D_3 in the chromosphere) have been recorded in the spectrum of the Orion Nebula.

Bright-Line Stars

The lines seen in the spectra of bright-line stars should, in the main, resemble those which appear in nebulæ. They will differ, however, for two reasons given in the paper	Prof Pickering has shown that the Draper Memorial photographs prove that bright-line stars are intimately connected with the planetary nebulæ, the lines in the spectra being almost identical.

Stars of Increasing Temperature

Stage 1 —Immediately following the stage of condensation giving bright line stars, the bright lines from the interspaces will be masked by corresponding dark ones, due to absorption of the same vapours surrounding the incandescent meteorites, and these lines will therefore vanish from the spectrum	The spectra of stars given in the third table answer these requirements They show no bright lines under normal conditions
Owing to the interspaces being restricted, absorption phenomena will be in excess, and low-temperature metallic fluting absorption will first appear The radiation spectrum of the interspaces will now consist chiefly of carbon	The dark flutings in the visual spectrum agree very closely in position with the flutings seen in the flame spectra of manganese, lead, and iron The evidence afforded by the photographs proves the actual presence of carbon radiation
Under these conditions the amount of continuous absorption at the blue end will be at a maximum	The photographs show a considerable amount of continuous absorption in the ultra-violet and violet
Stage 2 —With further condensation, the radiation spectrum of the interspaces will gradually disappear, and dark lines replace the fluting absorption owing to increase of temperature, though this line absorption need not necessarily resemble that in the solar spectrum	The spectra consist of numerous dark metallic lines, but they do not exactly resemble the solar spectrum α Tauri and γ Cygni are types of stars at this stage
Stage 3 —(1) The line absorption and the continuous spectrum at the blue end will diminish as the condensations are reduced in number, as only those vapours high up in the atmospheres surrounding the condensations will be competent to show absorption phenomena in consequence of the bright continuous spectrum of the still disturbed lower levels of those atmospheres	(1) These conditions are satisfied by such stars as α Cygni, Rigel, Bellatrix, δ Orionis, and α Virginis In these there is no continuous absorption at the blue end, the spectra consisting of simple line absorption
(2) Lines of iron and other substances will disappear at this stage, because the bright lines from the interspaces will counteract the lines in the same positions due to absorption of surrounding vapours.	(2) In the spectrum of α Cygni, which represents the earliest example of this stage there are a few of the longest lines of iron, but in other stars of this class the iron lines disappear.
(3) The chances of violent collisions being now enormously increased, we should expect the absorption of very high temperature vapours The solar chromospheric lines may be taken as examples of lines produced at such temperatures	(3) The new lines which appear include the chromospheric line at λ 4471, and possibly a few others

The Hottest Stars

The order of the absorbing layers should follow the original order of the extension of the vapours round the meteorites in the first condition of the swarm, and the lines seen bright in nebulæ, whatever their origins may be, should therefore appear almost alone as dark lines.	In stars like α Andromedæ we have absorption lines agreeing in position with some of the bright lines which appear in nebulæ.

Stars of Decreasing Temperature

Stage 1 —Owing to the diminishing depth of the absorbing atmosphere, the hydrogen lines will, on the whole, get thinner, and new lines will appear. These new lines will not necessarily be identical with those observed in the spectra of stars of increasing temperature. In the latter there will be the perpetual explosions of the meteorites affecting the atmospheres, whereas in a cooling mass of vapour we get the absorption of the highest layers of vapours. The first lines to appear, however, will be the longest low temperature lines of the various chemical elements.	Taking Sirius as a type of stars in the first stage of decreasing temperature, it is found that its spectrum shows many of the longest lines of iron.
Stage 2 —The hydrogen lines will continue to thin out, and the spectra will show many more of the high-temperature lines of different elements. These will differ from the lines seen in stars of increasing temperature owing to the different percentage composition of the absorbing layers, so far as the known lines are concerned.	The conditions at this stage of cooling are satisfied by such stars as β Arietis and α Persei. In the spectrum of these stars nearly all the solar lines are found, in addition to fairly broad lines of hydrogen.
Stage 3 —With the further thinning out of the hydrogen lines and reduction of temperature of the atmosphere, the absorption flutings of the compounds of carbon should come in.	There is undoubted evidence of the presence of carbon absorption in the solar spectrum and the spectrum of Arcturus, the only star which has yet been investigated with special reference to this point.

The photographs, then, give us the same results as the one formerly obtained from the eye observations.

Comparison is then made between the groups in the classification first suggested by the eye observations, and the various sub-divisions in which the photographs have been arranged.

Geological Society, December 7 —W H Hudleston, F R S., President, in the chair —The following communications were read —Note on the Nufenen stock (Lepontine Alps), by Prof T. G Bonney, F R S. In 1889 the author was obliged to leave some work incomplete in this rather out of the-way portion of the Lepontine Alps. In the summer of 1891 he returned thither in company with Mr J Eccles, F G S, and the present note is supplementary to the former paper. The Nufenen stock was traversed from north to south, and a return section made roughly along the eastern bank of the Gries Glacier. Gneiss abounds on the north side of the Nufenen Pass, followed by rauchwacké and some Jurassic rock. On the flank of the mountain are small outcrops of rauchwacké and of the so-called "Disthene schists" (both badly exposed), followed by much Dark-mica schist, often containing black garnets. Higher up is a considerable mass of Jurassic rock with the "knots" and "prisms" which have been mistaken for garnets and staurolites, but Dark mica schists set in again before the summit is reached. They continue down the southern flank of the peak; but rather north of the lowest part of the water shed, between Switzerland and Italy, the "Disthene schist" is again found, followed by a fair-sized mass of rauchwacké. The return section gave a similar association in reverse order, and both confirmed the conclusions expressed by the author in 1890 as to the absence of garnets and staurolites from Jurassic rocks (with belemnites, &c), and the great break between these or the underlying rauchwacké (where it occurs) and the crystalline schists, in which garnets often abound, of the Lepontine Alps. The crystalline schists and the Mesozoic rocks are thrown into a series of very sharp folds, which, locally, presents at first sight the appearance of interstratification.—On some schistose "greenstones" and allied hornblendic schists from the Pennine Alps, as illustrative of the effects of pressure metamorphism, by Prof T G Bonney. The author describes the results of study in the field, and with the microscope, of (*a*) some thin dykes in the calc schist group, much modified by pressure, (*b*) some larger masses of green schist which appear to be closely associated with the dykes, (*c*) some other pressure modified greenstone dykes of greater thickness than the first. The specimens were obtained, for the most part, either near Saas Fee or in the Binnenthal. These results, in his opinion, justified the following conclusions —(1) That basic intrusive rocks, presumably once dolerites or basalts, can be converted into foliated, possibly even slightly banded, schists, in which no recognizable trace of the original structure remains. (2) That in an early (possibly the first) stage of the process, the primary constituents of the rock-mass are crushed or sheared, and thus their fragments frequently assume a somewhat "streaky" order, that is to say, the rock passes more or less into the "mylonitic" condition. (3) That next (probably owing to the action of water under great pressure) certain of the constituents are decomposed or dissolved. (4) That, in consequence of this, when the pressure is sufficiently diminished, a new group of minerals is formed (though in some cases original fragments may serve as nuclei). (5) That of the more important constituents hornblende is the first to form, closely followed, if not accompanied, by epidote, next comes biotite (the growth of which often suggests that by this time the pressure is ceasing to be definite in direction); and, lastly, a water clear mineral, probably a felspar, perhaps sometimes quartz. (6) That in all these cases the hornblende occurs either in very elongated prisms or in actual needles. The author brings forward a number of other instances to show that this form of hornblende may be regarded as indicative of dynamometamorphism, so that rocks where that mineral is more granular in shape (cases where actinolite or tremolite appears as a mere fringe being excepted) have not been subjected to this process —On a secondary development of biotite and of hornblende in crystalline schists from the Binnenthal, by Prof T G Bonney. Both the rocks described in this communication come from the Binnenthal, and were obtained by Mr J Eccles, F G S, in the summer of 1891. They belong to the Dark mica schists described by the author in former papers, and have been greatly affected by pressure. In each a mineral above the usual size has been subsequently developed. In the rock from near Binn this mineral is a biotite: the dimensions of one crystal, irregular in outline, and having its basal cleavage roughly perpendicular to the lines indicative of pressure, are about 175″ × 03″. The other mineral, from the peak of the Hohsandhorn, is a rather irregularly formed hornblende, the crystals (which lie in various directions) being sometimes more than half an inch long. The exterior often is closely associated with little flakes of biotite. The author discusses the bearing of this fact, and the circumstances which may have favoured the formation of minerals, so far as his experience goes, of an exceptional size. Some remarks also are made on relation of these structures developed in the Alpine schists to the various movements by which those rocks have been affected, and on the general question of pressure as an agent of metamorphism. The reading of these papers was followed by a discussion, in which the President, Mr Eccles, the Rev. E Hill, Mr Rutley, Mr Teall, and the author, took part —Geological notes on the Bridgewater District in Eastern Ontario, by J. H Collins.

PARIS

Academy of Sciences, January 2 —M d'Abbadie in the chair —M Lœwy was elected Vice-President for 1893. MM Fizeau and Fremy were elected into the central committee of administration. The President gave a list of the members, associates, and correspondents deceased and elected during 1892. The new members were MM Appell, Perrier, Guyon, and Brouardel. Foreign associates, MM von Helmholtz, and van Beneden. Correspondents, MM Sophus Lie, Considère, Amsler, Auwers, Rayet, Perrotin, de Tillo, and Manen — Observations of Brooks's comet (November 19, 1892) made with the *equatorial coudé* of the Lyon Observatory, by M G. Le Cadet.—On a new method of approximation, by M E Jablonski. —On the movements of systems whose trajectories admit of an infinitesimal transformation, by M Paul Painlevé —On the general form of vibratory motion in an isotropic medium, by M E. Mercadier.—On thermo-electric phenomena between two

electrolytes, by M. Henri Bagard. The thermo-electric force between two portions of the same electrolyte in different stages of dilution was determined by experiments performed at the physical laboratory of the Faculty of Sciences at Nancy The diaphragm employed consisted of goldbeater's skin, which has the advantage of closely adhering to the glass The results are given in the case of zinc sulphate With a 5 per cent and a 45 per cent solution the difference of potential ranged from 78 at 17 9° to 155 at 73 5°, the unit being 1/10000th of the E M F of a Daniell cell The law of intermediate bodies was strictly fulfilled, as shown by opposing a couple of 5 and 25 per cent in series with another of 25 and 45 per cent to a third of 5 and 45 per cent., when no deflection of the electrometer was observed between 0° and 73 3° —On the age of the most ancient eruptions of Etna, by M Wallerant The first eruptions of Etna have been variously estimated to have occurred in the later quaternary or in the upper pliocene periods These conclusions were based on the study of the prismatic basalt laid bare by the sea round the foot of the cone The pliocene deposits found in conjunction with part of the basalt appear from palæontological evidence to be contemporaneous with the sub-Appenine blue marls, which belong to the lower pliocene. In the Cyclopean Isles the basalt is covered with a layer of clay, which is also found interpenetrated by the basalt The identity of age of the two formations is evidenced by lenticular patches of sand interstratified in the clay, whose particles consist of fragments of pyroxene, peridote, and triclinic felspar, proving that when the sub-Apennine marls were being deposited Etna was the scene of eruptions accompanied by the emission of ashes

HEREDITY.

Das Keimplasma Eine Theorie der Vererbung. By August Weismann, Professor in Freiburg i B (Jena. Gustav Fischer, 1892)

IN the substantial volume whose title stands at the head of this article Prof Weismann has gathered together the results of the essays and researches which he has given to the world during the last eleven years, and he now presents us with a theory of heredity, for which his previous writings have been but preparatory

Those who have followed the German philosopher since the appearance of "Die Dauer des Lebens" in 1882 have traversed a wide territory They have seen many theories and hypotheses come into view and attain a certain degree of definiteness Some of these are now lost to sight, others have changed their outline and altered the relative proportion of their parts, but, whatever was the standpoint, the central feature of Prof Weismann's theory of heredity—the continuity of the germ-plasma—remained unchanged

The work before us consists of an introduction, partly historical, and of four books, in which the theory and its application to various biological problems are set forth in the fullest possible manner, and in language for the most part free of technical phrases, so that a non-scientific reader can easily follow the argument At the close of the volume are a summary of the four books and an index The latter is a novelty in a German book of this kind, for which we cannot be too grateful to its compiler, Fraulein Diestel

The title of the work strikes the key-note of Prof Weismann's theory Heredity, according to his view, is brought about by the transference from one generation to another of a substance with a definite and very complex constitution, the germ-plasma This substance is the material basis of heredity, and it is supposed that a part of it in each reproductive cell is not used up in the construction of the offspring, but is transmitted unchanged to form part of the reproductive cells of the following generation. As the author points out, his theory might be termed "Blastogenesis," or the origin from the germ-plasma, as opposed to Darwin's Pangenesis, or the origin from all parts.

This germ-plasma is necessarily a most complicated substance, it cannot arise anew, but can grow and increase. Its ultimate constituents, according to the latest view of the Freiburg professor, are certain units termed biophores, which possess the properties of assimilation, growth, and multiplication by means of fission So long as the organic world consisted of biophores living either singly or united in colonies, heredity and multiplication with subsequent growth were one, since each division resulted in two similar halves, which by growth gave rise to organisms exactly like the parent.

But, when the principle of the division of labour made itself felt, the biophores became differentiated, and simple division no longer sufficed to give rise to two similar organisms, each exactly like their parent. A special mechanism was needed to bring about heredity, and according to our author this was found in the nucleus This differentiated part of the cell was originally a collection of reserve biophores. After the division of the nucleus the biophores in each half multiplied, and so replaced those which had separated from them, and thus rendered possible the completion of the new organism The structure of the nucleus became still more complicated when amphimixis, the mingling of the hereditary substance of two individuals, made its appearance Amongst multicellular organisms, with their endless variety of cells, the same mechanism exists, but in a still more complicated form Sexual reproduction has arisen, that is, the "Anlagen" for the whole organism are collected into a single reproductive cell, two such cells come together, and the resulting fertilized egg cell contains the hereditary substance of two individuals.

According to Prof Weismann's present view, this hereditary substance or germ-plasma consists ultimately of biophores These units are built up in a definite order and arrangement into units of the second degree, which are termed "cell determinants," or simply "determinants" Every cell of a multicellular organism is dominated in its histological character, and in the rhythm and nature of its division by one of the determinants. Each cell has not, however, a corresponding determinant in the germ-plasma, but cells of the same sort, as, for instance, blood corpuscles, may be represented in the hereditary substance by the same determinant In the germ-plasma of any species there must be as many determinants as there are variable cells or cell groups in the organism The determinants are arranged in a definite order in units of the third degree termed "ids"

These ids, which will be familiar to readers of Prof Weismann's latest essay, that on Amphimixis, are again built up into idants, and these last probably correspond with the chromatosomes, or nuclear rods of the nucleus. Thus the germ-plasma consists of idants, the idants are composed of ids, the ids are built up in a definite manner of determinants, and the determinants are formed of the final units, the biophores.

It is assumed that the biophores can pass out of the nucleus and divide and multiply in the surrounding cell protoplasm Amphimixis brings about the mingling of a certain number of biophores from one parent with a similar number from the other, and the organism whose body is dominated by this mixed assemblage of biophores partakes of the nature of both parents.

In the reproductive cells of the higher plants and animals the nucleus must contain not only those determinants which dominate the structure, rate of division, &c, &c, of the cell itself, but also those which will dominate the various cells and systems of cells which will eventually arise from the reproductive cell, and furthermore these must be definitely arranged in a given order, so that they may not be all called into activity at once, but may become functional successively, in accord with the origin of the cells they control.

It is not possible within the limits of a short article to describe the many ingenious applications of his theory, by means of which Prof. Weismann attempts to explain such phenomena as the Regeneration of lost parts, Reversion, Budding, Alternation of Generations, &c.: all

these are brought into line, and are shown to be capable of an explanation in the theory of germ plasma. Dimorphism and seasonal dimorphism are explained by the assumed existence of double determinants, one corresponding with each form, and remaining inactive during the life-time of the organism controlled by the other.

Such changes as affect the cell body cannot be transmitted according to this view, since alterations in the cell have no effect upon the biophore which in the next generation will dominate the corresponding cell of the offspring. But, since variation must be ultimately dependent on external circumstances, influences such as climate, change of food, &c., are considered to have in the course of time some effect upon the determinants, and a corresponding change in the organism results. In this lies one of the chief differences between the germ-plasma theory of Prof. Weismann and the Pangenesis of Darwin. They both give a possible explanation of heredity, but in the latter case the gemmules, coming from every cell of the body, afford an explanation of the transmission of acquired somatic changes, in the former case the biophores, arising only from other biophores, would be uninfluenced by any such change.

A. E. S.

THE BASIS OF ALGEBRA.

The Algebra of Co-planar Vectors and Trigonometry. By R. Baldwin Hayward, M.A., F.R.S., Senior Mathematical Master in Harrow School, formerly Fellow of St. John's College, Cambridge. (London: Macmillan & Co., 1892.)

THIS work is constructed on the methods of the school of mathematicians who derived their inspiration from the teaching of De Morgan, a school which is represented by many of the most influential of our recent writers on mathematical subjects. It is intended to occupy the place of the "Trigonometry and Double Algebra," published in 1849 and now a long time out of print, at the same time incorporating such improvements in elementary treatment as have been evolved out of half a century's discussion of the foundations of Algebra. Those who are acquainted with Mr. Hayward's other writings, such as his "Elements of Solid Geometry," will expect a fresh and interesting treatment of his subject; and they will not be disappointed. On turning over the pages we constantly come across elegant touches and happy turns of expression, and historical appreciations—the stuff which constitutes the basis of literary excellence in mathematical writings.

The treatise is primarily concerned with the logical exposition and illustration of the principles on which Algebraic Analysis, including Analytical Trigonometry, is founded. The utility of this subject in its practical applications renders it a necessary part of even an elementary course of reading, while a very refined treatment of it may lead so far into the notions of the Theory of Functions and algebraic continuity in general, as to somewhat overlay the really simple matters with which it is concerned. In this country the tendency in elementary books has, until recently, been rather to take the fundamental formulæ on credit, and to make the subject consist of the development of their analytical and practical consequences. The philosophical principles which bind them into an organic whole have retained so much the aspect of *à posteriori* developments, that there is some temptation to proceed in the view that Mathematical Analysis is an inductive science like Natural Philosophy, that it is one part of the science to invent and verify the formulæ, while the logical calculus which gives them precision and limitation is quite another department. The great majority of readers of the elements of Algebra have no time for an exhaustive discussion of the nature of continuous quantity and all the types of singularity to which it is liable, while on the other hand complete neglect of the logical basis of Analysis deprives it both of a main source of its interest, and of a large part of its value as an intellectual training. Hence arises the importance, even in presence of the complete theory with which a specialist must be acquainted, of the simplification and improvement of methods of exact treatment within the domain of elementary ideas.

The author's method starts off from an *à priori* discussion of the Algebra of Co-planar Vectors, which leads him to the two modes of specification of a vector, as a power of the fundamental vector, and as a sum of components. The identification of these two expressions leads to the analytical definitions of the *sine* and *cosine*, and by way of certain theorems in algebraic limits [whose explicit enunciation is by the way not essential] to the orderly development of the subject. The theorems concerning series which involve the complex variable are strikingly illustrated by corresponding vector chains, and geometrical interpretations are throughout very copious. The treatment is here so full and many-sided, that it would form an interesting occupation for the reader to take up the other aspect of the matter, and try to pick out the simplest and briefest analytical foundation on which the formulæ required for practical applications may be built.

The remarkable formula of p. 115, $(4{\cdot}810475\ldots)^{\iota} = \iota$, if removed from the context in which it is set, might be propounded as a puzzle in interpretation. The author introduces us straight off to an expression with a complex index, and proceeds to ascertain whether any meaning can be assigned to it, which will allow the inclusion of such expressions in the algebraic calculus. The geometrical method gives him very neatly and definitely an expression for the values of A^B, where A and B are both complex, by means of the vector ribs of a fan of equiangular spiral form. But when the conception of logometers (analytical logarithms) to a vector base comes up for interpretation, the answer proves to be some one of an infinito-infinite series of vectors related to one another in a manner so complicated as to elude definite grasp; and we have arrived at a case in which the inclusion of the function in our calculus would, in the absence of special machinery of representation like a Riemann's surface, be best avoided.

The origin of all difficulty in the treatment of complex algebra lies in fact in the multiplicity of values of the functions with which it deals. If each function can be defined as spread out in a multiple sheet so as to be single-valued at each point on each leaf of the sheet, a great part of the trouble disappears. We can then if we

please make explicit use of the Principle of the Permanence of Equivalent Forms, which, after having been expounded at length and defended by Peacock (appendix to "Algebra"), has been summarily rejected as misleading and unmeaning by many recent authors To the formal reintroduction of this principle Mr Hayward's language exhibits a tendency to return Outside the domain of elementary Algebra, its strict employment in the prolongation of an analytical function into a new region is indeed of common occurrence in Analysis; while its tentative application in unrestricted form, as an instrument of suggestion and discovery in the Theory of Operations, is fundamental. To the effort to widen the limits of interpretation in connexion with it, has been due most of the advances in Analysis

It is a fundamental question in mathematical logic how far, after having carried the stream of our analysis through regions of uninterpreted symbols, and having at length arrived at a stage in which these symbols have disappeared, we are entitled to claim this procedure to be demonstrative It is of course of the very essence of Algebra that the intermediate steps of its analysis remain uninterpreted, though in the Algebra of real quantities we have a tacit assurance that an interpretation can be supplied if necessary Why then was there an objection to a similar procedure in the Algebra of complex quantities, and what is the source of the timidity and doubt which characterized the use of complex analysis before its geometrical interpretation was developed? Simply that complex quantities turned out to be multiple-valued, and that the selection of the proper value under given circumstances had to be settled by tracing the continuity of the quantities in a way that was to the mind practically impossible until a visual geometric representation was discovered. The Argand diagram is not essential to the logic of the matter, it rather makes Analysis possible by bringing its scope within our grasp It simply forms a more extensive and systematic example of the method which has been in use since the time of Descartes for studying functions and approximating to their roots, by aid of their graphical representation

The Principle of Permanence of Equivalent Forms thus lies at the very root of Algebra, but it is rendered ineffective by indeterminateness of interpretation Its strict use, when most needed, is subject also to another hitch. It requires that the forms be expressed in exact terms, an infinite series must be expressed in the sum of n terms together with a residue R These residues must be retained throughout the analysis until we arrive at a point where interpretation comes in, and it must then be settled how far they can be neglected in the circumstances of the actual interpretation. In the language of Mr Hayward, it cannot be asserted about series that are not absolutely convergent, that the fundamental laws of Algebra hold without limitation

It is perhaps a question how far the idea, thus restricted and safeguarded, is worth being expressly retained as a working principle of ordinary Algebra. In subjects like the Calculus of Operations and Finite Differences, which are still in an unsytematized stage, it cannot be dispensed with; and the extent to which its use is boldly pushed, by De Morgan and Boole, even to the discussion in an operational manner of divergent series without their residues, contrasts with the more exact processes of recent Analysis. How far this boldness arises from the profound logical studies of these writers, and their appreciation of the imperfect character of inference at the best, may be a subject open to discussion.

In connexion with the doctrine of convergence of series, the author gives a very clear account, from Sir G Stokes, of how it is that, on approaching certain critical points, the convergence may gradually fall off and finally disappear. The illustrations employed are algebraic series of an exceptional character, and the whole circumstances may possibly suggest to the uninitiated that it is a phenomenon of exceptional rarity The most natural context is, of course, in connexion with the wonderful and far-reaching theory initiated by Fourier, by means of which functions arbitrarily discontinuous are expressed by seemingly continuous series In that connexion, the necessity of explanation is so obvious that it is interesting to examine the previous attempts at elucidation Thus De Morgan, in 1839, is able to conclude ("Diff and Int Calc.," pp 233, 239) that such discontinuity cannot occur in series proceeding by powers of a real variable, that in other cases it occurs only through the series becoming divergent at the point of discontinuity It is, however, an important question how far it would be allowable to avoid burdening an elementary exposition by complete precautions against the existence of anomalies like this, which would hardly have originally occurred to any one in that early stage

The book ends with a wider survey, including a clear and interesting account of Cauchy's theory of the radical points of a rational function The graphs of the cubic $x^3 + ax$, which are given as an illustration, would also form excellent and rapid examples of the Rankine-Maxwell method of graphical addition, applied to the separate graphs of x^3 and ax

J L

FOSSIL PLANTS AS TESTS OF CLIMATE

Fossil Plants as Tests of Climate, being the Sedgwick Prize Essay for the Year 1892 By A C Seward, M A, F G S, Lecturer in Botany in the University of Cambridge (London: C. J. Clay and Sons, Cambridge University Press, 1892.)

THIS admirable essay is really a digest of the opinions of the principal writers on fossil plants, so far as they throw light on geological climates, and a critical *résumé* of the subject up to date. It should be read by all who prefer to deduce the relative temperatures of various latitudes in the past from such solid data as assemblages of ferns, cycads, and conifers, the ancestors of living genera and species, rather than from utterly extinct belemnites, ammonites, and saurians, of whose habits little can ever be known, and which might have drifted far out of their temperature zones by warm and cold sea-currents

Perhaps if any criticism can be made, it is that too little has been said by the author as to what is known of the Mesozoic floras, which, if scanty, are extremely interesting In fact only the widely separated Palæozoic and Cenozoic floras are fully dealt with. Owing to the magnitude, difficulty, and freshness

of the problems presented by the former, they have received the larger share of attention and have ever attracted some of the most acute and philosophic of scientific workers But while the researches of such investigators as Williamson and Renault into the actual structures and affinities of the carboniferous plants have been rewarded with the most brilliant successes, attempts to speculate and theorize have only been productive of barren controversy All inferences as to the temperatures in which they flourished have merely been inductions from unknown data their affinities with existing plants are so remote that they can tell us of little beyond moist climates and spongy, marshy soils, liable to inundation, with possibly an atmosphere more highly charged with carbonic acid than at present But that neither the flora nor identical conditions were uniformly present over the whole land during the deposition of the carboniferous, becomes every year more apparent, and perhaps few would now maintain that fossil floras met with in widely-different latitudes must necessarily be contemporary because similar, or reject as impossible the correlation of the Glossopteris floras of the southern hemisphere simply because they are so dissimilar

Tertiary floras, however, have to be approached from almost totally different standpoints, for here minute investigations into vegetable structure can only exceptionally lead to important results On the other hand it may be possible to predicate the climate that any group among them would have required, with almost perfect accuracy. Allowing that even most closely-allied species may have had different habits, enough remain that are practically identical with living species These not only prove to us that in every land in our hemisphere the temperatures remained warmer throughout the Tertiary period than at present, but also that the temperatures were far from equable during Eocene time. Thus it is impossible to hesitate as to the evidence of the flora in the lower stages of our Eocene, which exhibits an abundance of planes, poplars, and alders and an absence of all approach to sub-tropical essences, nor as to that of the London Clay, with its tropical nipas, sabals, and a host of others almost indistinguishable from species existing at the present day There is scarcely need of the corroborative evidence of the Mollusca as to cooler seas in the Thanets, nor of tropical conditions in the large turtles, crocodiles, snakes, and nautili of Sheppey In fact, the temperature of the spots occupied by Reading, Bournemouth, or Mull at a particular stage of the Eocene could be predicated from the fossil floras almost as accurately as from living plants If the same cannot be said of the Arctic regions it is simply that the specimens brought home are, perhaps from the exigences of travel and inexperience of the collectors, for the most part so imperfectly preserved and fragmentary, that few of the determinations can carry the smallest weight. It may suit quidnuncs to accept indeterminable fragments as evidence of the growth of palms and cycads in the Greenland Eocene—it is time the Miocene age of these beds was relegated to the limbo of Coal-measure palms and yuccas—and to become excited over the presence of a sub-tropical flora within the Arctic circle; but as a fact it is doubtful whether anything has been discovered there which might not have grown in our own temperature, if slightly modified, a state of things which it is conceivable the damming back of the Arctic seas by the land connection which then existed between Europe and America, aided by an active Gulf Stream, might have brought about When we come to the Miocene, worked out as that of Switzerland was by Heer, or still more the Quaternary, with such data as those laboriously amassed by Clement Reid, the inferences as to climate are still more irresistible

As to evidence of the age of rocks, plants are less trustworthy, because they have neither been so perfectly studied nor are their zones as yet at all properly defined All we can say is that certain assemblages are found in association at the beginning of the Tertiary, and that changing temperatures have since compelled them not to disperse, but to migrate far and wide Fewer probably of the species are extinct than is generally supposed, and the primitive associations have held together perhaps to the present day, with many gaps from extinction and desertion and a large infusion of recruits through the ordinary causes of evolution, stimulated by the increase in browsing mammalia Whether, on the other hand, the marine deposit zones are really entitled to the weight attached to them as evidences of age, except locally, is not so clear They are usually the littoral deposits of a limited area, where some changes of level or current have apparently suddenly driven out the fauna and introduced new colonies more adapted to the changed conditions If we could follow the subsequent wanderings of these assemblages under the sea our faith in their sudden extinction and consequently in their chronological value might be greatly modified At all events, many of the less conspicuous groups of mollusca, when critically examined, prove to have surprisingly near relatives in distant seas at much later periods, and even at the present day

J STARKIE GARDNER

OUR BOOK SHELF

Pioneers of Science By Oliver Lodge, F R S (London and New York Macmillan and Co, 1893)

THIS book consists of eighteen lectures on the history and progress of astronomy, which were delivered by Dr Lodge in 1887 "The lectures having been found interesting," he thought it "*natural* to write them out in full and publish," and, although this can scarcely be considered a sufficient excuse, the intrinsic merits of the work are abundant justification for its existence. In Part I, "From Dusk to Daylight," the progress of astronomy from Copernicus to Newton is traced in a series of vivid pictures of Copernicus, Tycho Brahe, Kepler, Galileo, Descartes, and Newton; while Part II, "A Couple of Centuries' Progress," brings the history of gravitational astronomy from Newton down to the present time. In these latter lectures Roemer and Bradley are associated with the velocity of light and aberration, Legrange and Laplace with the solar system and the nebular hypothesis; Herschel with the motion of "fixed" stars; Bessel with the distances of stars, Adams and Leverrier with the discovery of Neptune, and Lord Kelvin and George H Darwin with tides. Dr Lodge has been able, by judiciously combining clear statements of scientific facts and laws with interesting personal details, to give his lectures all the charm of a romance. The book is an admirable introduction to the study of astronomy, and no better gift for a beginner could well be chosen, while to those to whom many of

its details are already familiar, the picturesque clearness with which they are presented will make their knowledge more real and more complete The standard of excellence maintained in the lectures makes distinction difficult and invidious, or we would distinguish the lectures on Newton and those on tides as models of what such popular scientific expositions should be The book is copiously, and, on the whole, well illustrated, but some of the illustrations—notably those of clusters and nebulæ—are very familiar and somewhat out of date A curious mistake occurs on page 291, where a well-known drawing of a comet appears as an "old drawing of the Andromeda nebula" The illustration on page 326, showing the paths of Uranus and Neptune and their relative positions from 1781 to 1840, and professing "to illustrate the *direction* of their *mutual* perturbing forces," is partly misleading, but in introducing this Dr Lodge has erred in good company, for the diagram, originally due to Dr. Houghton, appears in many of our recent astronomical text-books A 'I

Electric Lighting and Power Distribution Part I By W Perren Maycock, M I E E (London. Whittaker and Co, 1892)

THIS cheap and useful little text-book has been written for the author's junior students, as he is of opinion that no trustworthy elementary work on the subject is to be obtained The scope of the work has been limited to the syllabus of the ordinary grade examination of the City and Guilds of London Institute We find, however, much information on subjects not usually found in other manuals The book is freely illustrated, and the descriptions are clear

It is very important for the junior student to understand clearly what is meant by a line of force, and to grasp the fact that lines of force are only *assumed* to exist, because, by such an assumption it is possible to explain many, otherwise inexplicable, phenomena On page 47 we find the following statement —"The power which any magnet possesses, of picking up pieces of iron, and of acting upon another magnet, depends upon the existence of lines of magnetic force" This quotation is vague, a junior student might easily imagine that the lines of force really existed, whereas they are purely assumptions, to elucidate the phenomena of magnetic attraction The illustrations of simple bar magnets, solenoids, and electro-magnets, in which the lines of force are delineated, should have the assumed directions of the lines of force clearly shown by arrow-heads. This might be done with advantage in Figs. 17 to 20

Chapter IV deals with induction of currents, electromagnetic induction, Faraday's Law, and concludes with a clear description of magneto-motive force, magnetic resistance, magnetizing force, induction and permeability These latter are very difficult for a junior student to understand thoroughly, and the author should have devoted more space to the discussion of these important points in dynamo construction One particularly good feature in this text-book is the large number of questions arranged at the end of each chapter These are well suited to test the knowledge of a student Chapter V deals generally with electrical testing, measuring instruments used in installations, and meters for measuring the current, such as Teague's, Elihu Thomson's, and the Wright-Ferranti Chapter VI concludes the book, describing the principle of the dynamo, different types of machines, and the construction of the various parts.

Taken as a whole this book attempts too much. The matter described has suffered considerably by condensation, a serious thing where junior students are concerned. Most of the illustrations are good, some are indistinct, and Fig. 98 is decidedly wrong, showing the brushes set for one direction of rotation, and the arrow indicating the reverse.

On the other hand the sequence of matter is good, and a student should learn much from the work. The author takes great pains to describe clearly the many units involved, particularly the applications of Ohm's law The book would last much longer in the hands of the average student if the present paper binding were replaced by something stronger

The Naturalist on the River Amazons. By Henry Walter Bates, F R.S With a memoir of the author by Edward Clodd Reprint of the Unabridged Edition With Map and Numerous Illustrations (London John Murray, 1892)

THIS work is so well known, and has long held so high a place among scientific books of travel, that it is unnecessary to do more than note the appearance of a new edition. It is clearly printed on good paper, and the illustrations are well reproduced The introductory memoir by Mr Clodd is a most welcome record of the main facts of Mr Bates's career The materials for this interesting sketch were enriched by letters placed at the author's disposal by Sir Joseph Hooker and Mr Francis Darwin An excellent portrait of Mr Bates is included in the volume

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

A Proposed Handbook of the British Marine Fauna

SUCH a handbook as Prof Herdman suggests is so much wanted that many naturalists must from time to time have felt tempted to essay it But the difficulties are very formidable Prof Herdman seems to contemplate the preparation of such a work mainly as a labour of compilation. But the groups where compilation would nearly suffice are just those where the handbook is least required On the other hand, such a group as the Amphipoda, in spite of Canon Norman and Mr Stebbing's many papers, is still in great need of revision, It was only the other day that Canon Norman opened our eyes to our rich fauna of Mysidæ, before which time no search among published records would have told us anything worth the having, we are in just the same position as to our British Cumacea, until Canon Norman again reveals the treasures of his cabinet, our Pycnogons are almost as little known In every one of these groups, and in many others like them, the preparation of a hand-list would need the experience of a specialist, just as much as the Tunicata would require Prof Herdman's own special knowledge The area to be embraced is another difficulty Prof Herdman proposes to take the British area as defined by "Canon Norman's" B.A Committee in 1887, on which he himself served But the committee's report was repudiated by Canon Norman himself, who afterwards suggested a wider "British area," whose boundaries I fancied had since been recognized as more suitable by everybody However the British area be defined, there will long remain a difficulty in the numerous forms not yet recorded from within it, but which are likely, or certain, to turn up when sought for Such things as the parasitic and other Crustacea described of late years by Giard and his pupils from Wimereux form a case in point I am inclined to think that to make in the first instance a hand-list of the whole fauna of the North Atlantic basin would be not a bit more difficult, but in some respects easier, than to restrict the list to the British area alone. That it would be incomparably more useful is certain. It would make a book not more than three times (perhaps little more than twice) as big as Carus's "Fauna Mediterranea." And it would be a very important step towards that new *systema naturæ* of which the Germans are already beginning to talk, and which it is high time were begun

But Prof. Herdman both asks discussion of his plan, and also invites criticism on his execution of it Take his very first illustrative genus, which he tabulates as follows:—

ANTENNULARIA.—Stems simple or branched, pinnæ verticillate; nematophores along the stems, gonothecæ axillary, unilateral.

A antennina, L, stems clustered, usually simple, hydrothecæ separated by 2 joints 6 to 9 in high. Gen. distr deep w

A ramosa, Lamk, stems single, usually branched, hydrothecæ separated by 1 joint only 6 to 9 in. high Gen. distr deep w

Now there are *no* nematophores along the stem, but only on the pinnæ, *A ramosa* may sometimes grow up unbranched, but I for one never saw it so, and *A antennina* is always simple, save by the rarest individual abnormality, the dimensions are quite inaccurate, for we have *A antennina* here of all sizes up to 24 inches high. The distribution given is too vague In the report of the B A Committee, which Prof Herdman goes by, deep water is defined as that below 100 fathoms, but these two are not deep water species, either in that or any other common use of the phrase The authorities are very loosely given *A. antennina*, L, should be (L), and if the bracketed authority, *i e* the original user of the specific name, is to be the one quoted, then for *A ramosa*, I think Lamk should give place to (Lamx) And why is the authority for the genus left out altogether?

Moreover, even if these definitions were verbally accurate so far as they go, they would only suffice to exclude one another, with no reference to other non-British species They are rather definitions of groups of species or sub-genera, than of these two particular forms It would not matter very much, perhaps, in this case, where other species are not likely to turn up upon our coasts, but such definitions, drawn with reference only to known British forms, would soon lead to hopeless confusion in the case of less known groups D'ARCY W THOMPSON

On an Abnormality in the Veins of the Rabbit

AMONGST a number of rabbits dissected in my laboratory last term, one specimen exhibited a peculiarity in the venous system which is especially interesting in connection with Hochstetter's and Macalister's accounts of the development of the veins Unfortunately the specimen had been too far dissected before the abnormality was noticed to follow out every detail

The blood from the hinder extremities, urinogenital organs, and abdominal walls, passed into a large vessel having the position and relations of a postcaval posteriorly Instead, however, of passing through the dorsal border of the liver to penetrate the diaphragm, it was seen at the anterior part of the abdomen to correspond to the azygos, receiving the superior intercostal veins, and opening into the right precaval. This vessel evidently, then, corresponded to the persistent right posterior cardinal The portal system was apparently normal, and the hepatic veins opened into a postcaval, which extended through the diaphragm to the heart in the usual manner

Thus the independently-formed section of the postcaval (*Leberabschnitt*) had taken on no connection with the part developed from the cardinals (*Urnierenabschnitt*), but had remained as a separate vein, bringing back the blood from the alimentary organs (and ? diaphragm) only.

I have not thought it necessary to do more than mention these facts, as the whole question has recently been fully discussed by Dr A Robinson ("Abnormalities of the Venous System and their relation to the Development of Veins," "Studies in Anatomy from the Anatomical Department of the Owens College," vol 1 p 197, Manchester, 1891). The above case, however, supports the view that the renal veins are direct tributaries of the right cardinal, and not of the postcaval; while the reverse conclusion is derived from Dr Robinson's observations. Difficulties of Pliocene Geology.

YOU were good enough to print a letter from me a week or two ago, in which I called attention to some of the difficulties in explaining the distribution of the so-called Pliocene beds. I should like to prosecute the subject a little farther

The geographical distribution of the mastodon is assuredly one of the greatest paradoxes in natural science.

As is well known, it occurs both in North and South America, and on both sides of the Rocky Mountains and the Andes. It has not occurred, however, so far as I know, north of the great lakes in the east, nor of Oregon in the west, nor has it ever been reported from Alaska, where mammoth remains are so abundant. I do not know any evidence that it has been found anywhere in Asia, north of the Himalayas, neither in China, nor Manchuria, nor Mongolia, nor Turkestan, nor in Siberia, nor has it occurred in European Russia, except close to the Black Sea, nor in Poland, nor in Scandinavia, nor in North Germany

In the Old World its zone of distribution extended from India to the Pyrenees, including the Mediterranean borders, the valleys of the Danube, and the Middle Rhine, Eastern England, and perhaps Iceland, whence some teeth are said to have been sent to the royal collection at Copenhagen This distribution of a very highly specialized beast is certainly most extraordinary Granted that the mastodons of Western Europe and those of America are slightly different, the difference is so slight that, as Falconer says, Cuvier treated them as the same species, and they cannot have been very long isolated Yet how are we to explain the facts, and do justice to the widespread view that the ocean areas are very old?

It seems to me as clear as anything can be that when the mastodon was distributed over Western Europe and America, there must have been a land communication between the two areas, and I cannot see how, with the facts before us, we can escape the conclusion that this connection must have been across either the Atlantic or the Pacific, not in high but in low latitudes, perhaps across both

The mastodon is not the only animal which points the same lesson The machairodus, a very highly specialized feline, has been found both in the Old and the New World, but did not inhabit the great palæarctic province of Europasia, east of the Rhine, nor America north of the great lakes The American jaguar, a mere variety of the Old World leopard, is another animal with the same abnormal distribution, so are the American and the Old World tapirs.

Now this connection between the Old and the New World cannot, so far as we can judge, have been in high latitudes, for the forms in question have not occurred in high latitudes. If the connection had been across the Northern Pacific, we should have had some remains of these animals in Japan, where more than one fossil elephant has occurred, or in the Sandwich islands, which are, to all appearances, a very old land surface

The connection must, therefore, if it was across the Pacific, have been across its more equatorial part It seems similarly to follow from the absence of these animals in the high latitudes of America and Europe, save the doubtful case of Iceland, that in the case of the Atlantic also the land bridge must have been further south, and perhaps where the Atlantic islands still remain One more inference If there was a penannular or circular belt of land about the earth in the tropical or subtropical zone over which these beasts could travel, it would possibly account for the tertiary climate of high latitudes having been a warm one, as we know it was A zone of land in the tropics would act as a furnace, whose heat would be widely distributed by the ocean currents in contact with it

The views here urged, it will be said, are like those of the advocates of a Miocene Atlantis They are in essence very different, and meant to explain a very different phenomenon, namely the aberrant and abnormal distribution of the mastodon and its companions. The mention of the Miocene Atlantis, however, suggests another and more critical difficulty in explaining the Pliocene beds, but this must be postponed to another letter HENRY H HOWORTH

Earthquake Shocks.

A SERIES of slight earthquake shocks have lately occurred in this district, viz. January 3, 2.15 p.m. at Severn Junction (E.J.L.) January 4, 11 a.m, Itton Court, Chepstow (a heavy plant stag in a greenhouse was seen to move four times by Mr J. Curr and the Rev. N. S. Barthropp), January 5, between 2 and 3 p m, and again on the 6th (a little earlier), Llanthony Monastery (a rumbling noise on the Black Mountains near the monastery Mr. P. E. Hill); January 14, 6 55 p m., a shock lasting more than a second, Bigswear House, Coleford, Mr. J V. Newbery (Mr. Newbery has had experience of earthquakes, from a long residence in Japan) E. J. LOWE.

Shirenewton Hall, Chepstow.

The Weather of Summer.

I REGRET to find that, in making a quotation at the end of my letter last week (p. 246), I erred in supposing Mr. Symons to be the writer. I beg to apologize for the slip. A B M.

ON THE ORIGIN OF THE ELECTRIC NERVES IN THE TORPEDO, GYMNOTUS, MORMYRUS AND MALAPTERURUS

THE subject of this communication may seem remote and uninteresting, but it will not be difficult to show that questions of the highest importance for physiology, anatomy, and the Darwinian theory are closely related to those touching the structure of the electric organs of certain fishes and the laws of their functions

The fact that the body of an animal should become a complete electrical apparatus acting at the will of its owner induces us to inquire how this extraordinary result has been attained, that is, to investigate the origin of the electric organs of fishes, and the manner in which the animal throws them into action We shall see that in pursuing both lines of enquiry we open far-reaching views into regions as yet unknown

According to the present state of our knowledge there can be no doubt that most of the electric organs hitherto discovered are of muscular origin It is not my intention to dwell on this transformation of muscular tissue, but it may nevertheless prove interesting to cite an example of the completeness with which such transformation can take place, I refer to the Mormyrus—the so-called pike of the Nile—a fish which has only of late been sufficiently known to possess electric power A transverse section of the tail of any ordinary fish shows scarcely anything more than the vertebral column, muscles and their tendons, attached to the bones. On the other hand, a transverse section of the tail of Mormyrus (Fig 1) shows no conspicuous muscles, but in place of them electric tissue filling up the entire space occupied by muscles in ordinary fishes. Of the muscular apparatus there is nothing left except the longitudinal tendons passing outside the electric organs from muscles placed anteriorly. If these tendons were cut across the Mormyrus would be unable to move its tail.

Omitting the complicated arrangement of histological elements in this modified muscular tissue in the different electrical fishes—which could not be sufficiently explained without a large number of illustrations—it may be sufficient to state that a kind of swelling loosens the molecular elements of the muscles and allows them to be settled again in a very regular but quite new form.

The well-known electric eel of America, *Gymnotus electricus*, has only the external shape of an eel, and is in reality a very short fish, carrying very powerful electric organs in a long tail springing from a very short rump A transverse section of the tail shows that a part of the muscle is changed into electric organs, while another remains unchanged

In the different kinds of electric skates—Torpedinidæ—the electric organs are developed from muscles, which originally belong to the branchial arches and the arch of the lower jaw

When we look to the nerve apparatus which enables the fish to throw the electric organs into action by a voluntary impulse, we find in every case wonderfully developed ganglion cells from which the impulse is transmitted directly to the electric batteries Such a coincidence certainly cannot be the result of mere chance But beyond the invariable presence of large ganglion cells as the starting points of electric nerve fibres there is very little uniformity in the arrangement of these elements in the different sorts of electrical fishes, on the contrary, there are most remarkable and striking differences not only in the position but also in the number and in the appearance of these nerve centres It is to be hoped therefore, that some important views regarding the character and functions of ganglion cells in general may be suggested by their study

In the Torpedo the electric ganglion cells—being in vast numbers—form a bean-shaped mass in the medulla constituting the well-known electric lobe It represents modified motor centres of the vagus nerve; anteriorly it is covered by the cerebellum, but emerging from beneath that organ, the lobe increases rapidly where the largest electric nerve leaves the medulla. Lower down its size again diminishes, where it gives rise to the fourth electric nerve and terminates quite free in a blunt point on each side. On counting the ganglion cells in a complete series of sections one finds the number to be about 54,000—a number that can be found to nearly correspond with the fibres in the electric nerves that arise from them. A transverse section of the medulla, close to the spot where the roots of the electric nerves are gathering, shows the so-called axis cylinder processes of the cells entering the roots to form the nerves. This is seen in Fig 2—a photogram taken from nature like all the other illustrations of this paper

FIG 1—Transverse section of the tail of *Mormyrus cyprinoides*

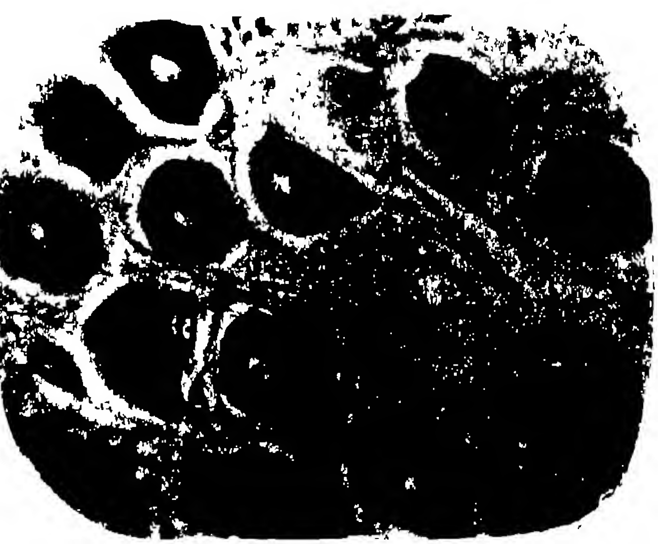

FIG 2—Ganglion cells from roots of electric nerves of Torpedo

Even the first and smallest of the electric nerves shows a great number of nerve fibres collected into bundles which on transverse section appear as if perforated by numerous small openings—each apparent aperture being a nerve fibre I counted about 8039 fibres in the first electric nerve, in the second or largest about 23,770, in all four nerves about 58,318 fibres This total exceeds that of the ganglion cells by at least 4000, but the disparity of number is probably to be accounted for by the impossibility of getting an exact total from a series of sections where the cells are very often dragged away by the knife

The ganglion cells of the Gymnotus, or electric eel, are disposed in a different manner Behind a short portion at the anterior end of the spinal cord where ordinary cells are found, the grey substance contains large rounded ganglion cells, the most anterior of them forming a semicircle around the central canal of the cord Since these first cells extend in front of the most anterior electric nerves, a transverse section of this region shows no axis cylinders leaving the grey substance, all being directed downwards to the gathering place of the first electric nerve roots, and therefore must be cut off. If, however, a transverse section be made in the middle portion of the cord the whole grey matter is seen to be packed with electric cells and their axis cylinders are seen passing very straight and undivided to join the electric nerve roots at once. The other processes of the cells are so pale and fine that it is impossible to recognize them sufficiently well in a complete section. Since the electric batteries extend along both sides of the tail to its very end, the electric nerves and their ganglionic centres have a similar extension. The electric cells form a continuous column in the spinal cord, but it is very slender, therefore, notwithstanding the great longitudinal extent of the electric centre, the number of cells is not so very great. I estimated the total number of cells to be about 60,000—not many more than the estimated number in the Torpedo.

The genus Mormyrus, whose electric power was doubted until quite recently, resembles the Gymnotus in the structural arrangement of its electric apparatus. I was fortunate enough to find the ganglion cells for the electric nerves in the spinal cord, where the tail is endowed with the electric batteries, as seen in Fig 1 The cells are very soft, and must be very carefully preserved to show all their details Their regular undivided axis cylinders leave the cord-like motor roots, and form a sort of plexus before leaving the vertebral canal. It is to be considered as a very important fact, that broad processes of the cells regularly intercommunicate on so large a scale that their union into a complete system for simultaneous action cannot be doubted

Fig 3 shows such cells in the grey substance of the spinal cord; the intercommunicating processes can be seen much more distinctly in the microscopic slide and even in a photogram, than they appear in that figure.

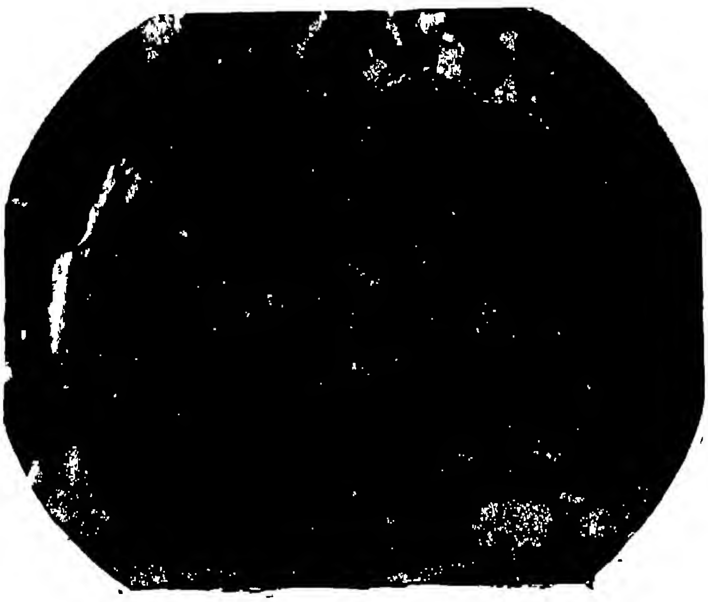

FIG 3.—Communicating Electric Cells in the Spinal Cord of Mormyrus

The axis cylinder of each cell being a well-defined undivided process, the intercommunicating processes must be regarded as protoplasmic in the sense expressed by Deiters Their general intercommunication cannot have any other significance than to insure equality of action in giving the impulse to the electric batteries If that statement be admitted *the protoplasmic processes of the cells must have a conducting function* If that be true in the Mormyrus there is no reason whatever why it should be otherwise in other vertebrates Yet Golgi maintains that the protoplasmic processes of nerve cells are to be regarded as having a simply nutritive and therefore a non-nervous function

There is another most remarkable fact in the organization of the Mormyrus having reference to the combined action of the electric organs on both sides The upper as well as the lower electric nerves form a decussation outside the vertebral canal resembling the chiasma of the optic nerves I am not acquainted with any other instance of motor nerves crossing the median plane to the other side of the body outside the cerebrospinal axis In all other cases they are outside the brain and the spinal cord confined to their own side of the body to insure the isolated action of each muscle or group of muscles on that side It is therefore stated that in changing the motor into an electric function these nerves at the same time became liberated from the strict rules of their predecessors. Certainly the case of Mormyrus gives a very good idea of the extraordinary power of adaptation to function with which Nature is endowed, but who can say how this particular anatomical arrangement could come about by gradual variation? I consider this difficulty far greater than that relating to the first development of electric organs in general which is so frequently the subject of reference.

Since the celebrated investigations of Prof E. du Bois-Reymond have shown that the function of the muscular system is intimately associated with electric currents it is permissible to take them into account where muscle and their derivatives are under consideration.

I have shown elsewhere that most of the electric fishes are liable to a degeneration of the muscular system, seemingly caused—in part, at all events—by a certain lazy mode of life (disuse of organs). We therefore find along with fully developed electric tissue in the Gymnotus, nests of muscles which have not arrived at perfection. In the Mormyrus degenerating muscles in the forepart of the electric organ suggest the impression that the process of transformation is still going on. Still more is this the case in the common Raja.

Moreover, we know that the peculiar degeneration of muscular tissue into electric tissue destroys the contractile power of the muscles, but does not interfere with their

electromotor properties, on the contrary the loosened and differently arranged elements of the changed muscles are more capable of producing electric currents In that

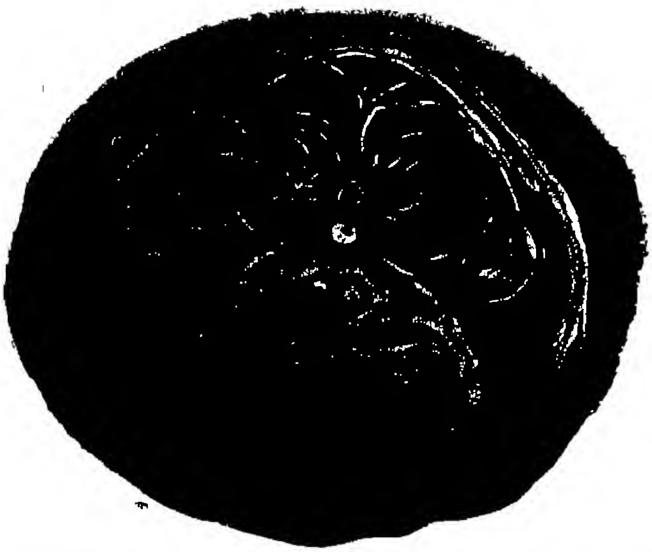

FIG. 4—Transverse section through the body of Malapterurus with a parasite in the electric organ

state of development which has still quite an occasional character, it seems only necessary to assume that under certain favourable circumstances the fish while trying to catch a prey or to defend itself against an enemy in the sudden excitement becomes aware of its electric power hitherto unknown to itself. On perceiving the advantage of the electric power in the struggle of life the fish might begin to use it regularly and to develop it gradually to perfection in its descendants, just as a man might one day perceive that he is endowed with the power of hypnotism, consequently learns to use it and gradually improves it

But now it is necessary to consider also the electric Shadfish of the Nile, the *Malapterurus electricus*, a powerful fish of very peculiar structure, which places it in quite a different category from the electric fishes already mentioned. A transverse section of the whole fish (Fig 4) shows the difference at once The body of the animal is enveloped in a very thick electric skin, constituting one electric organ. Muscular tissue is nowhere deficient, other histological elements must therefore have furnished the material for the electric plates, which are packed very close in lozenge-shaped compartments of the skin

In my opinion the plates are nothing else than modified cells of the cutaneous glands which are plentiful in the remainder of the skin The precise proof of that statement ought to be furnished by a complete investigation of the development of the animal, which as yet is quite unknown. But the differences between the two kinds of electric organs are so great that we are surely entitled to separate the *muscular* from the *cutaneous* electric organs.

Assuming that the origin of these cutaneous batteries differs from those developed from muscle, we cannot wonder that their functions also differ in most important points. The electric current passes through the body in a direction the opposite of that in other electric fishes. There are *only two* electric nerve fibres, one on each side, which divide and subdivide until they give off more than two million branches. We shall see that these two nerve fibres are not true axis cylinder processes of ganglion cells Before making a more detailed reference to these interesting elements it may not be amiss to point out in the section shown in Fig 4 the existence of an intruder, a specimen of the so-called *Filaria piscium*, which had taken up its abode in the electric organ itself This proves that animals can become accustomed to strong electric currents without receiving injury, and it suggests that the immunity of electric fishes against their own currents and that of their young *in utero* (Torpedo) is a faculty acquired by gradual training

The construction of the single electric nerve fibre in Malapterurus resembles to a surprising extent that of an electric cable on a minute scale We see the tiny nerve fibre like the central wire of the cable surrounded by a little non-conducting material and held *in situ* by a sort of network, the whole being enveloped in an enormous mass of connective tissue sheaths just like a cable protected externally by numerous layers of strong material. Fig 5 shows a transverse section of the central part only to render the details of the round fibre and supporting network more distinct If we follow this single fibre inwards to its origin in the central nervous system we are led to *a single ganglion cell* from which the single fibre arises. There is one cell on each side of the cord, therefore just two cells in all, whereas in Mormyrus, which has the smallest number of electric cells in the fishes with electric organs of muscular origin, the cells must be estimated at more than 1500 The position of the two cells in the spinal cord of Malapterurus reminds one of Clarke's column in the cord of higher vertebrates where the cells differ in certain particulars from the motor cells As already stated there is only one cell on each side, but

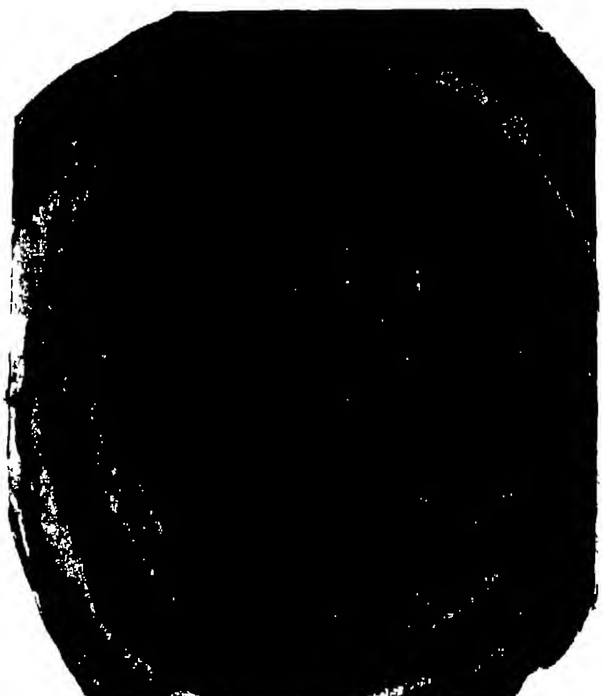

FIG. 5.—Transverse section of the central part of the electric nerve of Malapterurus.

that is a giant of its race. There is no real axis cylinder arising from the cell, but in place of it branched protoplasmic processes join and form a kind of perforated

plate beneath the cell, from which the nerve fibre starts with a broad base (Fig 6) I consider this a chief point of difference between this peculiar cell and all the other afore-mentioned cells of a motor character Fig 6 gives a good idea of this magnificent histological specimen with its elegant nucleus showing its network and its nucleolus on one side

Reviewing from a physiological standpoint the several facts stated above, we must feel convinced that the peculiar ganglion cells which are invariably found in relation to electric organs must play an essential part in bringing the electric organ into action In my opinion that is tantamount to proof that other ganglion cells must be essential for sending nerve impulses to peripheral organs, and that the idea lately suggested by Nansen that ganglion cells have only a trophic influence on nerve tissue cannot be reasonably maintained in the face of these and similar facts I may here refer to the well known peculiar ganglion cells found in the motor region of the brain of higher animals, including man Betz, who discovered them, searched for them for the purpose of stating anatomically the laws of localization found by Prof Hitzig and myself

It may not be out of place to adduce here another piece of evidence taken from the department of pathology. My friend and collaborator Hitzig has lately published the case of a man who died from tetanic cramp of the head He observed that in the ganglion cells of the motor centre of the fifth nerve presiding the affected muscles there was a very singular change to be observed *in these cells only* It appears that the bacteria of tetanus caused a granular decomposition of the protoplasm in the cells, which led to a further state of degeneration characterized by the appearance of large holes, while the other ganglion cells and the remainder of the organ appeared quite healthy I am convinced the case shows that the cramps in the combined muscles resulted from the irritation and gradual disorganization of the ganglion cells

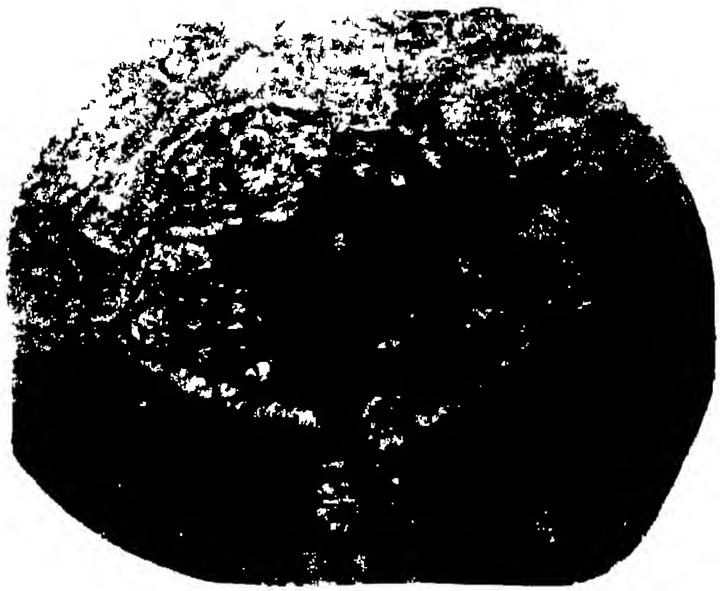

Fig 6 —The right giant ganglion cell with the origin of its electric nerve from spinal cord of Malapterurus

The above statements may suffice to show that the electric fishes and their nervous elements are really not such outsiders in science, and that the observations made on them should be brought into comparison and correspondence with those gathered from other sources Indeed the histological elements in their organs are so instructive, that I would strongly recommend that the conclusions deducible from their study should be employed in maintaining well-founded former notions regarding the organization of the nervous system in vertebrates against certain revolutionary ideas of some modern authors GUSTAV FRITSCH

Physiological Institute, University of Berlin

AUSTRALIAN TRAVELS[1]

On opening this work, one is at once struck by the beauty of the illustrations, particularly those of the New Zealand Alps. The double-page plate opposite p 248, drawn from a photograph taken by the author, is especially worthy of remark For effect this view may well compare with some of the most picturesque parts of Switzerland. Some of the photographs, however, have a familiar appearance to the travelled reader, one recognizes in the beautiful picture "Off the West Coast of Ceylon" (p. 300) an old friend, none the less worthy of reproduction.

[1] "Australische Reise," by R von Lendenfeld, pp 325, with Illustrations. (Innsbruch Wagner, 1892)

The work makes no pretensions to a virgin freshness its professed object being to gather together the already published observations of the author, and to present them in a popular form This it does very successfully, though the English reader could have dispensed with a good deal of the very apparent "padding" Thus the first twenty pages of this book of travel are devoted to the history of Australia, and remind one of Coghlan's opening chapter in the "Wealth and Progress of New South Wales" the next twelve pages on gold differ from Coghlan's second chapter, particularly in giving greater prominence to Count Strzelezki's discovery, and one regrets that no mention is made of James McBrian, who certainly has prior claims The author is candid in his criticisms and condemns both the theatres and University of Sydney, as being, from the German standpoint, decidedly bad On p 34 we come to a "Journey into New South Wales," and here commences an interesting medley of natural history, traveller's tales, and geographical investigation In this vacation ramble Von Lendenfeld claims to have discovered the culminating point of the Australian continent in Mount Townsend, to which he assigns (by aneroid) the height of 2241 metres The doggerel verse on p 82, in which a red sunset is taken to indicate approaching rain, must be wrong in its meteorology, so at least it proved, a red sunset being followed, much to Lendenfeld's surprise, by a fine day It is satisfactory to find that the signs of the weather are not inverted at the Antipodes

The author's familiarity with glaciers and ice-action in Europe served him in good stead in the southern hemisphere Several interesting pages are devoted to his discovery of the former existence of glaciers in the Australian Alps, though there seem to have been contemporaries in this matter, for while Von Lendenfeld's observations proved the existence of *moutonnéed* and striated surfaces down to a level of 1500 metres above the sea—Mr James Stirling claimed to have found signs of ice-action at lower levels still, as in the neighbourhood of Omao, where they occur at 800 metres above sea-level. The historical conscience is strong in the author, or he would scarcely have troubled to recall the

fact, that when his communication on the discovery of glacial markings was read before the Geological Society of London, it was received with scepticism by Prof Bonney (and, let us add, though the author does not, by Dr Blandford also) On turning to the *Journal* of the Society we find that Prof Bonney considered the observations then adduced by Von Lendenfeld as insufficient to establish his conclusions, and in this opinion we fancy most geologists will be inclined to agree with him That the conclusions were right after all is a different matter It is to be regretted that even in this, his latest published summary, Von Lendenfeld does not always supply us with facts on which we can base an independent judgment The personal opinion of an observer, however skilled, can be no sufficient substitute for these A single instance will suffice An important joint expedition was undertaken by the author and Mr Stirling to examine into the accuracy of the latter's statements as to the downward extension of the ice After several pages of interesting traveller's gossip we reach the result in words much to the following effect —"After three-quarters of an hour's ride in the valley bottom we reached an old moraine, which we investigated closely A dam 35 metres high and 200 broad composed of various (*verschieden*) great blocks of rocks with sharp angles stretched across the valley A brook flowed through the middle We are here at a height of from 900 to 1000 metres, and since it is a veritable moraine Stirling is right and our dispute is ended"

We will not offend the susceptibilities of the author by questioning whether this is really a moraine probably it is, but no convincing proof of the fact appears in the description One would like to know whether other signs of ice-action were observed in the immediate neighbourhood, in what respects the fragments differed from each other and from those of the adjacent valley slopes, and especially what evidence existed to show that they had been carried down the valley, and how far they are removed from their source This information could have been conveyed in a few words, and would have been welcomed by inquiring minds, who now may wonder whether after all this dam could by any chance be merely the remains of an ancient landslip New Zealand is introduced to us on p 161, and after a short historical account we pass on to the New Zealand Alps and fjords. With regard to the latter the author stoutly maintains their glacial origin one of his chief arguments resting on their great epth as compared with the sea into which they open They are apparently submerged rock basins, but although the author may be right in his contention that they are not merely moraine-dammed valleys, yet he altogether overlooks another more probable explanation, depending on unequal subsidence submergence of the land has certainly taken place, and one has only to concede that the central mountain masses have sunk to a greater extent than the adjacent sea-floor to understand how the previously existing valleys would be converted into fjords The greatest depth of Milford Sound is 360 metres, and one must travel (so our author tells us) at least 100 kilometres from the coast before this depth is reached at sea, now as the watershed is distant only 30 kilometres from the coast, it is at least as probable, considering the gradient, that we have to do here with differential movements of the land, as with locally concentrated erosive action.

An ingenious attempt to explain the last glacial episode leads to several bold generalizations. The author commences with the assertion that the whole of the southern hemisphere is at present much more severely glaciated than the northern, indeed he goes so far as to state that the northern hemisphere in the middle of the ice period was not much more severely glaciated than the southern is now. Since the mean temperature of the southern is not lower than that of the northern hemisphere the reason for its excessive glaciation must lie in a more uniform climate and a damper atmosphere, and these again are a direct consequence of the greater extent of the oceanic surface

Let us now suppose the sea-level in the northern hemisphere to rise 100 metres, the lowlands will become submerged (as during the last glacial episode they apparently were) the climatal conditions will then approach those now prevailing in the southern hemisphere, and excessive glaciation will result

But in the southern hemisphere also, the ice was formerly of much greater extent, and this is not susceptible of the same explanation, since a depression of the land would not greatly affect the existing climate What, however, would be the effect of a depression of the sea level? The submarine slopes of most of the land in the southern hemisphere are so steep that the present distribution of land and sea would not be largely modified, though the latter should sink 300 metres, on the other hand, the increase in the height of mountains (300 metres) would lead to a descent of the snow line, the growth of snow fields, and a corresponding enlargement of glaciers Thus the glacial episode in the northern hemisphere might be attributed to an elevation of the sea-level, that in the southern to its depression and these changes of level may have been produced by a bodily movement of the ocean waters from one hemisphere to the other, a result itself possibly due to a shifting of the centre of gravity of the earth The author does not explain how to shift the centre of gravity of the earth

We notice that the author speaks with disrespect of the maps of the Tasman glacier by Mr W S Green, stating that they are nothing like so good as Von Haast's, since however, later explorers prefer them to Von Lendenfeld's own, it would appear that we have here a descending scale of excellence

After pointing out the failure of Mr Green to reach the actual summit of Mount Cook, the author gives a glowing account of a successful ascent of his own, not of Mount Cook however, but of the Hochstetter Dome! He therefore claims to be the first who has set foot on the top of a high mountain in New Zealand We offer him our congratulations

In commenting on the author's style, which in its lucidity is far more English than German, we must offer a serious protest against his manner of using what he terms our "transcendentally intense adjective" Bob Acres' remark that, "The best terms will grow obsolete Damns have had their day," does not appear to apply to Australia, where, to judge from our author, they flourish along with other survivors of a Mesozoic age

AMERICAN FORESTRY[1]

COMPETENT English authorities on forestry are so rare that no apology is needed for presenting some extracts from a translation from the German, of an important paper by Sir D Brandis on American forestry This is in continuation of a similar translation which appeared about a year ago in the columns of NATURE (vol xliv p 60)

Upwards of 1,000,000 acres of forest are required for the annual supply of wooden sleepers for European railways These forests are properly managed so as to yield a steady return, whilst nothing of the kind can be said of American forests This explains why German foresters are interested in watching the progress of forest destruction in America, where it is now merely a question of ten or

[1] "The Silva of North America" By C S Sergent, vols i-iv (Boston and New York Houghton, Mifflin and Co, 1891-92) Notes on the above by Sir D. Brandis, K C.I E, F R S, in *Zeitschrift für Forst und Jagdwesen*, October, 1892

fifteen years before a timber famine must occur, which will greatly enhance the value of European forests.

Brandis explains the present lamentable state of affairs in the United States, as follows.—The Timber Culture Act, which was in force in certain of the States, provided that settlers should plant up with trees one quarter of the area allotted to them, and it was thus hoped to obtain forests in the treeless regions between the Rocky Mountains and the Mississippi river. Large tracts of land have been occupied under this Act, but very little progress has been made in afforestation. It is not difficult in the Republic for people to neglect engagements they have made with the State. It has been recognized for some time past that this law has been practically of little use, and it was therefore abrogated in March, 1891. The law abrogating it, in section 24, empowered the President to demarcate and reserve certain tracts of State forest. Great hopes were therefore entertained, and soon afterwards a proclamation was issued largely extending the Yellowstone Park, in Montana, on the borders of Canada.

This measure had been strongly supported for some time past by the American Forestry Association. The Park is a mountain forest tract on the water-parting between the Rivers Columbia and Missouri, and its preservation and proper management is of immense importance. In October, 1891, the extensive forest tract in Colorado in the Rocky Mountains, in which several large tributaries of the Colorado river have their rise, and containing 1,365,000 acres, was proclaimed as the White River Forest Reserve. It was also expected that a portion of the western slopes of the Sierra Nevada, bordering on the Yosemite National Park, and other localities where the *Sequoia gigantea* flourishes, would be proclaimed as State reserves. These two national parks were previously reserved under older laws. The numerous intelligent friends of forestry in America confidently expected that a beginning would now be made in the demarcation of extensive State forest reserves, and in their scientific management.

The most recent news from America, however, has thoroughly upset these expectations. A Bill has been introduced into Congress, to hand over most of the Yellowstone forest reserve to a railway company. It is considered certain that this Bill will pass the Lower House, and it is not expected that the Senate will refuse to sanction it. Wood merchants, mining speculators, and sheep owners are vigorously agitating against the proposed reserve in the Sierra Nevada, and it is feared that their agitation will carry the day.

The American Forestry Association, which held its tenth annual meeting last January, has "memorialized" the President that instead of making a few reserves here and there, he should proclaim the reservation of all State forests still left to the Union, and arrange for their proper management. Friends of the forest are numerous in America, and insight into the essential necessity of forest protection is spreading, owing to the numbers of Americans who travel in Europe, but in a land where the dollar rules, and where an individual who will not recognize its authority is considered a fool, any steady progress towards State forest management cannot be expected.

Bernhard Fernow, the chief of the Forestry Branch of the Ministry of Agriculture at Washington, still hopes for action in this direction on the part of Congress and the State Executive. At the last meeting of the Forestry Association he rightly urged that æsthetic and sentimental grounds for improving American forests must be left entirely in the background. Only where important material interests are concerned, such as securing a continuous supply of wood, or a supply of water, or climatic considerations, should the State limit the freedom of its citizens in dealing with forests. If, however, for urgent reasons of public utility, it should be necessary to reserve a forest, the State should not be contented with merely demarcating and protecting it, but should introduce scientific management, so that the neighbouring populations may be able to utilize the forest produce, and in any case, all pre-existing rights acquired by the people in the forests should be strictly protected. Fernow concludes with the strongly-expressed advice that a law should be passed reserving the relics of the forests of the Union, and preventing any fresh alienations. He firmly believes that such a law is most urgently required. It is, however, quite a different matter for Congress to pass any such law, though more may perhaps be expected from the separate States in the Union, and in those of New York and California some rather halting steps have been taken in the right direction.

As matters stand at present in the United States, it is pretty obvious that a time will come when landowners will look upon their private forests as a good investment, for prices of wood and other forest produce are steadily rising. Little progress has, however, yet been made in this direction, and recent attempts made by some rich men to manage their forests properly with advantage have failed.

Sir Dietrich Brandis then turns to the progress made in the study of American forest trees, and states that literature on the subject is pretty abundant, but is after all merely thrashing straw. What is wanted in America is a practical proof that in forests of the Weymouth pine, of Minnesota, or of Californian red wood, or of Douglas fir in Washington and Oregon, or in the splendid mixed broad-leaved forests of the Alleghany mountains, good forest management will prove more remunerative than wasteful pillage (*Raubbau*).

The remainder of Brandis's paper is chiefly of botanical interest, and greatly praises Sergent's magnificent work. One other passage is too interesting to be omitted. It refers to the mesquit tree, *Prosopis juliflora*, which belongs to the dry zone in the south west of the United States, and is also found in Mexico, and in the Andes as far as Chili and Argentina. In the river valleys of Arizona, where, although the air is dry, yet subsoil water is near the surface of the ground, this species forms extensive forests. On drier soils the aerial parts of the tree are reduced, but the root system is greatly extended. Sergent states that while the stem may be only a few inches high, and may only bear a few leaves, yet the tap root goes straight down to the subsoil water, and the aerial growth of the tree furnishes a clear indication of the depth at which the latter may be found.

Wherever the mesquit is a tree the subsoil water is forty to fifty feet down, where it is a small shrub it is from fifty to sixty feet down, and wherever the roots descend over sixty feet, the plant is not more than two or three feet high. In the scantily-wooded districts, where the mesquit tree grows, its roots yield most of the firewood, and are dug up, or dragged by oxen from the ground. *Prosopis spicigera* in the drier parts of India similarly furnishes fuel and cattle fodder in the Punjab, Sindh, and parts of Berar. This tree, there termed the *Jhand*, sends down its roots to a depth of fifty feet and more, to the subsoil water, and thus produces wood in a dry country, providing the peasant with fuel and wood for his plough.

W. R. FISHER.

JOHN STRONG NEWBERRY

IT is not only in the United States that the death of this veteran of scientific research will bring widespread regret. To many geologists and palæontologists in this country and on the Continent he was personally known, and those whom he honoured with his friendship will feel keenly the loss they now sustain. He was born at New Windsor, Connecticut, on December 22, 1822,

and took the degree of M.D. from the Cleveland Medical College, Ohio, in 1848. Before beginning the practice of medicine, which he intended to be his occupation in life, he spent two years in Europe. During his stay at that time in Paris he acquired a good knowledge of the French language, and had many opportunities of cultivating a love of science, which soon manifested itself as one of his distinguishing characteristics. Returning to his native country, he began practice as a medical man at Cleveland in 1851. Even at the outset of his professional work he contrived to find time also for scientific enquiry. His first published paper appeared in the same year in which he started in his medical profession. It is devoted to the geographical distribution of land and fresh-water shells.

But he soon entered upon the two branches of geological investigation in which he was to make his name familiar all over the civilized world—the study of fossil botany and of fossil fishes. As early as the year 1853 he made his first contribution to the history of Carboniferous plants, and three years later his earliest memoir on fossil fishes was published. By this time his scientific acquirements and enthusiasm were widely known. Hence when an expedition under Lieutenant Ives was organized for the exploration of the Colorado River of the West, Newberry was selected to accompany it, and to take charge of the observations to be made in natural history. His geological contribution to the famous Report at once placed him in the very front rank of American geology. His account of the geological structure of the region traversed by the expedition, and of the marvellous denudation of the cañons, will always remain as one of the landmarks of geological progress.

He had now been touched by the fascination of exploration in the far west. The drudgery of medical practice became irksome to him, so that when in the year following his return from Colorado the offer was made to him to take part in another expedition, he gladly availed himself of the opportunity. He accordingly accompanied Captain Macomb in an exploring expedition in the summer of 1859, from Santa Fé, New Mexico, to the junction of the Grand and Green Rivers of the Grand Colorado. This journey forms the subject of another masterly report by him, which, however, was not published for some sixteen years.

The shadows of the coming great Civil War were already falling on the United States, when Newberry was at work on the preparation of the record of the results of his western journeys. The storm at last burst in 1861, the same year in which his Colorado report was issued. Among the many scientific men who placed their services at the disposal of the North, Newberry took a foremost place. His medical skill and wide general scientific knowledge enabled him to be of great use to the army. He specially distinguished himself in the organization and administration of the hospital department. Among the reminiscences of his not uneventful life he had many graphic tales to tell of his experiences during that momentous epoch in the history of the United States. After the close of the war in 1865 he returned with renewed ardour to his scientific labours, and specially devoted his energies to the study of the ancient floras and fish-faunas of North America. Among his numerous memoirs on these subjects the two large monographs forming vols. xiv and xvi of the series published by the United States Geological Survey are specially worthy of notice. But they represent only a part of the enormous mass of material which he had worked over.

Prof. Newberry early in his career saw how great was the aid which geology could afford in the development of the mineral industries of his native country, and he gave himself with great energy to the practical applications of the science. He became one of the highest authorities on mining matters in the country, and he was mainly instrumental in the equipment of the great mining school of Columbia College, New York. He occupied the Chair of Geology in that establishment, and threw himself heart and soul into its duties. At last, in the midst of his work and honours, a stroke of paralysis disabled him from active duties, and he grew gradually feebler until his death. With him American science loses one of its most honoured and distinguished cultivators. His piercing eyes and well-cut features made him a marked figure in any assembly, while his courtesy and gentleness, and his unfailing helpfulness and serenity, gave him a charm which will endear his memory to a wide circle of friends.

A. G.

NOTES

ALL entomologists in the country will learn with great satisfaction that the Treasury has consented, on the recommendation of the Trustees of the British Museum, to make provision in the estimates for the coming financial year for the purchase of Mr. Pascoe's well known collection of insects. The importance of the acquisition of this collection by the nation is very great, as it contains an immense number of types, especially of the families Longicornes and Curculiones, to which Mr. Pascoe devoted so much attention for a period of more than forty years. Its dispersal or removal to a foreign country would have been an irreparable loss to British entomologists.

THE medals and funds to be given at the anniversary meeting of the Geological Society of London on February 17 next have been awarded as follows: The Wollaston Medal to Prof. N. S. Maskelyne, F.R.S.; the Murchison Medal to the Rev. O. Fisher, the Lyell Medal to Mr. F. T. Newton; and the Bigsby Medal to Prof. W. J. Sollas, F.R.S.; the balance of the proceeds of the Wollaston fund to Mr. J. G. Goodchild; that of the Murchison fund to Mr. G. J. Williams; and that of the Lyell fund to Miss C. A. Raisin and Mr. A. Leeds.

BETWEEN June 10 and 18 the University of Montpellier will celebrate the third centenary of the foundation of its Botanic Garden, on which occasion it is intended to invite a general congress of the botanists of all nations.

A MEETING of the Association for the Improvement o Geometrical Teaching was held on January 14, at University College, Gower Street, the chair being taken by the Master of St. John's College, Cambridge. The reports of the Council and treasurer having been read and adopted, Dr. Wormell was elected President for 1893, the hon. secretaries (Mr. E. M. Langley, 16, Adelaide Square, Bedford, and Mr. C. Pendelbury, 4, Glazbury Road, W. Kensington), and the other members of the Council being re-elected. Dr. Wormell having taken the chair, Mrs. Bryant gave a model lesson on geometry to a class of about twenty ladies. After an adjournment papers were read by Mr. G. Heppel on the use of history in teaching mathematics, and by Mr. F. E. Marshall on the teaching of elementary arithmetic. The attendance was larger than usual, and interesting discussions followed the lesson and the papers.

A DEPARTMENTAL committee, consisting of officers of the Charity Commission, the Education Department, and the Department of Science and Art has been appointed by Mr. Acland, Vice-President of the Committee of Council on Education, to consider the question of the organization of secondary education in England and Wales, and the relation of the Departments among themselves in connection with this subject. The Committee consists of the following members:—The Vice-President of the Council (chairman), Sir H. Longley, K.C.B., Chief Charity Commissioner, Mr. T. E. Ellis, M.P., Parliamentary Charity Commissioner, and Mr. Fearon, Secretary to the

Charity Commissioners, representing the Charity Commission, Mr Kekewich, C B, Secretary to the Committee of Council on Education, and the Rev T W Sharpe, her Majesty's Senior Chief Inspector of Schools, representing the Education Department, and Major General Donnelly, C B, Secretary of the Department of Science and Art, Captain Abney, C B, F R S, Assistant Director for Science, and Mr Armstrong, Director for Art, representing the Department of Science and Art, Mr H W Simpkinson, Examiner in the Education Department, acts as Secretary to the Committee

ON the 25th inst an influential deputation will wait upon the President of the Board of Trade to urge the adoption of the decimal system of coinage and weights and measures in Great Britain Among those who propose to form part of the deputation are the Agents General for Victoria, Queensland, and the Cape, and several prominent members of the various chambers of commerce

THE Infant University of Chicago seems to be resolved to arrange its staff of teachers on a scale commensurate with the size of the North American Continent Thus, the Department of Geology is placed in the hands of no fewer than seven distinct professors and two assistant professors, each taking some special branch of this wide science under the competent leadership of Prof T C Chamberlin Three of the professors are non-resident, but they will probably give occasional lectures, and will at least direct the studies in their own branches of research

MR JOHN D ROCKEFELLER, who had already presented the University of Chicago with 2,600,000 dollars, has now given it another million The university owns land, buildings, and other property valued at £1,400,000 sterling, and the principal is ambitious enough to hope that in course of time it may have "such an array of magnificent buildings as one sees at Oxford or Cambridge"

A BOTANICAL laboratory has been established at Eustis, Lake co, Florida, chiefly for the investigation of diseases of the orange and other species of *Citrus*, under the direction of Prof W T Swingle The anatomy, physiology, and pathology of other sub tropical economic plants will also be investigated

ON Saturday last Prof Flinders Petrie delivered his first lecture as professor of Egyptology at University College, Gower Street In the course of the lecture he said that, besides more than a thousand photographs and various impressions or "squeezes" of sculpture, a collection of original objects would be exhibited for the close examination of students Miss Edwards had formed a collection with much care—as complete and typical as possible He hoped also to place on loan his own collection, and to have a series of annual loan exhibitions drawn from the many valuable private collections in England There would thus be found a collection of deities, the most complete collection of scarabs, the only chronological collection of beads, a dated series of pottery, the largest collection of funeral cones, and also of Egyptian weights In certain lines of study their museum would not be merely supplemental, but would be in advance of any historical museums He proposed to give a series of lectures in the autumn and spring, and would prepare students who might wish to undertake practical work in Egypt, where he would spend the time before Christmas to Easter

MR ROWLAND WARD is exhibiting in his studio a valuable collection of African trophies and curiosities, most of which have been brought to England by Captain Lugard and Mr. F. C Selous Besides natural history specimens, the collection includes many weapons and products of native art.

ANOTHER severe loss has been sustained by science in Russia through the death of the well-known mineralogist, Nikolai Ivanovitch Koksharoff He died at St Petersburg on January 2 He was born on December 2, 1818, in West Siberia, in a village near which at that time was the fort of Ust Kamenogorsk, and he made his studies in the Mining Institute at St Petersburg In 1841, when he was a mining engineer in the Urals, he accompanied Murchison on his journey to Russia and to the Urals, and the intercourse with the great geologist led him to adopt a scientific career He spent the next three years studying in Western Europe, and on his return he devoted himself entirely to minerology, and especially to goniometric measurements of minerals, in which he was so much aided by his wife that his numerous writings on this subject are as much her work as his He lectured in his early years on geology and physical geography, but later on devoted himself almost entirely to the description of Russian minerals, of which he discovered and described many new ones His chief works are embodied in eleven large quarto volumes of "Beitrage zur Mineralogie Russlands," illustrated with numerous plates. The twelfth volume was in type when he died In 1866 he was made a member of the St Petersburg Academy of Sciences, and many scientific bodies of Western Europe elected him corresponding or honorary member

DURING the past week the weather has been of a very unsettled character, at first an anticyclone lay over the greater part of these islands, while areas of low pressure were situated over the North Sea and to the west of Norway With these conditions the weather became warmer in this country, the daily maxima varying from 40° to 46°, but over the Continent very low temperatures continued to be registered, the minima in Sweden varying from 60 to 65° below the freezing point, while exceptionally severe weather also prevailed over France and Germany On Sunday a depression was passing to the southward of these islands, and under its influence north-easterly gales were experienced in the eastern and southern parts of England, a sharp frost occurred over this country, accompanied by snow in most parts, while a thaw set in over Scotland and rapdidly spread southwards, accompanied by rain, the maximum temperatures reaching from 45° to 50 Subsequently the conditions were again becoming anti cyclonic, accompanied by a return of colder weather, but they were not at all settled, snow was falling on Tuesday in the south of England For the week ending the 14th instant the temperature was everywhere below the mean, the deficit ranging from 2° to 5° The amount of bright sunshine exceeded the average in the north and west of Scotland and in the south-west of England, elsewhere the amount recorded was very small, being only 3 per cent in the north west of England

Das Wetter of December last contains an account of a heavy thunderstorm which occurred at Paderborn on August 9, 1892, in which a number of living pond mussels were mixed with the rain. The observer who is in connection with the Berlin Metereological Office sent a detailed account of the strange occurrence, and a specimen was forwarded to the Museum at Berlin, which stated that it was the *Anodonta anatina* (L). A yellowish cloud attracted the attention of several people, both from its colour and the rapidity of its motion, when suddenly it burst, a torrential rain fell with a rattling sound, and immediately afterwards the pavement was found to be covered with hundreds of the mussels. Further details will be published in the reports of the Berlin Office, but the only possible explanation seems to be that the water of a river in the neighbourhood was drawn up by a passing tornado, and afterwards deposited its living burden at the place in question.

MR C F. MAXWELL writes to *Science* from Dublin, Texas, that on the night of November 29, about 8 o'clock, a very large meteor was seen passing westward, a little to the south of that place Just as it seemed to be passing the body exploded, producing a sound that was distinctly heard, resembling that of a rocket explosion or a pistol-shot After the explosion a body half as large as a full moon moved away to the westward, making a hissing or frying sound Mr Maxwell has seen no one who saw the meteor before the explosion The whole country was brilliantly lighted for a moment as if by a continued electric discharge, but at the time of the explosion the light was red and blue, or perhaps violet The sound of the explosion was heard by parties five miles west and seven miles east of Dublin, who could not have been less than ten miles apart on an air-line, and they report the sound together with the other phenomena to have been about the same as they were at Dublin

WHEN commanding the *Naïade* during the cyclone of November 6, 1891, Rear Admiral Cavelier de Cuverville had the opportunity of testing the efficiency of oil in calming the troubled waves of the North Atlantic The last number of the *Revue Maritime* contains an account of his experiences and conclusions When the waves threatened to become dangerous he gave orders to fill two coal sacks with tow steeped in oil, one of them to be suspended freely at the extremity of a spar spanned to the cat-head, the other near the bridge The effect was excellent No seas were shipped, and the vessel escaped without breaking a spar It appears that the oil takes effect upon the "breakers" due to horizontal translation produced by the wind, leaving the orbital motion or "swell" unaffected The former is the only element of danger in a rough sea It was found that two sacks, filled with 5 kgr of tow, holding 5 litres of colza or machine oil each, were sufficient to protect a vessel 75 m long The oil had to be renewed every six hours Too much oil has the disadvantage of spreading more slowly, and theoretically the best system of distribution would be one in which the oil would reach the surface from below in a large number of small drops

HERR J NAUE has been fortunate enough to discover at a prehistoric station near Schaffhausen a piece of limestone, on both sides of which are drawings like those which have been found in caves in France and in the cave at Thayngen It was found in the lowest part of the yellow "Kulturschicht" among bones and teeth of reindeer, horses, and other animals On one side are a horse, a foal, and a reindeer, while several horses appear on the other The style is not so fine as that of the Thayngen drawings, but, according to Herr Naue, they display a power of keen observation, and he points out that it was more difficult to work on stone than on a bone still fresh

THE remarkable address delivered by Prof Virchow on his assumption of the office of Rector of the University of Berlin has been issued by the German publisher, August Hirschwald, of that city The title is "Lernen und Forschen"

THE *Pharmaceutical Journal* of the present week prints the first of what promises to be a good series of papers, which are intended to make bacteriology intelligible and interesting to students, and to be of some practical value to pharmacists in business. The *Journal* rightly thinks that the time has come when pharmacists ought to make themselves familiar with the principles of "this newest department of experimental science."

LAST week Lord Kelvin delivered an interesting speech at a dinner given to the members of the new watch factory at Prescot He said it was something to be proud of that the article they were making was a triumph of mechanism There was nothing in the whole of scientific art, nothing in the results of mechanics applied to the useful purposes for mankind, that was a more splendid success than the science of watchmaking He had been all his life engaged more or less with scientific experiments, with measurements, and with instruments which their French friends would call instruments of precision They knew something of instruments of precision in electricity, and they were thankful if they could make a measurement which was accurate to one-tenth or one-twentieth per cent But what did watchmaking do? The commonest cheap watch—cheap but good—which would issue from the Prescot works would keep time to a minute a week Now a minute a week, if they made a little calculation, was something like one-hundredth per cent of accuracy, or just about ten times as accurate as they considered exceedingly good work in electrical measurements

AT a recent meeting of the College of Preceptors, Mr Foster Watson read a remarkably interesting paper on Richard Mulcaster, who was head-master of St Paul's School from 1596 to 1598 The paper is printed in the current number of the *Educational Times* Mulcaster's ideas were in some respects far ahead of those of his time The following, according to Mr Watson, were his "main educational contentions" —(1) Culture and learning for those who have the wit to profit by it, whether rich or poor Adequate knowledge for those who go into trade (2) Education for girls and women, as well as boys and men Higher education for girls who have good abilities (3) Training colleges for teachers (4) Physical training for all—boys and girls, teachers and pupils, and this to be continued in after life (5) Liberal education, with disinterested aims for the elementary schools (6) The best masters to take the lowest classes (7) Drawing and music to be taught in every school, not as "extras," but as essentials "You will notice," says Mr Watson, "that the last named five aims are only within the field of discussion even yet, they are not *faits accomplis* All this time they have been in Mulcaster's book, and Mulcaster's book—a few copies of it, very few—have been gathering dust"

THE Association of Officers of Colleges in New England have recommended the gradual adoption of the following changes in the curriculum of New England grammar schools —(1) The introduction of elementary natural history into the earlier years of the programme as a substantial subject, to be taught by demonstrations and practical exercises rather than from books (2) The introduction of elementary physics into the later years of the programme as a substantial subject, to be taught by the experimental or laboratory method, and to include exact weighing and measuring by the pupils themselves (3) The introduction of elementary algebra at an age not later than twelve years. (4) The introduction of elementary plane geometry at an age not later than thirteen years. (5) The offering of opportunity to study French, or German, or Latin, or any two of these languages from and after the age of ten years (6) The increase of attention in all class-room exercises in every study to the correct and facile use of the English language In order to make room in the programme for these new subjects, the association recommends that the time allotted to arithmetic, geography, and English grammar be reduced to whatever extent may be necessary The association explains that it makes these recommendations in the interest of the public school system as a whole, but that most of them are offered more particularly in the interest of those children whose education is not to be continued beyond the grammar school

MR. WALDO DENNIS gives in *Science* a minute and very interesting account of a snake which he watched for an hour in the woods one morning in July last It went straight up a tree "without crook or turn," and by and by lay still for a while,

basking in the sun Mr Dennis notes that while in this position it lifted up its head four or five inches and gaped Its mouth opened very wide; and when the mouth was closing, the nervous spasm, only half expended, again seized upon the jaws, whereupon they went wider than before, the spasm exhausting itself at last in a parting wriggle or two to the head "So natural," says Mr Dennis, "was this novel performance, that I involuntarily listened for that characteristic accompaniment, the little agonizing whine so common with the dog, and and not uncommon with us"

FEW things are more frequently said than that diseases of the nervous system, especially those of a hysterical character, have increased with the growth of civilization Dr de la Tourette has been trying to show, in the *Journal de Médecine*, that this is an error, and Dr D G. Brinton, in *Science*, expresses cordial agreement with him Travellers who give the soundest information on the subject, says Dr Brinton, report that in uncultivated nations violent and epidemic nervous seizures are very common Castren describes them among the Sibiric tribes An unexpected blow on the outside of a tent will throw its occupants into spasms. The early Jesuit missionaries paint extraordinary pictures of epidemic nervous maladies among the Iroquois and Hurons. During the Middle Ages there were scenes of this kind which are impossible to day

THE question as to whether electrification is produced by the friction of gases has been exhaustively dealt with by Mr. Wesendonck, who gives an account of his results in *Wiedemann's Annalen* The apparatus resembled that employed by Faraday with negative results, in the case of dry air Mr Wesendonck used air compressed to 100 atmospheres in Elkan steel bombs of 1000 litre capacity This was passed through a brass tube widening out into a cone into which a similar cone could be screwed from the opposite direction, so as to leave a conical path for the air issuing from the bomb. The second cone was connected to a delicate electrometer, which indicated any electrification produced by the impact of the air Ordinary air was thus found to give considerable negative charges, up to 1½ volt, if the cones were far apart, and positive charges if they were screwed up close But no electrification was produced when the air had been previously freed from dust and moisture. Oxygen behaved in the same way Carbonic acid, evaporated from the liquid state, imparted a strong positive charge to the brass, which was, however, reversed as soon as the cold led to the precipitation of water vapour Ordinary atmospheric dust was found to electrify the brass negatively, the charge being increased by previous drying It seems, therefore, that pure gases are incapable of producing electrification by friction, and that the effects observed are conditioned by the presence of minute solid or liquid particles

FISHES in badly-ventilated aquaria give various signs of oppression, such as restlessness, frequent gasping, mounting to the surface, leaping into the air, &c. Experiments have been recently made by Messrs. Duncan and Hoppe-Seyler (*Zeitschrift für Phys. Chemie*) to ascertain to what point the oxygen-content of the water may be lowered before fishes indicate uneasiness They were made with tench, trout, and crayfish in an elliptical glass vessel, with pipes for injecting and removing water and air, &c, in one case a pipe communicating with a chamber in which was a live rabbit, conveyed to the fishes air impoverished by the latter's breathing, while the behaviour of rabbits and fishes in the same air could be compared. With 4 to 3 cubic centimetres O in the litre of water, the fishes seemed well and content, and with the corresponding O tension in the air (8 to 11 volume-percentage) the rabbit was in no difficulty. With 1 7 to 0·8 cubic centimetres O in the water, the trout were evidently ill at ease, and, if it continued, they died. The tench and crayfish, however, stood still further reductions, the former finding relief at the surface Reduction of the O to zero soon produced the worst symptoms.

IT was long ago shown by Sir J. B Lawes that plants on ground that has been long without manure evaporate more water than those on good ground Further research has proved that transpiration is not proportional to leafy development, for it largely depends on the activity of the roots, as well as evaporative surface. M Dehérain has lately (*Ann Agr*) been led to investigate the influence of manure on the development of roots; and he finds that roots in unmanured ground have a much larger growth than in manured, having to spread more in search of the scanty nutriment If, then, a plant with small leafy growth, evaporates more water relatively than one with large, it is probably due to large root-growth procuring more water The observation of Volkens is cited, that desert plants have extraordinarily long roots Further, M Dehérain points out, the solar rays falling on a plant have a twofold work to do, viz assimilation and transpiration And these are complementary In strong leafy plants there is vigorous assimilation, so that transpiration is limited, while in the leaves (with little chlorophyll) of an "anæmic" plant a larger fraction of the solar energy is given to transpiration

IN the *American Geologist* an account is given of a preliminary examination of some specimens of a coaly mineral, having the general properties of a cannel, from the Kootanie and Lower Cretaceous of British Columbia. Their examination was of more than ordinary interest on account of their peculiar physical constitution and the great difficulty of ascertaining their connection with any of the materials ordinarily known to contribute to coal formation The main characteristics of the mineral are the total absence of structure, and the presence of tubular ramuli resembling fungus mycelia, as well as rounded cavities Angular fragments of material of the same nature as the larger rod-like bodies appear in the sections, and an amorphous substance either occurring in distinct flakes or acting as a cement to unite the rods Mr Penhallow's examination has made it probable that the origin of these coals must be sought in some other direction than modified vegetable structure It is suggested that they represent a form of fossil resin accumulated during a period when resin-bearing trees were very abundant, and possessed a structure favouring the rapid disintegration of organic tissue.

A YOUNG lady in America seems to have the power of awakening not only the intelligence but the affections of insects. Her experiences are recorded in *Science* by a friend of hers, who signs himself "B." In September some one gave her a beetle, which is described as a specimen of *Pelidnota punctata* Linn At first she kept it in a small box, feeding it with grass, leaves, and small pieces of fruits, such as peaches, pears, &c. Occasionally she would give it a drop of water to sip It would sometimes bite a little out of a leaf, would eat the fruits, and would take water eagerly From the first she would take the insect in her fingers several times a day and stroke or caress it, also putting it to her lips and talking to it all the while she handled it When she put it to her lips it would brush its antennæ over them with a gentle, caressing motion When she left her room she would shut it up in its box. One day, about two weeks after she received it, she was called out suddenly and neglected this precaution She was absent for some time, and when she returned the insect was not in its box nor anywhere to be seen Fearing that she might injure it, she stood still and called "Buggie, buggie," when it came crawling from its retreat towards her. "After this," says "B," "she would frequently leave it free in the room when she went out, and when she returned, if the insect was not in sight, she would

call it, and it would crawl or fly to her. As this was continued, it would more and more frequently fly to her instead of crawling, until at last it flew nearly every time it was called When it came in this way she would put it to her lips or to her nose, and the insect would appear to be pleased, moving its antennæ gently over her lips, or taking the end of her nose between them and touching it with a patting motion" Unfortunately this interesting beetle lost its liveliness in winter It was placed on a cloth above the kitchen boiler, where it revived to some extent, but in December it accidentally fell to the floor and soon afterwards died

THE annual report of the U S Commission of Patents for the year 1891 has been issued In addition to the usual statistical information there are added to this report two tables and two diagrams illustrative of the growth of patent-granting from 1790 to 1890, the first century of the existence of the American patent system The first table gives the patents granted in that period by years and by States to American citizens The second table does the same for patents granted to citizens of foreign countries. The first diagram has one line illustrating graphically the growth of patent-granting during the century, along with another line denoting the increase of population in the same period The second diagram has one line illustrating the growth per capita of patent-granting as a whole during the century, and other lines illustrating the growth per capita of patent-granting in the States by groups of States There is also a list of patentees and their improvements, by years, prior to the year 1800

THE first volume of the *Irish Naturalist*, a monthly journal of general Irish natural history, has just been published, and a very interesting volume it is The editors are Mr G H Carpenter and Mr R Lloyd Praeger, and they have secured from able contributors many good articles on subjects which cannot fail to be attractive to Irish readers The volume also records work done by some of the foremost of the Irish scientific societies

THE Bureau des Longitudes has issued, through Messrs Gauthier-Villars et Fils, its "Annuaire" for the year 1893. It contains, as usual, a great mass of scientific information, clearly arranged Among its "notices" is an interesting paper upon the observatory of Mont Blanc, by M J Janssen

THE Belgian Royal Academy of Science, Letters, and Art has also issued its "Annuaire" Among the contents is a rather elaborate memoir of Jean Servais Stas, accompanied by an excellent portrait

MESSRS. CHARLES GRIFFIN AND CO have published a ninth edition of "A Pocket Book of Electrical Rules and Tables for the Use of Electricians and Engineers," by John Munro and Andrew Jamieson. The authors state that the work has been carefully revised and enriched with fresh matter, including several important communications by leading authorities on electro-technics.

MESSRS. GEORGE BELL AND SONS have issued the first portion of a supplement to the third edition of "English Botany, or Coloured Figures of British Plants." This part has been prepared by Mr N. E. Brown The rest will be done by Mr. Arthur Bennett.

IN our review of "Modern Mechanism" last week (p. 242) a typical American express locomotive with 20 × 24 cylinders was said to be less powerful than an 18 × 26 cylinder British engine. This should, of course, be reversed, the American engine being the more powerful

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus* ♀) from India, presented by Mr F Skinner, eleven Tuatera Lizards (*Sphenodon punctatus*) from Stephen's Island, Cook's Straits, New Zealand, presented by Captain E A Findlay, a Puff Adder (*Vipera arietans*) from East Africa, presented by the Directors of the British East African Company, a Vulpine Phalanger (*Phalangista vulpina*), from Australia; a a Stanleyan Chevrotain (*Tragulus stanleyanus* ♂) from Java, deposited, a Sanderling (*Calidris arenaria*), European, two Brown Capuchins (*Cebus fatuellus*), an Azara's Fox (*Canis azaræ*), a Ring-tailed Coati (*Nasua rufa*), seven Glossy Ibises (*Plegadis falcinellus*), a Brown Milvago (*Milvago chimango*), four Barn Owls (*Strix flammea*), a Ypecaha Rail (*Aramides ypecaha*), a Chilian Pintail (*Dafila spinicauda*), a Geoffroy's Terrapin (*Platemys geoffroyana*) from South America, purchased, a Hog Deer (*Cervus porcinus*), born in the Gardens

OUR ASTRONOMICAL COLUMN

COMET HOLMES —The following telegram was received from Dr Copeland on Tuesday evening —"Comet Holmes reported suddenly brighter Stellar" (nucleus) We therefore continue the ephemeris (Schulhof, for Paris, midnight)

Date		R A app. h m s.	Decl app ° ′
Jan	19 ..	1 25 53 2	+33 39
	20	27 13 7	39
	21	28 35 1	39
	22	29 57 2	39
	23	31 20 1	40
	24	32 43 7	40
	25	34 8 0	41
	26	1 35 33 0	+33 42

The comet is now almost midway between β Andromedæ and α Trianguli

BURNHAM'S DOUBLE-STAR OBSERVATIONS —Mr. Burnham's splendid series of double star measures, made chiefly with the 3 foot refractor at the Lick Observatory during the first six months of 1892, are published in *Ast. Nach.* No 3141 He states that the superiority of the great telescope for this work has been fully demonstrated In the present list there are micrometric measures of eight new double stars, and additional measures of 170 old ones χ Pegasi has completed more than one revolution since its discovery in 1880, the period being about eleven and a half years, which "is probably shorter than that of any other known pair in the heavens"

Mr Burnham's connection with the Lick Observatory having permanently ended in June last, the present list of measures concludes his work on double stars It is to be hoped that the field of work which he has so brilliantly occupied will not be neglected in the future.

EPHEMERIS OF COMET BROOKS —The following is a continuation of Kreutz's ephemeris for Berlin, midnight —

Date	R A. (app.) h m s.	Decl. (app) ° ′	Log r	Log Δ.

THE ECLIPSE OF APRIL 16, 1893 —In a communication to the Astronomical Society of France, M. de la Baume Pluvinel indicates some of the points to which attention should be directed in the eclipse of the sun in April In the first place, he does not think any of the precious moments of totality need be devoted to the study of prominences, as these can now be completely studied at any time. The investigation of the corona is all-important, and attempts should be made to obtain photographs showing its general aspect with various exposures, as well as photographs of its spectrum The different parts of

the corona are of such varying brightness that it will be impossible to obtain all the details with a single exposure For the spectroscopic work it is also recommended that isochromatic plates be employed, with special reference to the distribution of the material which gives the green line 1474 Kirchoff Mr. Lockyer proposes to use an objective prism, so as to obtain monochromatic images of the corona, that is, rings corresponding to each elementary radiation of the coronal light This method will not only give the spectrum of the corona, but the distribution of each spectrum line over the whole of it The problem of the "reversing layer" is also wanting definite solution, and it is pointed out that instantaneous photographs may settle the question once for all M Pluvinel also points out the importance of noting the presence or absence of the hydrocarbon bands suspected by Tacchini in 1883, as this observation may throw further light on the analogy between the corona and the tails of comets

Photometric observations should also be secured, and the polariscope should be employed to determine the proportion of polarized light in various parts of the corona

NOVA AURIGÆ —Prof Barnard has recently made some measures of the position of Nova Aurigæ, with a view to detecting proper motion The two comparison stars selected were the stars E and F in Mr Burnham's previous list of comparison stars. The results are stated thus (*Ast Nach* No 3143) — "The measures with F come out identical with Mr. Burnham's during February, but those with E seem to show some sort of motion in distance and possibly in angle From the position of the comparison star this can hardly be due to parallax It is possible, though, if the discrepancy is a real displacement, that it is due to orbital motion, the orbit being so situated as to show no motion with reference to F The difference is not sufficiently great, considering the distance, to prove anything" Prof Barnard further remarks that although the Nova presented no nebulosity at its first appearance, it has always appeared as an undoubted planetary nebula since he observed it on August 19 Estimates of magnitude in the present condition of the Nova will depend greatly upon the telescope and magnifying power employed Since August the nucleus has become fainter, while the light as a whole has remained essentially constant

"ASTRONOMICAL JOURNAL" PRIZES — "A gentleman earnestly interested in the development and progress of astronomy in his native land has authorized the editor of the *Astronomical Journal* to offer two prizes, for resident citizens of the United States" (*Ast Jour* No 284). The prizes will either take the form of money or of gold medals, one being of the value of two hundred dollars and the other of four hundred dollars In the first instance the prizes will be awarded for observations tending to advance our knowledge of cometary orbits, one being for the best series of measurements of the positions of comets during the year ending March 31, 1894, and the other for the best discussion of the path of a periodic comet, with due regard to its perturbations With regard to the first, astronomers who hope to gain the prize must frequently be at work until sunrise, as special value will be attached to observations made at inconvenient hours.

GEOGRAPHICAL NOTES.

THE name Ibea, contracted from the initials of the Imperial British East African Company to designate their territory on the east coast of Africa, has acquired a certain amount of currency, and although open to philological criticism is practically convenient On the same principle the great Dutch possessions in the East Indies have been termed Noi (*Nederlandsch Ost Indie*), and Mr. Ravenstein has suggested a similar abbreviation for the German East African territory (*Deutsch Ost Afrika*), only he would combine the initials with a Swahili affix or suffix signifying "land," and make it either Udoa, or Doani The cumbrousness of using many words to specify a well-defined region seems to justify a somewhat bolder coinage of new names in geography than has hitherto been customary

THE *Mouvement Geographique* publishes a sketch map of the Stanley Falls district of the Congo, compiled from the compass-bearings of M. Page, one of the members of the disastrous Hodister expedition. Besides Stanley, Lieutenant Gleerup and Dr Oscar Lenz are the only other authorities on this stretch of the river Special information is given regarding the three groups of rapids which occur between Stanley Falls station and Kibonge. The cataract of Mandombe above Stanley Falls is composed of a succession of falls from six to ten feet high and numerous rapids, but local canoe-men are able to take boats through in four or five hours Three hours of free navigation leads to the rapids of Mamanga, where the river is barred from bank to bank by a ridge of rock about twelve feet high, and followed by rapids and other smaller falls necessitating a portage Three and a half hours of free navigation lead to Basundu, the last cataract, which canoes are able to pass in about three hours after being lightened

THE Antarctic whaling fleet, the dispatch of which was noticed in vol xlvi p 477, has been reported from the Falkland Islands The *Balaena*, which has the most complete scientific equipment, arrived at Port Stanley at the end of November, the *Active* on December 8, the *Diana* on December 11 The fourth vessel, the *Polar Star*, was spoken off the Plate on November 16 The telegram from Monte Video reports all well, and a preliminary notice of the scientific observations will probably follow by mail

IN a communication to the Paris Geographical Society, M Venukoff calls attention to the fact that although the extensive Government drainage works have almost obliterated the Pinsk marshes from the valley of the Pripet, the most recent non Russian atlases continue to represent these marshes as they were thirty years ago Now their site is largely forest and meadowland

TRAVELS IN BORNEO

MR CHARLES HOSE'S paper on "A Journey up the Baram River to Mount Dulit and the Highlands of Borneo," read to the Royal Geographical Society on Monday evening, was a pleasant variety in the succession of African papers which has formed the staple of the Society's programme for the session

The Baram River runs on the whole northward through eastern Sarawak, reaching the sea in 4° 37′ 15″ N and 115° 59′ 30″ E Its mouth is complicated by a series of sandbanks shifting with the change of the monsoons The river is in parts very deep, and is navigated by a fleet of Government steamers The bordering land is low and swampy or covered with jungle until Claudetown, about sixty miles from the mouth, is reached There the ground rises, and a prosperous trading town has been established by Chinese merchants At Long Mari, about fifty miles further up, there are great rapids which can only be passed with difficulty, and gorges of considerable depth occur at intervals further up the stream The journey to Mount Dulit was made up the Linjar, a large tributary of the Baram The people on the banks of this river have a peculiar custom of keeping dead bodies in their houses encased in ornamental coffins for three months before burial, and Mr. Hose gave some highly interesting particulars regarding their burial customs, their complicated subdivisions of the world of the dead, and their habit of interchanging messages with departed friends At the head of canoe navigation the Sibop tribe hunt various species of monkeys with the blowpipe, the valuable commodity being the intestinal calculi known as Bezoar stones, which are greatly in demand by Chinese apothecaries.

The ascent of Mount Dulit was commenced on September 21, when a hut was built at the height of 2000 feet, and a path cut through the thorny scrub to 4000 feet, near which another hut was built Several days were spent here collecting natural history specimens, many of which were species new to science, amongst the smaller quadrupeds *Hemigale hosei*, and amongst birds *Calyptomena hosei* and *Mesobucca eximius* may be mentioned. A cave some distance higher was found with wild tobacco growing at its mouth and several remarkable ferns, one with fronds 14 feet long; but except for bats and a solitary snake, the cave was untenanted. The fauna of Mount Dulit closely resembled that of Kina Balu, showing the widespread distribution in the highlands of Borneo of Himalayan forms The flat moss-clad summit of Mount Dulit was found to be, by aneroid, 5090 feet, and there was a magnificent view of distant ranges, the position of a number of peaks in which was fixed Some natives reported having heard a tiger roaring in the neighbourhood, but Mr Hose found the sound to proceed from a gigantic toad, measuring 14½ inches round the body. At the close of the paper Dr Bowdler Sharpe F R.S., pointed out the great importance of Mr Hose's results in their bearing on geographical distribution

BACILLI IN BUTTER.

THE fact that milk affords a particularly suitable medium for the growth and multiplication of most micro organisms, has rightly led to its being regarded as a dangerous vehicle for the propagation of disease On the Continent the practice of boiling all milk before use, and so destroying any pathogenic microbes which may be present, is almost universal, and recently a number of special pieces of apparatus have been devised for household use, ensuring the efficient so called "pasteurization" of milk In England, however, we but rarely boil our milk in spite of outbreaks of diphtheria and typhoid fever having been not infrequently traced to a particular milk supply In a paper by Cnopf on the bacterial contents of milk it is stated, that on one occasion out of every thirteen samples of milk supplied to Paris one was found to contain tubercle bacilli, whilst it is well known that the germs of typhoid, cholera, diphtheria, anthrax, &c, thrive readily in this medium But although milk has been made the subject of much careful experimental investigation, comparatively little is known of the microbial condition of butter Heim has shown that cholera bacilli purposely rubbed into butter could be demonstrated after thirty-two days, whilst typhoid bacilli similarly introduced were found after three weeks, and tubercle bacilli after the lapse of a month, although Gasperini discovered the latter in butter even after 120 days Quite recently Lafar has published a paper, "Bacteriologische Studien uber Butter" in the *Archiv fur Hygiene*, in which he has recorded his investigations on the micro-organisms found in Munich butter These experiments are instructive as exhibiting the fitness of butter to support a large number of bacteria, and thus furnish an interesting supplement to what is already known concerning the longevity of pathogenic microbes in this medium The samples examined were prepared from fresh cream and were investigated as soon as possible after the butter was made It was found that the number of microbes differed according as the portion for experiment was taken from the outside or from the interior of the piece of butter Thus in one instance whilst one gram from the centre of the pat contained 2,465,555, on the outside in the same quantity as many as 47,250,000 micro-organisms were found Taking the average of a number of examinations, it was estimated that the interior of a lump of butter possessed from 10 to 20 millions of bacteria in a single gram Lafar is inclined to regard this as an under rather than an over statement of the number, inasmuch as there are always probably present a certain proportion of microbes which will not develop at the ordinary temperature, or on the gelatine-peptone medium usually employed He graphically puts it that, in some cases it is conceivable that the number of organisms swallowed with a moderately sized slice of bread and butter may exceed that of the whole population of Europe! Lafar found that butter kept in a refrigerator, with a temperature of between 0° to + 1° C at first (after five days) showed a marked reduction in the number of bacteria, but that no further diminution took place, although the sample was kept for a month at this temperature Samples kept at from 12° to 15° C. exhibited a marked increase in the number of micro-organisms, a rise from 6 to 35 millions being observed in the course of nine days, whilst when placed in the incubator (35° C) after four days the bacteria had fallen from 25 to 10 millions, and after thirty-four days only 5 per cent of the original number present were discoverable Experiments were also made to ascertain what was the bacterial effect of adding salt to butter kept in a refrigerator It was found that although the numbers were thereby considerably reduced, that yet, even when as much as 10 per cent. of salt was added, the complete destruction of the bacteria was not accomplished. On examining, however, gelatine-plates prepared from these samples, it was ascertained that the organisms present consisted almost entirely of a pure cultivation of one particular microbe, which was apparently entirely unaffected by the addition of salt, and had grown and multiplied to the exclusion of nearly all the other bacteria originally present. When samples similarly salted were placed in the incubator (35° C) the result was rather different, for whilst there was more apparent connection between the proportion of salt added and the diminution in the number of bacteria, more varieties of micro-organisms were found on the gelatine plates. But in this case, also, the germicidal effect produced was not proportional to the increase in the amount of salt. Samples of artificial butter were also examined, and were invariably found to be much poorer in bacteria than ordinary butter Thus, whilst the smallest number found in one gram was 747,059, in real butter considerably over two million microbes was the minimum Two varieties of bacilli have been isolated and described, which were found very constantly present in butter throughout these investigations They are beautifully illustrated and shown in coloured plates as individual organisms and colonies at the end of the paper Lafar purposes continuing his investigations, and it is to be hoped that the examination of butter for pathogenic micro organisms, about which so little is known, will form an important feature in any further researches he may undertake

GRACE C FRANKLAND

THE OCCURRENCE OF NATIVE ZIRCONIA (BADDELEYITE)

THE discovery of native zirconia was first made public in my letter to NATURE (vol xlvi p 620) in October last, at the same time I gave characters sufficient for the recognition of the new mineral, and suggested the name *Baddeleyite*, in honour of Mr Joseph Baddeley who had brought the specimen with other dense minerals from Rakwana in Ceylon As there was only a single fragment of what at first sight seemed a hopelessly imperfect crystal, the determination of all the important characters without appreciable injury of the specimen was a task of an attractive kind the technical details of the investigation (including quantitative chemical analyses) and the line of argument by which definite results were evolved from the observations, were communicated to the Mineralogical Society at the meeting held on October 25 (NATURE, vol. xlvii p. 70), and crystals of hydrous zirconium oxychloride prepared by identical methods from Baddeleyite and artificial zirconia, respectively, were exhibited for comparison Having regard to the unexpected result of the chemical examination and the difference of the characters of Baddeleyite from those of artificially prepared crystals of zirconia, every care had been taken to get results as accurate as the material itself would admit of

Of course it was hoped that the occurrence of native zirconia, once established, would soon be noticed elsewhere, and in fact, I hear this morning (January 3) from Dr Hussak of the Geological Survey of Brazil, that flawless crystals of zirconia are actually met with in the south of São Paulo as an accessory constituent of an augitic rock described under the name of Jacupirangite by my friend Mr O A Derby

The Brazilian mineral had three or four years ago been regarded by Dr Hussak (who had then only a small amount of material for examination) as probably orthite (silicate of cerium, iron, &c), a mineral with which it agrees in its more obvious external characters, and it was mentioned later under that name in Mr Derby's description of the Jacupirangite, but more recently Dr Hussak, on isolating a score of flawless crystals from the decomposed rock, recognized the distinctness of the mineral from orthite, determined the geometrical and physical characters of the crystals, and decided from a chemical examination that the material was a tantalo-niobate of probably some member of the yttrium cerium group these results were published in the *Neues Jahrbuch fur Mineralogie*, 1892, Band II p 142, immediately after my announcement of the occurrence of native zirconia in Ceylon had been sent for publication, but they had been forwarded from Brazil as early as the month of June Dr Hussak now informs me that the Brazilian mineral, which had been sent to Sweden for a complete quantitative examination, has been determined by Prof Blomstrand to be almost pure zirconia

As regards crystalline form, the parametral elements obtained by myself for Baddeleyite, and announced at the meeting of October 25, agree in a very satisfactory way with those determined by Dr Hussak for the Brazilian mineral, while as regards optical characters, the two descriptions are practically identical The only important deviation of external character is in the specific gravity, that of Baddeleyite is 6 025, that of selected crystals of the Brazilian mineral is 5 006

Now it seems almost impossible that the specific gravity of crystals of a simple oxide presenting otherwise identical characters can vary to this extent, and the explanation of all the difficulty will probably be found to be that Dr Hussak's specimens really belong to two distinct minerals, that while the crystalline form and optical characters were determined from the one (zirconia), the specific gravity and the chemical composition

were originally determined from the other (yttrium tantalate) In fact, it was stated in my former communication that the Baddeleyite of Ceylon is itself associated with such a chemical compound, and I may add that this associated mineral was there designated without the mention of a species-name because it had been found to have a specific gravity (4 9) far below the inferior limit (5 5) hitherto observed in the case of undoubted Yttrotantalite: it was intended to determine later whether or not the lowness of the specific gravity was accompanied by a difference in the proportion of the chemical constituents, further, the similarity of aspect of the zirconia and yttrium tantalate of Ceylon is such that a confusion of the two would be easy. In this way the discrepancy of the chemical results and the complete accuracy of the observations of Dr Hussak, whose reputation stands so high in the annals of mineralogical science, would be found consistent with each other

There remains the inconvenience that two names have been suggested for the same mineral, but according to the rules of nomenclature formulated by Dana (rule 13*d*) the name of *Baddeleyite* has the prior claim I may add that the name *Brazilite* was in use eight years ago, commercially at least, for the specification of an oil bearing rock found in the neighbourhood of Bahia L FLETCHER

GAS POWER FOR ELECTRIC LIGHTING

AT the ordinary meeting of the Institution of Civil Engineers on Tuesday, January 10, an interesting paper on "Gas-Power for Electric Lighting" was read by Mr J Emerson Dowson The author stated that in Great Britain alone gas-engines had been sold for electric lighting, exceeding in the aggregate 7000 horse-power, and that in Germany engines were used for about 1100 arc and 90,000 glow-lamps It was, however, only within the last few years that gas-engines of large size had been before the world in a practical form The varying load factor in central stations was a serious trouble, and the author hoped to show that much of the present loss, due to fuel, water, and wages, would be avoided if gas power were used instead of steam-power

Special reference was made to the central-station at Dessau, belonging to the German Continental Gas Company That station was opened in 1886 with two 60 horse-power, one 30 horse-power, and one 8 horse power (effective) engines, worked with town-gas, and all the dynamos were driven by belting and counter-shafts In 1891 considerable alterations were made One 60 horse-power engine, with its belting and counter-shaft, was retained, and one of 120 horse-power introduced, coupled direct to its dynamo The speed of the engine and coupled dynamo was 145 revolutions per minute, and the consumption of town-gas was equal to 39 cubic feet per kilowatt Formerly, without accumulators, it was thought necessary to adjust the size of the engines to the supply, so that they should always be worked to their full extent It had, however, been found that a limited supply could more advantageously be furnished entirely from accumulators In spite of the loss of about 21 per cent in the accumulators, large engines worked more profitably in parallel than smaller ones supplying direct without accumulators Since February, 1889, the Municipality of Schwabing, a suburb of Munich, had used an Otto engine worked with Dowson gas for 10 arc- and 300 glow lamps. The load was variable, but with an average output of 22 5 kilowatts per hour the fuel-consumption was 3 3 lbs per kilowatt The town of Morecambe was lighted by nine arc-lamps and glow-lamps, equal to 1600 of eight candle-power each, the dynamos being driven by Stockport gas-engines worked with Dowson gas. With an output of only 1155 kilowatts per week the consumption of fuel was 2 58 lbs, and the cost of the gas, including wages and fuel, was ½d. per kilowatt delivered. At the château of Mr. Say, at Longpont, in the South of France, there were 650 glow-lamps and one arc-lamp, supplied by a dynamo driven by a Crossley engine worked with Dowson gas The consumption of fuel was 1·2 lb per indicated horse power, and 2·7 lbs. per kilowatt per hour

It was believed that the late Sir William Siemens first drew attention to the fact, that when illuminating-gas was burnt in a gas-engine to drive a dynamo, much more light was produced electrically than could be produced by burning the same quantity of gas in burners in the usual way. Latterly the consumption of gas per horse power in gas-engines had been reduced, and the ratio was at the present time about 20 to 1 in favour of converting the gas into an arc-light, by means of a gas-engine The author had collected data from various sources, as to the consumption of ordinary town-gas by engines supplying electric light with and without accumulators The average of all the returns, with engines under varying loads and without accumulators, was about 47 cubic feet per kilowatt-hour; when accumulators were used, the consumption of gas was less, because the engines then worked under a full load With 47 cubic feet per kilowatt, and 55 watts per 16 candle-power, one light of that power required only 2 6 cubic feet per hour, whereas a standard Argand burner required 5 cubic feet per hour. In this comparison, it was assumed that the glow lamps and gas-burners were in good order, but under ordinary working conditions they did not maintain so high a duty

The question of load-factor was a serious one with any type of engine, but with gas-engines the loss was much less than with steam-engines When a gas-engine was stopped, its consumption of fuel stopped also, and there was no furnace to maintain, nor was there any water to boil at starting. At the same time, it was desirable that the gas-engine should be worked as much as possible under a full load, and in this respect the experience at Dessau was generally confirmed A central-station was worked under trying conditions, and in the London district there was only a full output of current during from three to five hours in every twenty-four, moreover, about 60 per cent of the total output was required during that short period In practice, this meant that in a station where the current was supplied without accumulators, the engines were run at a reduced speed during a portion of the time, and at other times some of them were stopped altogether, but all had to be ready to work in the evening, and occasionally in the day time, when there was fog Generally, it might be assumed that the average consumption was more than 6 pounds per kilowatt where accumulators were used, and about 9 to 12 pounds where they were not used In any case, with the best possible arrangement of steam-power, there must be a large amount of fuel consumed which did no useful work, for, even if some of the fires were drawn, they had to be re-lighted, and the large quantity of water which had cooled during the time of standing must be re-heated.

The author believed that the solution of the difficulty was to be found in the use of gas-plant instead of steam-plant With a large gas-engine, one brake horse-power per hour could be obtained with a consumption of about 1 lb of anthracite, or 1¼ lb of coke, whereas the consumption of coal with the steam engines used for central-stations, must be taken at about 2½ lbs per brake horse-power, when working under a full load A saving of not less than 50 per cent could therefore be effected in stations where the engines were fully loaded; and where there were great fluctuations in the output, the loss of fuel with boilers not used, or only partly used, could be almost entirely avoided For a maximum of 400 kilowatts, there would be three gas-generators, each capable of supplying one-third of the maximum required The production of gas could be raised or lowered in several ways, and the working of each generator could be stopped immediately by shutting off its steam supply Supposing, therefore, that all three generators were working at their maximum rate, and a gradual reduction was required, this could easily be effected, and when the production of one or two generators could be dispensed with their operation was at once stopped The third generator could then be kept at work, and its production adjusted to suit the minimum consumption required A gas-generator had a small grate-area compared with that of a boiler, and much less cooling-surface. it contained no water, and required no chimney-draught. A generator of the size referred to lost only 6 to 8 lbs. per hour whilst standing If an average of only 40 per cent. of the maximum power were required for twenty-one hours, it was equivalent to letting two of the generators stand for that period, and at 8 lbs each per hour that meant a total loss of only 3 cwts., compared with the much greater waste when steam-power was used. As the use of large engines, driven with generator gas, was of recent date, the author proceeded to describe the gas-plant used, and gave the results of engines working regularly with Dowson gas, under the usual conditions obtaining in factories. He also gave the results of brake-tests made with several engines of large size, and reproduced indicator diagrams taken from engines of different makers. Although admirable results had undoubtedly been obtained from engines

working with the Otto cycle, he was of opinion, that, with engines of large size, the results would be still better if the cycle were altered, especially when generator-gas was used His reasons for this were fully stated in the paper

The following was a summary of the points urged by the author.—

1.—When town-gas was used for driving the engines of an electrical station, the consumption was about 50 per cent less than the volume of gas required to give the same amount of light by ordinary burners

2.—When town-gas was used, neither boiler nor firemen were required, and there were no ashes to remove; less space was needed, no accumulators were required, except such as might be necessary to equalize the load of the engines and to provide for a small amount of storage. The engines could be worked in the most crowded districts, close to where the lights were required, and where boilers were not allowed

3.—When generator gas was used, the consumption of fuel under a full load would be at least 50 per cent less than with steam-power, and the loss due to steam boilers not being fully worked could be almost entirely avoided.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—We regret to hear that Professor Cayley has been suffering from serious illness, and that he is in consequence unable to give this term his advertised course of lectures in Pure Mathematics.

L Cobbett, M A, M B, of Trinity College, has been appointed Demonstrator of Pathology in the place of Dr E Lloyd Jones, who has resigned the office

Mr F Darwin, Deputy Professor of Botany, announces a special course of lectures in the Chemical Physiology of Plants, to be given by Mr Acton, of St. John's College, on Tuesdays in the present Lent Term

Mr J. Y Buchanan, F.R S, announces a second course of lectures in Geography, to be given in the Easter Term

Mr. A. E. Shipley has been appointed an additional member of the Special Board for Biology and Geology

SCIENTIFIC SERIALS.

Journal of the Royal Agricultural Society of England, 3rd series, vol iii pt 4.—Cottage sanitation (illustrated), by H McLean Wilson, a paper prepared under the supervision of Dr Spottiswoode Cameron and T Pridgin Teale, F R S It contains a discussion of the principal sanitary defects, which are most likely to be found in the houses of agricultural labourers, with valuable suggestions and remedies. The object aimed at is "to put the whole country, and every house in the country, into such a condition that if the epidemic (cholera) should break out it would have no chance of spreading"—Field experiments on the fixation of free nitrogen, by James Mason, gives an account of the enriching of some plots of poor land on the Oxford clay at Eynsham by the growth of two leguminous crops in succession. The two crops chosen were beans and mixed clovers. So far as they go the results are striking. Prior to 1888 the land had never been cultivated or received any manure. Brought into tillage in that year two plots produced 10½ cwts. and 9 cwts. per acre of barley and oats respectively, straw included,—an excessively low return. In the autumn of 1888 the plots were treated with 20 cwts. of basic slag per acre, and the subsoil with the same amount Beans in the following year yielded an average of 46 bushels and 23 cwts. straw per acre. In 1890 mixed clovers gave a yield of 28 cwts. per acre as the average of the two plots, and in 1891 a crop of three tons clover-hay was obtained Potatoes were grown upon the plots last year, and gave an average yield of eight tons per acre. Excepting the basic slag, no manure of any kind had ever been applied to the plots. The experiments are being continued and extended.—Wild birds, useful and injurious (illustrated), by C. F. Archibald.—Utilization of straw as food for stock, by Joseph Darby. Showing methods of using chaffed straw as a remedy for the deficient hay crop of last summer, with records of previous experiences under similar circumstances.—Yew poisoning, by Mr. E. P. Squarey, Mr Charles Whitehead, Mr. W. Carruthers, F.R S, and Dr Munro. But few definite conclusions can be arrived at, owing to the conflicting nature of the information available It appears, however, (1) that both the male and female yews are poisonous, (2) the poisonous alkaloid (or alkaloids) exists chiefly in the leaves and in the seeds, (3) the fleshy part of the fruit is harmless, or nearly so, (4) the amount of poisonous alkaloid in the leaves varies considerably with individual trees, and perhaps with the season of the year. Dr Munro contributes a review of the chemical work done upon taxine, the only alkaloid in yew which has been investigated, very little is known with certainty about it, either as to its chemical nature or its physiological action As Dr Munro suggests, "yew leaves merit *exhaustive* chemical examination"—Besides the official reports, there are several short articles, including one upon the ferments of milk, abridged by Dr Munro from Prof. H. W Conn's pamphlet on the subject, issued last summer, also a paper upon the decline of wheat growing in England, by the editor

American Journal of Science, January.—The age of the earth, by Clarence King This paper contains an application of Lord Kelvin's reasoning from probable rates of refrigeration to the determination of the earth's age, aided by Dr Carl Barus's recent work in geological physics, especially his determination of the latent heat of fusion, specific heats melted and solid, and the volume expansion between the melted and solid state, of the rock diabase Thermal considerations have shown that with a given initial excess of temperature of the earth over surrounding space, and an assigned value for rock conductivity, it is possible to determine the curve of temperature from the earth's centre to its surface. It appears that for an initial temperature of 2000° C, the initial maximum temperature must still extend uniformly from the centre to within a few hundred miles of the surface for any admissible value of the age But since the pressures increase steadily as we proceed towards the centre, there must be a point at which their effect outweighs that of the temperature, and the material, though very hot, remains in the solid state Now on the data supplied by Barus's researches it is possible to state what temperatures are necessary to keep a certain representative species of rock in the fluid state at successive points within the earth. The amount of possible liquid layer is limited by the facts of tidal rigidity, which fix the maximum admissible temperature at 1950° and the age at 24×10^6 years Lower values are excluded by the gradient of temperature observed on proceeding downwards from the surface. This value, twenty four million years, agrees fairly well with the age assigned by Helmholtz and Kelvin to the sun. It is also concluded that the earth never was all liquid, that the original liquid layer did not exceed 53 miles, and that the spheroidal shape is due to the plasticity of the lithosphere as manifested under the action of very slowly applied forces.—Tertiary geology of Calvert Cliffs, Maryland, by Gilbert D. Harris.—"Anglesite" associated with boleite, by F A Genth.—Preliminary account of the iced bar base apparatus of the United States Coast and Geodetic Survey, by R S Woodward.—Some experiments with an artificial geyser, by J C Graham.—Observations of the Andromed meteors of November 23 and 27, 1892, by H A Newton.—Preliminary notice of a meteoric stone seen to fall at Bath, South Dakota, by A E Foote.—New Cretaceous bird allied to Hesperornis, by O C Marsh.—Skull and brain of Claosaurus, by O. C. Marsh

THE *Botanical Gazette* for October contains an interesting article by Mr H. L. Russell on the bacterial investigation of the sea and its floor The author has had the opportunity of carrying on bacteriological observations in sea water, both from the Bay of Naples and from the coast of Massachusetts. He finds micro-organisms invariably present in sea water, though not in such large numbers as in fresh water, even at a great distance from the shore, and to a depth of 3200 feet, and a larger number in the slime at the bottom than in the water itself Some marine forms are cosmopolitan, and the bacteria that are so universally present in sea-water and mud seem to be quite peculiar to this habitat.—Mr E. L. Berthoud describes the mode in which the geographical distribution of some plants has been greatly extended by the agency of the buffalo.—In the number for November Prof. Underwood gives a report of the proceedings of the International Botanical Congress lately held at Genoa.—Mr G W. Martin contributes an account of the development of the flower and embryo sac in *Solidago* and *Aster*.

Bulletin of the New York Mathematical Society, vol. ii No. 2, November 1892 —This number practically consists of one paper, and that a very interesting one, by Dr Emory McClintock, "On the Non Euclidian Geometry," a subject which has been more than once brought before our readers In vol. viii (1873) appeared Clifford's translation of Riemann's Habilitationsschrift "ueber die Hypothesen welche der Geometrie zu Grunde liegen" (1854) In 1883 this geometry was considered in Cayley's British Association address, and quite recently (February 25, 1892) in a translation of Poincaré's "Revue Generale des Sciences" "The chief lesson to be obtained from all non euclidian diversions is that the distinguishing mark of euclidian geometry is fixity of distance-measurement, by which alone it is possible to draw the same figure upon different scales That the same figure may be drawn upon different scales might well be laid down as the axiom necessary and sufficient to distinguish euclidian from non-euclidian geometry" To this is appended a footnote which says that this is "referred to as 'the axiom of similars' by Sir *Richard* (sic) Ball in the article 'Measurement' of the "Encycl Brit" A short article follows on the new logarithmic tables of J de Mendizábal Tamborrel (Paris, Hermann, 1891) In addition there are the usual "Notes," but no list of publications

No 3, December 1892 —This number contains a careful criticism of Ball's "Mathematical Recreations," with suggestions and discussions by Prof J. E Oliver of Ithaca, New York, and an account of Dr Julius Bauschinger's "Zweites Munchener Sternverzeichniss, enthaltend die mittleren Oerter von 18,200 Sternen fur das Aequinoctium, 1880," by Prof T H Safford "Notes" and "New Publications" follow

Wiedemann's Annalen der Physik und Chemie, No 12 —On the temperature coefficient of the electrical resistance of mercury and on the mercury resistances of the Imperial Institution, by D Kreichgauer and W Jaeger The coefficient was measured in the case of the copies of standard resistances already described The formula obtained for the resistance w_t at temperature t by two independent methods was

$$w_t = w_0 \ (1 + 0\ 0008751 + 0\ 000001251^2)$$

—Generation of electricity by friction of gases against metals, by K Wesendonck —On galvanic polarization at small electrodes, by F. Richarz.—Electric oscillations in wires, direct measurement of the moving wave, by Kr Birkeland The oscillations were produced in two copper wires running parallel to each other at a distance of 80cm They were 30m long, and ended in one direction in brass plates 40cm. square, facing two similar plates connected with the terminals of the spark gap of a powerful induction coil The potentials along the wire when the coil was working were determined by measuring the length of the sparks crossing between the knobs of a spark micrometer, one of them being connected with the wire by a sliding contact, the other leading through a telephone to earth Statical effects on the telephone were made inappreciable by laying a thread moistened with dilute sulphuric acid across the wires near the "collector" plates Under these circumstances the passage of sparks was immediately indicated by the telephone, and their length could be measured down to 0 0005mm —Determination of dielectric constants by means of the differential inductor, by Oscar Werner —Measurement of resistances by means of the telephone, by Max Wien —Diffusion of light by rough surfaces, by Christian Wiener Experiments made on cast gypsum show that Lambert's law of diffusion, according to which the brightness of a surface is independent of the angle from which it is seen, is not strictly correct. The brightness at the edge of a round surface is 0 6 times that given by his law. In the vicinity of reflection points the brightness is greater, and at the greatest brightness the angle of incidence is greater than the angle of reflection —A unit for measuring intensity of sensation, by the same.—On internal friction of solid bodies, especially metals, by W Voigt.—Measurement of the coefficient of diffusion of liquids, by F. Niemoeller.—Absolute compressibility of mercury, by G de Metz —Propagation of energy through the ether, by G. Helm.—On the utilization and action of the telephone in electrical null methods; reply to Hr Winkelmann, by E. Cohn —On the solution of sodium silicates, and influence of time upon their constitution, by F Kohlrausch —Behaviour of polarized light in refraction, by G. Quincke.—On a mercury arc light, by L. Arons.

SOCIETIES AND ACADEMIES

LONDON

Royal Meteorological Society, December 21 —C. Theodore Williams, President, in the chair.—The following papers were read —Moving anticyclones in the Southern Hemisphere, by Mr H. C Russell, F R S, Government Astronomer, New South Wales The author describes the results of his practical study of the daily weather charts for Australasia, and states that the leading fact brought out is that the weather south of 20° S latitude is the product of a series of rapidly moving anticyclones, which follow one another with remarkable regularity, and are the great controlling force in determining local weather These anticyclones are more numerous in summer than in winter, the average number for the year being 42 They usually take seven or eight days to travel across Australia in summer, and nine or ten days in winter, the average daily rate of translation being 400 miles The shape of the anticyclone appears to undergo some modification as it nears the east coast The winds on the north side of the anti cyclone are not so strong as those on the south side, and the intensity of the weather is in proportion to the difference in pressure between the anticyclone and the V depression, but the relation of the pressures varies frequently before the wind responds, the pressure appearing to be controlled from above by the more or less rapid descent of air which feeds the anticyclone Cyclonic storms are very unusual, and do not occur more than once in two or three months —The tracks of ocean wind systems in transit over Australasia, by Capt M W C Hepworth The author has examined the daily weather charts of Australia and New Zealand, and has prepared maps showing the daily positions of the centres of high and low pressures for a whole year He finds that the wind systems, which make their first appearance to the westward and south-westward, advance to the eastward rapidly, and frequently very rapidly, during the winter months, but during the summer months they usually move more slowly, and not unfrequently recurve Their progress is retarded by contact with the areas of high pressure which they encounter, the mean of the tracks of these anticyclones, moving also from west to east, appears to be across the southern portion of Australia and onward, crossing the islands of New Zealand during the winter months, but to the southward of Western and South Australia, across Victoria and New South Wales, and thence to the north eastward, avoiding New Zealand during the summer months —Rainfall of Nottinghamshire, 1861–90, by Mr H. Mellish The author has collected and discussed all the rainfall records made in the county during the thirty years, and finds that in the extreme west the mean rainfall is 27 inches or more, and that over the rest of the county it varies between 25 and 27 inches, except north of the Manchester, Sheffield and Lincolnshire Railway, where the rainfall is less than 25 inches, and in the north east towards Gainsborough, where it is not more than 23 inches The year of greatest rainfall was 1872, and of least rainfall 1887. October is the wettest month and February the driest —A new instrument for cloud measurements, by Dr. Nils Ekholm

Geological Society, December 21, 1892 —Prof. J. W Judd, F R S, Vice President, in the chair —The following communications were read.—On a Sauropodous Dinosaurian vertebra from the Wealden of Hastings, by R. Lydekker In addition to *Hoplosaurus armatus* and *Pelorosaurus Conybearei*, there is evidence of another large Sauropodous Dinosaur in the Wealden, now known as *Morosaurus brevis* Up to the present time it has been impossible adequately to compare *Hoplosaurus armatus* with *Morosaurus brevis*, but recently Mr Rufford has sent to the British Museum an imperfect dorsal vertebra of a large Sauropodous Dinosaur from the Wealden of Hastings, which enabled the required comparison to be made. The author describes the vertebra, contrasts it with that of *Hoplosaurus armatus*, and gives presumptive evidence that it should be referred to the so-called *Morosaurus Becklesi* (Marsh), which apparently cannot be separated from *M* (*Cetiosaurus*) *brevis*. He has not been able to compare Mr Rufford's specimen with the dorsals of the American *Morosaurus*, in order to discover whether the English Dinosaur is correctly referred to that genus. This paper led to a discussion, in which the chairman, Mr. Hulke, Prof Seeley, Mr E. T. Newton, and the author took part.—On some additional remains of Cestraciont and other fishes in the Green Gritty Marls, immediately overlying the Red Marls of the Upper Keuper in Warwickshire, by the Rev. P.

B Brodie The vertebrate remains occur in a very thin band of marly friable sandstone lying between two beds of green marl, though in some places the same bed has itself no admixture of sandy material Bones and teeth are so numerous that it might almost be called a bone-bed. It does not exceed three inches in thickness. It contains Ichthyodorulites of Cestraciont fishes, abundant palatal teeth of *Acrodus keuperinus*, ganoid fish-scales, and abundant broken bones, some of which may belong to fishes, others to labyrinthodonts, and amongst the latter a fragment of a cranial bone The Chairman congratulated the Society on the presence of one of its Fellows who had been connected with it for nearly sixty years, and had read his first paper almost half a century ago He hoped that the Society would still continue to receive communications from the same source of like interest and value Mr J W Davis, Mr H B Woodward, and Mr E T Newton also spoke —*Calamostachys Binneyana*, Schimp, by Thomas Hick Communicated by J. W Davis —Notes on some Pennsylvanian calamites, by W S Gresley. — Scandinavian Boulders at Cromer, by Herr Victor Madsen, of the Danish Geological Survey Communicated by J W Hulke, F R S During a visit to Cromer in 1891 the author devoted much attention to a search for Scandinavian boulders, and obtained three specimens, one (a violet felspar porphyry) was from the shore, and the other two were from the collection of Mr Savin The first was considered to come from south east Norway, and indeed Mr K O Bjorlykke, to whom it was submitted, refers it to the environs of Christiania The author considered that the two specimens presented to him by Mr Savin who had taken them out of Boulder Clay between Cromer and Overstrand, were from Dalecarlia , and these were submitted to Mr E Svedmark, who compared one of them (a brown felspar-hornblende porphyry) with the Gronklitt porphyry in the parish of Orsa, and declared that the other (a blackish felsite porphyry) might also be from Dalecarlia This paper was discussed by Mr C Reid, Mr J W Davis, the Rev P B Brodie, Dr Hicks, Mr Marr, and the Chairman

EDINBURGH

Royal Society, December 19, 1892 —Sir Douglas Maclagan, President, in the chair —Dr Hunter Stewart read a paper on an extension of Kjeldahl's method of organic analysis, and described an apparatus which he had devised for the estimation of the amount of organic carbon present in water —Prof Rutherford read a note by Dr W G Aitchison Robertson on the madder-staining of dentine Rabbits were fed on madder for some time and were then killed, the dentine being then found to be stained When other food was supplied for a time, the process of feeding on madder being resumed afterwards, two coloured layers were found in the dentine, with an intermediate colourless layer —Prof C G Knott read a paper on recent innovations in vector theory He entered into a critical examination of the anti quaternionic attitudes taken up by Prof Willard Gibbs, Mr Oliver Heaviside, Prof Macfarlane, and others. His chief arguments were (1) that the quaternion was as fundamental a geometric conception as either its scalar or its vector part—indeed more fundamental , (2) that in the development of his dyadic notation, Prof Gibbs, being forced to bring the quaternion in, logically condemned his own position , (3) that a really flexible vector analysis must be versorial, the equations $ij = k$, $jk = i$, $ki = j$, &c , being from the geometrical and physical point of view essentially rotational , (4) that the non-associative character of the vector-analysis, in which i^2, j^2, k^2, were *assumed* to be $+ 1$, rendered it totally unfit for higher physical research , (5) that this tinkering with the algebraic sign quite spoiled the real efficiency of the very beautiful quaternion operator ∇—Prof. Gibbs, for example, being compelled to introduce the (*supposed*) *new functions of operation* Pot, New, Lap, Max, which in quaternions are the very simplest of inverse functions of ∇, and are best expressed as such.

DUBLIN

Royal Dublin Society, December 21, 1892.—Prof A C Haddon in the chair.—Prof Sollas, F.R.S., read a paper on pitchstone and andesite from tertiary dykes in Donegal The author found that a microscopical examination of some remarkably fresh glassy rocks from Donegal revealed a close resemblance between them and rocks of the same age in Arran This helps to confirm the supposed great extension of tertiary dykes through the north-west of Ireland Prof Sollas next read a paper on the variolite and associated igneous rocks of Roundwood, co. Wicklow He described them as a complex of basic rocks, including altered ophitic dolerite, spilite (variolite du Drac), and spherulitic tachylite (variolite de la Durance) In connection with the epidotisation of the rock the author pointed to the excessive fissuring which it has undergone , and showed that the formation of epidote is attended with considerable diminution of volume, sufficient to account for the cracks The formation of serpentine and chlorite is attended with expansion, and chlorite can scarcely be formed without the simultaneous liberation of a disproportionately large percentage of quartz This explains the common association of chlorite with the quartz of quartz veins —Sir Howard Grubb, F R S , described a new system of mounting for monster reflecting telescopes —Mr. H H Dixon read a paper on the germination of seedlings in the absence of bacteria Seeds, the outer coats of which were sterilized, germinated in the absence of bacteria, and being kept absolutely free from bacteria did not, after growth had ceased, suffer the decay of death, but remained for more than twenty months apparently unchanged An apparatus for sterilising the outer coats of the seeds and sowing them without the introduction of bacteria was also described —A paper was communicated by Prof A C Haddon, and Miss A M Shackleton, describing some new species of Actiniæ from Torres Straits

BERLIN

Meteorological Society, December 6 —Dr Vettin, President, in the chair —Prof Assmann gave a detailed description of the meteorographs set up in the "Urania pillars" Each pillar contains a thermograph, a barograph, and a hygrograph, placed side by side in a metal case through which a rapid current of air is kept up The thermograph consists of a Bourdon spring, filled with alcohol, whose movements are communicated to an external recording lever The barograph is made of four boxes joined together, and delicately balanced by a weight, whose movements are similarly recorded externally The hygrograph consists of a bundle of hairs 2 m in length The above instruments have continued to work well after several months' use Their chief defect is due to the hygroscopic properties of the paper on which the three levers trace their record The large amount of material in the shape of meteorograms already collected has revealed a number of interesting facts Thus, for instance, the temperatures recorded on two closely adjacent pillars may differ by 1° or more not only on a warm summer day, but also during the night of November 26, the coldest of this year In one case the air was found to be warmed by the adjacent row of houses exposed to direct sunlight In another the radiation was observed to be greater opposite a gateway than in the street. The very considerable local differences of air temperature recorded on closely neighbouring pillars could scarcely have been *à priori* expected

Physiological Society, December 9, 1892 —Prof du Bois Reymond, President, in the chair —Prof Exner, of Vienna, gave a *résumé* of his researches on the innervation of the crico thyroid muscle in rabbits and dogs In each he had found a branch from the pharyngeal branch of the vagus distributed to this muscle, together with the superior laryngeal nerve, to which he has given the name of median laryngeal nerve The communication was illustrated by an experimental demonstration —Dr Hansemann stated that he had obtained photographs of microscopic objects which when placed in a stereoscope, presented an appearance of solidity. They were produced by taking one photograph of the object in focus for a given level, and then a second photograph at a different level. These photographs united stereoscopically gave the impression of solidity.—Prof Hilgard drew attention to the remarkable fact that the most civilized races of antiquity usually established themselves in dry districts This he attributed to the fact, borne out by numerous analyses of soils in America, that in dry regions the earth is far richer in mineral food stuffs necessary to plant life than in wet regions where these are largely washed out of the soil Hence in dry regions simple irrigation suffices to produce a luxuriant vegetable growth, while on the other hand the soil of most regions is very rapidly exhausted.

PARIS

Academy of Sciences, January 9 —M de Lacaze Duthiers in the chair —Drainage waters of cultivated lands, by M. P P Dehérain. An experimental investigation of the substances found in water drained from various cultivations showed that all the waters contained a fair proportion of nitrates Even beetroot, which not only utilizes nitrogen for the formation of its

albuminoids, but also stores nitrates in its tissues, gave 31, 39, and 95 gr of nitric acid per cubic metre of drainage water. Beetroot gives, however, the least quantity of nitrogen in the drained water in proportion to the crop. Next comes Turkey corn, and then potatoes. It appears certain that all nitrogen which enters the soil is either assimilated or else lost In the case of a bad harvest there is a loss both from the poverty of the crop and the impoverished state of the soil —On the small planets and nebulæ discovered at the Nice Observatory by MM Charlois and Javelle, and at the Mounier observing station, by M Perrotin. A list of eight minor planets discovered by the photographic method in four weeks, *i e* one-sixteenth of the time necessary to achieve the same result by eye observation —Dilatation and compressibility of water, by E H. Amagat. Tables are given showing the relative volumes of a quantity of water at pressures varying from 1 to 3000 atmospheres and temperatures ranging from 0° to 198°, and others showing the compressibility of water under the same conditions. This is seen to vary inversely as the pressure, and also inversely as the temperature up to very high pressures, when it begins to increase with the temperature —Observations of Brooks's comet (November 19, 1892), made at the Paris Observatory (west equatorial), by M O Callandreau —Observations of solar phenomena, made at the observatory of the Roman College during the third quarter of 1892, by M P Tacchini —On the reduction of elliptic integrals, by M J C Kluyver —On the thermal variation of the electric resistance of mercury, by M Ch Ed. Guillaume Pointing out the remarkable agreement of his results with those obtained by Messrs Kreichgauer and Jager, at the Physico-Technical Institute of Germany (see *Wiedemann's Annalen*, No 12) —On the measurement of power in multiphase currents, by M. Blondel —Absolute value of the magnetic elements on January 1, 1893 The elements for that date, determined at the magnetic observatory of the Parc Saint Maur, situated in long 0° 9′ 23″ E and lat 48° 48′ 34″ N, are the following —

	Absolute values on January 1, 1893	Secular variation in 1892
Declination	15° 24′·3	− 6′·4
Inclination	65 8·5	− 0·5
Horizontal force	0·19596	+ 0·00016
Vertical force	0·42297	+ 0·00019
Total force	0·46616	+ 0·00024

The values for the magnetic and meteorological observatory of Perpignan, long 0° 32′ 45″ E, lat 42° 42′ 8″ N, are

	Absolute values on January 1, 1893	Secular variation in 1892
Declination	14° 12′·9	− 5·9
Inclination	60 13·3	− 1·8
Horizontal force	0·22278	+ 0·00030
Vertical force	0·38933	+ 0·00003
Total force	0·44856	+ 0·00017

—On the purification of arsenical zinc, by M H Lescoeur. Zinc destined for toxicological operations can be obtained free from arsenic, antimony, sulphur, and phosphorus by two successive operations, viz. oxidation by means of nitre, and fusion with chloride of zinc.—Combinations of quinoleine with the halogen salts of silver, by M Raoul Varet —Symmetric dipropylurea and dipropylsulphourea, by M F. Chancel.—On a substance derived from chloral, or chloralose, and its physiological and therapeutic effects, by MM Hanriot and Ch Richet —On phagocytosis observed on the living animal, in the branchiæ of the lamellibranch molluscs, by M de Bruyne —New observations on the affinities of the different groups of gasteropods, by M. E. L. Bouvier.—On an anomaly recently presented by the secular variation of the magnetic needle, by M. Léon Descroix —Influence of motion on the development of fowls' eggs, by M. A. Marcacci.

AMSTERDAM.

Royal Academy of Sciences, December 24, 1892 —Prof. Van de Sande Bakhuyzen in the chair.—In a paper read by MM S Hoogewerff and W A. van Dorp, some isoimides of camphoric acid were described These were obtained by the action of $POCl_3$ or $CH_3.COCl$ on some substituted camphoramic acids. The following reaction takes place.—

$$C_8H_{14}\left\langle\begin{matrix}CO\,NHR\\ COOH\end{matrix}\right. + CH_3.COCl = C_8H_{14}\left\langle\begin{matrix}C=NR\\ >O\\ C=O\end{matrix}\right. + HCl + CH_3COOH$$

where R is put for CH_3, C_2H_5 or C_7H_7. The isoimides are very unstable, they easily add one molecule of water, re-generating the acids from which they derive By the action of heat they are transformed into the ordinary imides $C_8H_{14}\begin{matrix}-CO\\-CO\end{matrix}\Big\rangle NR$. —The same authors called attention to the fact that it seems to be a general reaction of the anhydrides of bibasic acids to dissolve in the aqueous solutions of ammonia and the primary amines, forming the corresponding acid amides · $R\left\langle\begin{matrix}CO\\CO\end{matrix}\right\rangle O + NH_2.R_1 = R\left\langle\begin{matrix}CO\,NHR_1\\COOH\end{matrix}\right.$ —Mr. Bakhuis Roozeboom dealt with the solubility curve for systems of two bodies The general form of such a curve in its totality, as yet not known even by the researches of Engel, has been encountered by the author and Mr Schreinemakers in studying the solubility of Fe_2Cl_6 $12H_2O$ in solutions of HCl The curve is a continuous one, combining the two solubilities of the hydrate, recently made known by the author It presents a summit when the proportion of Fe_2Cl_6 is the same as in the solid hydrate. Part of the solutions give on water-additions a deposit of the hydrate, part of them give redissolution The general form of the curve for double salts would be represented in its totality by a closed curve, surrounding the point, indicating the composition of the double salt With this form the same division of the solutions in regard to their behaviour on water-addition is possible as above —Prof Lorentz treated of Stokes's theory of the aberration of light The hypothesis of M Stokes, that the movement of the ether admits of a velocity-potential, is in contradiction with the supposition that, at the surface of the earth, the velocity of the ether is equal to that of the planet It might, however, be doubted whether, in M Stokes's explanation, the first hypothesis is really necessary In the present note it is shown that it cannot be avoided

MODERN ADVANCED ANALYSIS

Theory of Numbers By G B Mathews, M A Part I (Cambridge Deighton, Bell and Co, 1892)

THE book under review is a great contrast in many ways to the "Théorie des Nombres" of M Edouard Lucas, the first volume of which has recently appeared under the ægis of Messrs Gauthier-Villars The latter, reminding the reader much of the same author's "Récréations Mathématiques," exhales human interest from well-nigh every page The former is on severe philosophical lines, and may be greeted as the first work of the kind in the English language That this should be a fact is somewhat remarkable When the late Prof H. J S. Smith died prematurely many years ago he left his fellow-countrymen a very valuable legacy Fortunately he had been commissioned by the British Association to frame a report on the then present state of the Theory of Numbers, a subject with which he was pre-eminently familiar, and in which his own original researches had won for him a great and world-wide renown The pages of the reports for the years 1864–66 inclusive yield as a consequence a delightful account of modern research in this recondite subject It is, however, much more than a recital of victories achieved by many able men in many special fields Prof Smith's fertile genius enabled him to marshal the leading facts of the theory, and to impress upon them his own personality in a manner that was scarcely within the reach of any other man He contrived to impart a glamour to those abstract depths of the subject to which few mathematicians have sufficient faith and energy to penetrate Since that day the scientific world has been yearly expecting his collected papers There is no doubt that their appearance will greatly stimulate interest and research in Higher Arithmetic The reports of the British Association are not sufficiently accessible Doubtless the papers will soon emerge from the hands of those upon whom has devolved the responsibility of their production In the meantime we welcome Part I of the present work

The theory of numbers is the oldest of the mathematical sciences, and may be regarded as their sire Just as applied mathematics is based on pure, so pure mathematics rests on the theory of numbers Every investigator finds that sooner or later his researches become a question of pure number Continuous and discontinuous quantity are indissolubly allied The theory of series, the theory of invariants, the theory of elliptic functions throw light upon and receive light from higher arithmetic Algebra in its most general sense is everywhere pervaded by numbers. It may safely be affirmed that there is nothing more beautiful or fascinating in the wide range of mathematics than the interchange of theorem between arithmetic and algebra. A proposition in arithmetic is written out as a theorem in continuous quantity or conversely an algebraic identity is represented by a statement concerning discontinuous quantity In this country the more recent advances in this attractive method are in large measure due to the labours of Sylvester and J W. L Glaisher. In a "Constructive Theory of Partitions," published some half-dozen years ago in the *American Journal of Mathematics*, Sylvester showed some beautiful progressions from arithmetic to algebra, and was followed in the same line by Franklin, Ely, and others, whilst in the pages of the *Quarterly Journal of Mathematics* and *Messenger of Mathematics* Glaisher has applied elliptic function formulas to arithmetical theory The famous theorem which asserts that every number can be composed by four or fewer square numbers, was due to an application by H J S Smith of elliptic functions to arithmetic These interesting matters are not alluded to in this first volume

Chapter I discusses the divisibility of numbers and the elementary theory of congruencies Euler's function $\phi(n)$, which denotes the number of positive integers, unity included, which are prime to and not greater than n, is not treated as fully as might be desired Gauss's theorem

$$\phi(d) + \phi(d') + \phi(d'') + \quad = n$$

where d, d', d'', are all the divisions of n (unity and n included) is given, but not some interesting theorems connected with permutations, of which this is a particular case Sylvester has written much about the same function, which he calls the "totient" of n M Ed Lucas employs the term "indicateur" in the same sense, and believing that there is a great convenience in having a special name for the function, we regret that Mr Mathews has not taken a course which would have familiarized students with Sylvester's nomenclature, and have enabled them to feel at home with much that has been written by him and others in this part of the theory of numbers

The author states that this chapter is substantially a paraphrase of the first three sections of the "Disquisitiones Arithmeticæ," the classical work of Gauss, we are inclined to think that advantage would have been gained if the paraphrase had not been quite so close The next succeeding chapters are occupied with "Quadratic Congruencies" and the theory of "Binary Quadratic Forms"

The account given is fairly complete. There are so many proofs of Legendre's celebrated "Law of Quadratic Reciprocity" that it must have been difficult to make a selection A wise choice has, we think, been made of Gauss's third proof as modified by Dirichlet and Eisenstein, the latter's geometrical contribution to the proof taken from the twenty-seventh volume of Crelle is, in particular, of great elegance. Gauss's first proof is also given, as well as references to several others. In the difficult subject of Binary Quadratic Forms, the author keeps well in view the close analogy with the algebraic theory of forms, so many additional restrictions present themselves that a large number of definitions are requisite at the outset, and this circumstance is apt to repel a student who approaches the theory for the first time The definitions, in fact, constitute the alphabet of the science which must be mastered before progress can be expected in the appreciation of the wonderful beauties which are inherent in it In this subject, more almost than in any other, the initial drudgery must not be shirked, and it may be said in favour of the present work that clearness of definition and conciseness of statement help the learner much to get quickly over the wearisome preliminaries

We are glad to see the prominence given to the geometrical methods of Klein and Poincaré, that of the former is based on the theory of substitutions, reminding the reader much of the "Icosaeder", that of the latter s the "Method of Nets," a most ingenious geometrical application throwing light on the theory of "Reduced Forms"

The "Composition of Forms" given in Chapter VI is logically and judiciously developed, by means of the bilinear substitution, u,, to the point of showing the method of tabulating the primitive classes of regular and irregular determinants The chapter on cyclotomy is one of the best written in the book. The discussion of the section of the periods of the roots of unity has engaged the attentions of mathematicians of the first rank since the time of Gauss, so that of necessity much has been written, and while the author states that he has given but an outline of an extensive theory which has not yet been completed, it may be said that the theory as given, with the references to authorities at the end of the chapter, will be quite sufficient to conduct the student bent upon research to the frontiers of the unknown country

The determination of the number of properly primitive classes for a given determinant, applications of the theory of quadratic forms, and the distribution of primes complete the volume Mr Mathews may be congratulated on his resolve to include Sylvester's masterly contraction of Tchébicheff's limits with reference to the distribution of primes, the reader is taken from the "sieve" of Eratosthenes to the work of Legendre, Meissel, Rogel, Riemann, and to the latest researches of Sylvester and Poincaré, of which the ink is scarcely dry English mathematicians will turn with delight to the account given on page 302 of Riemann's great memoir of 1859, which contains the only satisfactory attempt to obtain an analytical formula for the number of primes not exceeding a given numerical quantity

In conclusion, though the sequence of the subject matter may be open to criticism, we regard the book as a most valuable contribution to the small library of higher mathematical treatises that, owing chiefly to the energy and enthusiasm of the rising generation of mathematicians, is being brought together How woefully deficient that library was but a few years since those engaged in research know only too well, and greatly do they rejoice as they see the yawning gaps one by one efficiently filled up Part II of the task Mr Mathews has set himself to accomplish will, we hope, soon appear, and we trust he will be as successful with it as with the present Part I

P A M

THE DARWINIAN THEORY.

Darwin and After Darwin; an Examination of the Darwinian Theory and a Discussion of Post-Darwinian Questions By George John Romanes, M A, LL D, F R S I. *The Darwinian Theory* (London: Longmans, 1892)

WE had hoped ere now to have received the second instalment of this work, and to have dealt with the two volumes in a single critical notice Unforeseen causes, one of them deeply to be regretted, have presumably prevented the appearance of the discussion of Post-Darwinian questions so early as had been anticipated. We therefore propose to give a short expository notice of the present volume, reserving such criticism as we have to offer for a future occasion, when the second volume shall have come to hand

The first section consists of an exposition of the scientific evidences of evolution as a fact independent of the Darwinian theory of the method by which this evolution has been brought about It may be regarded as an expansion of the author's little volume in the "Nature Series," on "The Scientific Evidences of Organic Evolution," published ten years ago. Mr Romanes has spared no pains in the collection and marshalling of his evidence His object is to convince, by the abundance of facts and by logical inferences based thereon, those who still hold by the tenets of Special Creation Whether those who still hold by these tenets are likely to be influenced by the facts or the inferences is a question we do not propose to discuss The author evidently supposes that they are, and has written for them a good many pages in a strain of which we give a couple of examples —"It would seem most capricious on the part of the Deity to have made the eyes of an innumerable number of fish on exactly the same ideal type, and then to have made the eye of the octopus so exactly like these other eyes, in superficial appearance, as to deceive so accomplished a naturalist as Mr Mivart, and yet to have taken scrupulous care that in no one ideal particular should the one type resemble the other" Again, "Although in nearly all the numerous species of snakes there are no vestiges of limbs, in the Python we find very tiny rudiments of hind limbs Now, is it a worthy conception of Deity that, while neglecting to maintain his unity of ideal in the case of nearly all the numerous species of snakes, he should have added a tiny rudiment in the case of the Python—and even in that case should have maintained his ideal very inefficiently, inasmuch as only two limbs, instead of four, are represented?"

The second section of the volume is devoted to the setting forth of the theory of natural selection as it was held by the master This, as was to be expected, is a well-ordered and lucid exposition. We could wish that Mr Romanes had been more careful to avoid all appearance of personifying natural selection He says, for example, "It is the business of natural selection to secure the highest available degree of adaptation for the time being." Such language is highly metaphorical, if not misleading If we can talk of business at all we may say that it is the business of various eliminating agencies, in the struggle for existence, to weed out and exclude from any share in perpetuating their race all those individuals who are too weakly to stand the stress of the struggle. The survival of the fit is an incidental result of the stern business of elimination. It is here that the naturalistic hypothesis differs most markedly from the teleological interpretation of nature In conversation a while since a friend observed to us. Since your school of thought admit that the eye of natural selection is ever on the watch for the slightest improvement in adaptation, why should they hesitate to say with us that it is the eye of Beneficence that is thus ever watchful? The misunderstanding of the naturalistic position here

shown is not surprising. It is due to the too free use of metaphorical language on the part of expounders of the Darwinian hypothesis

In the chapter entitled "Criticisms of the Theory of Natural Selection," an interesting digest is given of the work of Prof Ewart and others on the electric organ of the skate, concerning which Mr Romanes says, "I freely confess that the difficulty presented by this case appears to me of a magnitude and importance altogether unequalled by that of any other single case—or any series of cases—which have hitherto been encountered by the theory of natural selection" And he adds, "So that, if there were many other cases of the like kind to be met with in nature, I should myself at once allow that the theory of natural selection would have to be discarded," by which he means, we presume, that the theory would have to be discarded as offering a solution of such cases

The book contains many excellent illustrations, the series which show the variations due to artificial selection being a noteworthy feature They, and the volume which contains them, will prove of service to those general readers for whom, as the author tells us in his preface, this exposition of the Darwinian theory has been mainly prepared

FERNS OF SOUTH AFRICA

The Ferns of South Africa, containing Descriptions and Figures of the Ferns and Fern-allies of South Africa By Thomas R. Sim 275 pp, 159 plates (Cape Town and Johannesberg J C Juta and Co London Wm Wesley and Son, 1892)

THE present work will be a useful and acceptable addition to our stock of fern books It contains descriptions and plates of all the ferns and fern-allies known to exist in Africa south of the tropic of Capricorn, the same area which is included by Harvey and Sonder in their "Flora Capensis," three volumes of which, including the orders from Ranunculaceæ to Campanulaceæ, have been published. The author won the Jubilee gold medal given by the North of Scotland Horticultural Association, and for many years has filled the post of curator of the Botanic Gardens at King William's Town Several years ago Mr Sim published an illustrated handbook of the ferns of Kaffraria, and now he has extended his area so as to include the whole of South Temperate Africa

The fern flora of the Cape does not show the same richness and remarkable individuality which characterises its phanerogamic flora It is probable that the flowering plants of this area are not less than ten thousand, and the number of large endemic genera and of species is very considerable In ferns we get in South Africa 179 species, out of which 42 species, or something under 25 per cent., are endemic There is no genus that is peculiar to the Cape, of Mohria, which comes nearest, the Cape species, *M caffrorum* extends to Madagascar and Tropical Africa, and two new species have lately been found in the high regions north of the colony. The section Rhizoglossum of the genus Ophioglossum, which differs from the true adder's tongues by having the fertile spike separate from the barren frond, the single species, *O. bergianum*, is peculiar to the Cape. Hymenophyllum is represented by 8 species, Trichomanes by 5, Adiantum by 6, Cheilanthes by 8, Pellæa by 14, Pteris by 7, Lomaria by 5, Asplenium by 25, Nephrodium by 12, Polypodium by 12, Acrostichum by 8, and Lycopodium by 8 species Some of the species, *e g Vittaria lineata*, *Marattia* and the two tree-ferns, are tropical types, some, such as *Cystopteris fragilis* and *Lycopodium clavatum*, are common to Britain and the Cape *Todea barbara* is confined to the Cape and Australia, and abundant in both areas *Lomaria alpina* is a plant of all the three south-temperate areas *Blechnum australe* of the Cape is not, I think, really distinct specifically from *B hastatum*, and is widely spread in South Temperate America

Lomaria punctulata is remarkable for its polymorphic fructification, which is sometimes like that of a Scolopendrium *Asplenium lunulatum* is remarkable for its variability in outline and cutting

Mr Sim gives introductory chapters on the parts of ferns and their nomenclature, on their reproduction and propagation, on their cultivation and the preparation of herbarium specimens, and on the history of the discovery of the Cape species and the books and papers that have been written about them His statistic table on page 34 needs much revision in some of its items He gives the ferns of Madagascar at 144 The number now known in the island is 326 true ferns and 40 fern allies, a total of 366 There are nothing like 683 species and 458 endemic types in Africa and its islands. When I counted them up in 1868 I made the two figures 346 and 127 Since that date probably 100 species have been added Madagascar, Bourbon, and Mauritius are very rich in ferns, but Continental Africa is very poor both in number of species and in peculiar types as compared with Asia and America

The descriptions are carefully drawn up from the study of actual specimens, and by the aid of these and the plates there can be no difficulty for any one, even without any previous botanical knowledge, in making out the name of any reasonably complete specimen of any of the Cape species

Therefore, no doubt, the existence of such a book will give a great impulse to the study of ferns by ladies and others who reside in or visit the Colony

J G BAKER

OUR BOOK SHELF

Newcomb-Engelmann's Populare Astronomie, Zweite vermehrte Auflage Herausgegeben von Dr H C Vogel (Leipzig. Wilhelm Engelmann, 1892)

THE well known Popular Astronomy of Prof Newcomb was translated into German by Rudolf Engelmann, and published in 1881 with considerable additions and alterations, most of which were improvements It was very favourably received on its first appearance in German, probably because it is not only comprehensive, exact, and scientific, but has a fresh and vigorous style, in pleasing contrast to the ponderous German standard works The original translator being dead, the publishers entrusted the work of preparing a new edition to Dr H C Vogel, Director of the Astrophysical Observatory at Potsdam, a task for which he was specially fitted, because astronomical progress during the decade since the appearance of the first edition of the book has been mainly in his special

department. Dr Vogel's chief difficulty has been to keep the book within reasonable limits while bringing it up to date, but he has not been wholly successful in this. By a slight further enlargement of the book he might without difficulty have very much increased its value. A description of the diffraction spectroscope should have been given in the section on spectroscopes; Prof Hale's work in photographing prominences and faculæ should have been introduced; the chapter on Mars is very much behind the times, and some details should certainly have been given of the international scheme for photographically charting the stars.

Dr Vogel has considerably altered the arrangement of the chapter on comets and meteors, and this alteration has led to the curious result that the same woodcut appears as Figs 152 and 165. The chapter on stellar astronomy is also recast, the editor's own latest classification of star spectra being given to the exclusion of all others. The section on variable stars has also been entirely rewritten. These chapters would have been much improved by an account of recent discoveries as to the resemblances between comets, nebulæ, and stars, and of the theory that variable stars are formed of revolving swarms of meteorites. The classification of star spectra which recognises an ascending and descending temperature should have been given, and recent work and theories on temporary stars certainly deserved attention. The bibliography given in the first edition has been omitted in the second, as being too much for the general reader, and insufficient for the student of science. The excellent series of biographical notices in the appendix has been carefully extended to 1891, and completely rearranged. Dr Vogel has adopted the admirable plan of arranging these notices chronologically in order of death, instead of birth, probably on the grounds that all work is largely the result of previous discoveries, and that the later years of a man's life are usually his best and most productive. A series of excellent tables and a full index complete the volume.

The general appearance of the book has been much improved by the use of new woodcuts for the illustrations, and by the substitution of two excellent photographs of nebulæ (those of Orion and Andromeda) for the very unsatisfactory star charts of the earlier edition.

A. T.

The Hemiptera Heteroptera of the British Islands. By Edward Saunders, F.L.S. (London: L. Reeve and Co., 1892.)

IT is now nearly thirty years since Douglas and Scott first made the study of the British Hemiptera Heteroptera possible to ordinary students by the publication of a description of these insects in a volume issued by the Ray Society. The difficulties were then very great, for purely insular ideas in entomology were prevalent, and our hemipterous insects had not been sufficiently compared with continental species. Douglas and Scott did all that was possible at that time and produced a good work that has held the ground as the best published authority on the subject. Very much, however, has been done since that period, and restricted specialists in entomology, as in most other branches of natural science, have exercised unlimited time and patience in studying the classificatory problems of a single family or even of a large genus. Hence in a monograph of to-day the standard of advanced classification and descriptive facility is considerably raised from that which dominated the writings of the earlier authors. Mr. Saunders has not only aimed at this perfection, but has sought to place in the hands of the British student and collector a thoroughly trustworthy handbook by which he may understand and identify his collection, and in this we think the author has altogether succeeded. We must not look for bibliographical references or synonymical notes, the names of the describers of families, genera, and species being only indicated, while the habitats of the species are confined to such localities in the British Islands as are recorded by collectors, and this is perhaps all that can be expected in a local monograph. It is therefore in no spirit of criticism we express a regret that in all faunistic writings the complete recorded distribution of the species is not given. Thus even the purely British collector would not be the worse for learning that *Zicrona cærulea*, to be found in the suburbs of London, is not only widely distributed throughout the Palæarctic region, but is also found in Continental India and in the Malay Peninsula and Archipelago; or that *Ischnorhynchus resedæ*, to be taken even at Hampstead, is common throughout Europe and Siberia, and is also neither scarce in North nor in Central America.

We welcome Mr Saunders's book as a distinct and valuable addition to our insular entomological literature. We also notice that an illustrated edition is advertised, but on the quality of the plates we are compelled to be silent, as the publishers have only forwarded us a plain copy.

W. L. D.

Physical Education. By Frederick Treves, F.R.C.S. (London: J. and A. Churchill, 1892.)

THIS essay is reprinted from the "Treatise on Hygiene" by various authors, edited by Stevenson and Murphy, the first volume of which we recently reviewed (NATURE, vol. xlvi. p. 609). It well deserves to be issued separately, for the author has mastered his subject thoroughly, and sets forth his ideas in a plain, straightforward style which will be cordially appreciated by readers who are especially interested in athletics. Mr Treves is quite as strongly conscious of the evils which may spring from excessive or unsuitable physical exercise as of those which may result from physical exercise being neglected or underrated, so that there is a welcome tone of perfect impartiality in all he has to say about the various ways in which efforts are made to promote health by the use of the muscles. The volume may be confidently recommended to all who desire to understand the conditions under which physical exercise is most likely to be of service.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Geology of the North-west Highlands.

IN the kindly review of my work by Prof. de Lapparent, which appeared in NATURE of 5th inst., there are one or two inaccuracies which I would at once have corrected had I not shrunk from drawing attention, even for purposes of rectification, to an article which I felt to be too eulogistic. Lest, however, my silence be misinterpreted, there is one point on which I wish to say a few words. Prof. de Lapparent, when alluding to the solution of the problem of the geological structure of the North-west Highlands, makes no reference to the distinguished part taken in that subject by Prof. Lapworth. But every one who has followed the progress of geology in recent years is familiar with his work. For myself, I have had no personal share in the discovery. Like most geologists I had accepted the views of Sir Roderick Murchison, and I held to them, until, after the Geological Survey was for the first time extended to Sutherland in 1883–84, I was finally convinced that they were untenable by the brilliant mapping of my colleagues, Messrs. Peach and Horne, who, following Prof. Lapworth's lead, share with him in the glory of one of the greatest achievements of field geology in recent times. My recantation was published in NATURE of November 13, 1884, and the whole history of the investigation of the North-west Highlands up to Prof. Lapworth's latest paper

was sketched in a detailed Report communicated by me to the Geological Society on April 25, 1888 My friend Prof Lapworth has no scientific comrade who has more frankly and practically acknowledged his great geological achievements than I have done ARCH GEIKIE.

January 23, 1893

The Identity of Energy

I AM glad to see that in the introduction to his severely-difficult memoir, published in the *Philosophical Transactions* for 1892, "On the Forces, Stresses, and Fluxes of Energy in the Electromagnetic Field" (p 427), Mr Oliver Heaviside notices and criticizes some ideas of mine, published in the *Philosophical Magazine* for June 1885 and other places, concerning energy

The statements I then made, and to which I still rigidly hold, are (1) that energy has identity like matter, and not merely conservation, (2) that whenever energy is transferred from one body to another, it is also transformed from potential to kinetic, or *vice versâ*

The basis of the first assertion is the fact that energy is always passed on continuously through space, *i e* that its transfer occurs along a definite path, instead of merely appearing in one place and disappearing in another

The law of conservation would be satisfied by disappearance and equal reappearance, the law of identity requires a continuous act of transfer. The latter is true for matter, and I assert that by thinking of a number of instances, it will be perceived true for energy In all mechanical instances, as of belts and shafting, the transfer of energy is obvious, it was not so obvious in electromagnetic actions, between dynamo and motor for instance, until Prof Poynting clearly demonstrated that it was in accordance with Maxwell's principles

Mr. Heaviside objects that we are not able to assert it for gravitational energy Well, that depends on what view we take of gravitation, but I submit that until something more is certainly known about it, the safest plan is not to assert, but to assume, that in this case also what is known in every other case likewise occurs, and to trace the consequences of the hypothesis in the hope that it may lead to some conclusion verifiable or falsifiable by experiment The reason I attach importance to this doctrine of the identity or continuity of transfer of energy is because it greatly simplifies the fundamental mechanical laws, and emphasizes without risk of vagueness the denial of action at a distance

If action at a distance (no matter how minute) can ever occur, then indeed the continuous transfer of energy breaks down But observe that there is no necessity for the transfer to occur at a finite velocity in order to avoid action at a distance, *i e* action without a medium By the thrust of an incompressible pole, energy is transferred from butt to tip just as really as if the compressed and recoiling layers could be demonstrated and its velocity measured So likewise the pull of gravitation may be (and *pro tem* I believe is) transmitted by an incompressible (or nearly incompressible) ether, so that the force is felt instantaneously (or nearly instantaneously) at all distances where matter exists, but that by no means militates against a genuine act of transfer The conservation of matter makes experiments on gravitation difficult; if we could suddenly create or destroy a piece of matter there might be some remote chance of determining the rate at which its gravitative influence was felt Especially if by alternately generating and destroying it we could set up a series of waves of perhaps measurable length

And although this is as yet impossible, many known facts lead us to conclude that if gravitation has any velocity at all short of infinite, it is at least immensely greater than the speed of light. And seeing that the one phenomenon is concerned with the transverse (electric) elasticity of ether, and the other with its longitudinal elasticity, there is nothing surprising in that

By all means, however, as Mr. Heaviside urges, let gravitation be included in general etherial equations whenever possible; and it may perhaps be wise to assume some unknown finite rate of propagation and trace its consequences with the object of verifying or disproving them

So far as I understand, however, this is not unlike what Helmholtz did, by his generalization of Maxwell's electromagnetic theory; with the result that the course of experiment so far has been to justify the simple Maxwellian theory, and to make the longitudinal ether thrust velocity practically infinite.

And now for the second assertion, that whenever energy is transferred from one body to another, it is also transformed, and *vice versâ* This is to me not an opinion, but a demonstrated theorem (as has been shown in the paper referred to), but it must be understood in what sense I consistently use the word body in this connection I do not necessarily mean a visible lump of matter The molecules of a lump are to be regarded as a different "body" to the whole mass, and again, the ether everywhere embathing them is another distinct "body"

But so long as a piece of matter is merely moving through space with all the energy it may happen to contain, I do not consider that a transfer at all There is a transfer of energy in one sense, viz that of locomotion, but there is no transfer from one body to another except when work is done at their point of contact, and energy gained by one and lost by the other, being transferred across their common boundary surface In all such cases of "activity" the energy transferred is necessarily in the first instance transformed, though by means of another transfer it may very speedily be transformed back again, and so speedily sometimes is the re-transformation effected that the intermediate condition has a tendency to get overlooked In wave-motion a transfer and transformation occurs during every quarter period

Mr Heaviside seems to think that the mere convection of energy should be included as one kind of transfer, but surely that is scarcely convenient? So long as energy retains its form and adherence to one body, so long there is no true activity, no work is being done—the energy is simply stored It may be stored in a bent spring, or in a flying bullet, or in a revolving fly wheel It is impossible to have kinetic energy at all without convection, and a distinction must be drawn between the mere existence of energy and the active and useful flux or transfer of the same.

Mr Heaviside further seems to consider circuital fluxes of energy as strange and useless phenomena. But I see no reason in this at all The circulation of matter—for instance in the inner circle of the Metropolitan railway—is, I suppose, considered useful The circulation of commodities is the essence of commerce So does the circulation of energy constitute the activity of the material universe It is the act of transfer that is beneficial (or the reverse), what becomes of a conservative quantity is a minor matter It must go somewhere, and may very well, after a series of transfers, ultimately return to its starting point [Parenthetically I should like to preach here against what I hold to be the pernicious doctrine of (at least amateur) political economists, that because money locally spent is not destroyed, but remains in the community, it does not much matter how much transferring power is permitted or granted to one individual,—as if the money itself were the useful commodity, and not the power of determining its direction of transfer or non-transfer The control of every transfer should be jealously watched, for that is the greedily-desired power]

So long as circuital convection of energy goes on *without* transfer—as, for instance, in the rim of a non-working fly-wheel—so long the energy is merely *stored*, but directly a belt is fitted on with different tensions in its two halves, a portion of the energy is tangentially tapped off, and transfer and activity begin The kinetic energy of the wheel is converted into strain or stress energy of the belt, which then by simple locomotion passes it on to something else. I perceive, however, that there is a slight difficulty about this simple case of locomotive conveyance of stress energy by a really inelastic substance; but only because the details of any infinitely rapid process are difficult to follow I perceive moreover that in many cases it is not worth while to attend to the alternate compressions and motions which constitute a longitudinal pulse, and that the idea of simple locomotion may be conveniently introduced to cover the case of a stressed body moving; but the convenience is I think only attained by shutting our eyes to the essential processes which in all actual matter must be occurring

I trust that Mr Heaviside may find time to notice this letter, and attack anything he disagrees with, in order that the whole matter may become thoroughly clear. OLIVER LODGE

A Proposed Handbook of the British Marine Fauna

I AM obliged to Prof Thompson for his criticism of my scheme, although only one of the points he raises is new to me —as I think it will be to most zoologists—viz that "there are *no* nematophores on the stem" in *Antennularia* I thought *A*

ramosa had nematophores on the stem, *and I think so still* Some of his other remarks are so very obvious as to have scarcely required mention, at any rate to biological readers, a few, however, are just such debateable points as I was anxious to have opinions upon from as many naturalists as possible, and I am glad to know Prof Thompson's. I am glad to say a number of biologists have written to me, since the scheme appeared in NATURE, expressing general approval, and criticising various points of detail, and some of them kindly making offers of assistance in special groups—and without that kind of assistance from specialists I need scarcely say it would be impossible to carry out the work satisfactorily The proposal was first brought before the Biological Society of Liverpool on November 11, and it was only after some weeks of intermittent discussion with some of my friends in that Society (such as Dr Hanitsch, Mr Isaac Thompson, and Mr A. O Walker) who are specialists in certain groups of marine invertebrata, and after correspondence with Canon Norman and other biologists, that I sent the scheme to NATURE, with the view of getting further opinions Consequently some of the debateable matters alluded to by Prof Thompson (limits of British area, introduction of certain non-British forms, specific nomenclature, how to treat records of size and distribution, best terms to use for zones of depth, and, I may add, for relative abundance) have already been considerably discussed The other points raised by Prof. Thompson in connection with *Antennularia* only require a few words I said *A ramosa* was *usually* branched Prof Thompson says it "may sometimes" be unbranched The difference between these statements is slight. As to dimensions, a zoophyte which grows to 12, or occasionally to 24, inches in height, will, of course, be also frequently found of smaller sizes, and it might be the best plan to give the extreme range, say, 1 to 24 inches What I gave was the fair average size of most of the specimens dredged or seen in collections, which I still consider to be 6 to 9 inches.

The rest of Prof. Thompson's contention is practically that there are great difficulties in the way of drawing up such a book of the known British marine invertebrate animals, and that if it is ever done it will be more or less incomplete, because Canon Norman and others (I hope including both Prof Thompson and myself) will continue to find new British animals That is perfectly true—in fact obvious—but the same objection applies more or less to every work on systematic zoology that has ever been published, and I do not consider that because our British Pycnogonids, and some other small groups, are still very imperfectly known, that is any sufficient reason for delaying indefinitely an attempt to deal with the rest of the invertebrata. On the contrary my opinion is rather that an approximation is better than nothing, and that every group, or every family, reduced to "Handbook" form with specific diagnoses and figures must be a distinct gain I hope Prof Thompson will not think that I am trying to dispute all his criticisms, or that I am ungrateful for the trouble he has taken I have no doubt that he could correct me in many details, and give me great assistance in records, &c, of zoophytes, pycnogonids, and other groups, and I hope he will do so W A HERDMAN

University College, Liverpool, January 20.

PROF D'ARCY THOMPSON'S letter raises a question which is, I think, well worthy of Prof Herdman's consideration That a handbook of our marine fauna is needed cannot for a moment be doubted, and the only matter that calls for discussion is one of scope and method, of ways and means Prior to the appearance of Prof Herdman's circular and article I had intended, if possible, to bring this very matter before the British Association at its next meeting, believing that a select Committee of the Association would best be able to further the interests of marine zoology in this respect But, as the matter now stands, I leave any such action very willingly to Prof Herdman's initiative.

Put broadly (although I well know that such a work in Prof. Herdman's hands would by no means have the character of a mere compilation), the question at issue is whether the handbook should be mainly a compilation from existing material, or should express the work of various specialists and be based upon a series of special investigations. For myself I agree with Prof Thompson, and for the same reasons, that the adoption of the latter alternative would be likely to meet our needs most fully and satisfactorily. It would ensure, as far as possible, the equal treatment of the various groups, and would thus give to the book (which is important) a more permanent and authoritative value than could be attained by a book depending upon the personal labours of one zoologist I feel confident that, should Prof Herdman admit the force of this consideration and be willing to edit a handbook in which the diagnoses were drawn up for the various groups by specialists or specially chosen investigators, he would find no difficulty whatever in meeting with willing co-operation

But I hardly see the point of extending the scope of the work to the extent which Prof Thompson would seem to desire We need a handbook for use around the coasts of our own islands To include the fauna of the whole North Atlantic would needlessly add to the size of the work, delay the time of its appearance, and even in the end be incomplete, while it is doubtful whether the advantages would at all outweigh these defects W GARSTANG

Marine Biological Association, Plymouth, January 20

Fossil Plants as Tests of Climate

MR. J. STARKIE GARDNER, in his interesting review of Mr. Seward's valuable essay, makes a statement which I fancy may be misinterpreted at page 268 of NATURE, where he speaks of the fragmentary character of the Arctic tertiary plants, and the inexperience of the collectors He doubtless is referring to the remains of certain supposed "palms and cycads in the Greenland Eocene," but those who have not followed this branch of Arctic research would hardly gather from the review that Prof Heer has determined a magnificent flora of more than 350 species from these northern tertiaries, and that he at once pointed out the absence of tropical and subtropical forms, and the fact that large leaves are not only perfectly preserved up to their edges, but that upright trees associated with their fruits and see is prove them to have grown on the spot "Thus of *Sequoia Langsdorffi*," he writes, "we see not only the twigs covered with leaves, but also cones and seeds, and even a male catkin "[1]

In April 1875 I endeavoured to give an abstract of all that was then known of Arctic geology, in a series of articles that appeared in your columns (NATURE, vol xi pp 447, 467, 492, and 508), and added some general conclusions of my own, which are further accentuated in the joint communications of Colonel Feilden and myself to the Geological Society in 1878, and in the "Geology Appendix" to Sir George Nares' "Voyage to the Polar Sea,' in which expedition Colonel Feilden played a most valuable part I have ever since carefully followed the progress of Arctic research, and am now of opinion that looking to the identity of a large number of species (often extending to the varieties of the same) occurring in the Silurian, Carboniferous, Lias, Oolite, Cretaceous, and Tertiary strata of the Arctic regions, with those occurring in similar strata in Europe and other parts of the world, they point to a common temperature over these areas and probably over the whole world, from Silurian to early Cretaceous times, and that this was the case does not appear to me to be affected by the question as to whether or not these deposits were homotaxeous

In late Cretaceous times commenced *horizontal* variation of cold, or what we now term "climate," though previously *vertical* variation had evidently been present, for the later investigations of Messrs. Blanford appear to place beyond doubt the existence of glaciers in geological times, as was suggested in 1855 by my lamented chief, Sir Andrew Ramsay, but I equally fail to see that the slightest evidence has been anywhere adduced to support the theory of "recurrence of ice-ages," originated by my talented colleague the late Dr Croll, and now supported with a "modification" by Sir Robert Ball.

The facts, whether we look to the history of plant life, or animal life, or the character of the rocks themselves, appear to me to be all the other way, as they disclose nothing resembling the refrigeration that, gradually increasing in the Tertiary epoch, culminated in the Glacial episode, which choked up the North and Irish Seas with an ice-sheet since man has been an occupant of our islands CHAS. E DE RANCE.

Racial Dwarfs in the Pyrenees.

IN consequence of evidence that I had obtained as to the existence of a dwarf race in Spain, I wrote to Mr. McPherson,

[1] "On the Miocene Flora of North Greenland," by Prof Oswald Heer, Translated by R H Scott, F R.S, Brit Assoc, 1867, pp. 53

our Consul at Barcelona, and enclose his reply There have long been rumours of survivals of a dwarf or a prehistoric race existing in parts of Spain, but careful inquiries at Madrid failed to supply any definite information on the subject Last summer on reading over an old number of *Kosmos* (Paris, 1887), I found a brief paragraph referring to a pigmy race having been found in the province of Gerona, Spain, who had slightly Mongolian eyes, yellow, broad, square faces, height from 1 m 10 to 1 m 15, and red hair

An Austrian gentleman recently told me he had seen, in the market-place at Salamanca, some very under sized peasants, with broad faces and mahogany-coloured woolly hair

You will see that these accounts all agree substantially, and that these dwarfs and those of Africa are precisely similar

I have got a deal of information from an old Spanish woman who belongs to a half breed nano family, and who says that there are in such families frequently nanos (or "enanos") who have red tufts of wool, and are as small as ordinary small boys But these tufts of wool are peculiarly characteristic of dwarf races nearly everywhere

I shall write more fully as to my inquiries among half breed nanos, but they are of very secondary interest now that we can find pure racial nanos within easy reach

It is most fortunate that they live in the Valley of Ribas and the Col de Tosas, within a little more than a half-day's journey from Toulouse Some health-seekers or tourists in the South of France may perhaps feel inclined to pay a visit to these little people

Should the suggestion be acted on, and prove satisfactory, a line to myself on the subject, addressed to 28, Pall Mall, would be highly valued R G HALIBURTON

Tangier, January 9

[COPY]

"*British Consulate, Barcelona, December* 10, 1892

"DEAR SIR,—Since I received your letter of November 18 and its enclosures I have endeavoured to ascertain what truth there is in the statement that pigmies, or 'enanos' (not 'nanos') exist in the Valley of Ribas From conversations I had with various individuals who have visited that district it appears certain that a race of men, of about from one metre to one metre and twenty centimetres high, of a darkish complexion (copper-coloured), dark hair and woolly, and flat, broad nose, live in that district, particularly in the 'Collado de Tosas.' They are active, and are generally employed as shepherds. It is also asserted that they are not very intelligent, and that they appear to understand and to make themselves understood with difficulty It would be an easy journey to go to that place from this town. I had no little difficulty in finding out that such a race lived in that place, for many of the persons with whom I have spoken on the subject were evidently confused and confused me, as besides these, evidently racial pigmies, there are in that neighbourhood many 'cretins,' which were at times described to me as if these were the 'enanos' I spoke about I am now certain that there are cretins and pigmies in the Valley of Ribas. It is stated that the 'enanos' are rapidly disappearing, and that latterly many have died of smallpox The men you speak of, who were seen at Salamanca, are, I should say, natives of the Batuecas, or rather of Los Hurdes. These men were discovered in the sixteenth century, and they were then and are even now, in an almost absolute state of savagery" [The remainder as to this race is omitted, as it does not appear that they are nanos.—R G H.]

"Yours very truly,

(Signed) "WM MCPHERSON.

"R G Haliburton, Esq"

British Earthworms

I WRITE to suggest—in connection with the recent letters in NATURE upon this subject—that some one give a thoroughly trustworthy list of British earthworms, with the memoirs in which the species were originally described, and the chief characteristics of each. Dr. Benham would be doing very useful and acceptable work if he were to accomplish this. From what I understand everybody has been making mistakes, and the whole matter is in the utmost confusion. It is very necessary that such a classification should exist, if only for the benefit of those who are working on the earthworm more from a comparative anatomist's than from a specialist's point of view

DANTE'S "QUÆSTIO DE AQUA ET TERRA."

"Quæstio Aurea ac perutilis edita per *Dantem Alagherium*, poetam florentinum clarissimum, de natura duorum elementorum Aquæ et Terræ disserentem"

"Lo, the past is hurled
In twain up thrust, out staggering on the world,
Subsiding into shape, a darkness rears
Its outline, kindles at the core, appears
Verona"—R BROWNING, "Sordello," Book i

"TO all and each who shall see this document, *Dante Alighieri* of Florence, the least amongst true philosophers, wishes health in Him who is the Beginning of truth and the Light

"Be it known unto ye all that whilst I was at Mantua there arose a certain question, the which after having been many times dilated upon rather for vain show than for Truth's sake, still remained undecided Wherefore I, since from boyhood I have been nurtured continually in love of Truth, could not bear to leave the question undiscussed, but I thought fit to show the truth concerning it and to dissolve the arguments adduced to the contrary, both for love of Truth and hatred of Falsehood And lest the malice of many who are wont to fabricate envious lies against the absent should behind my back alter what was well said, I have moreover thought fit to leave written down on paper what I proved, and to set forth the form of the whole disputation"

These are the words with which Dante commences this "golden and most useful" inquiry concerning the nature of the two elements, earth and water The treatise is little known in comparison with the other writings of the poet,[1] but although rejected by Ugo Foscolo and others as "impostura indegna d'esame," its genuineness and importance are now almost universally admitted, and without yielding unreservedly to the enthusiastic opinion of an Italian geologist (Stoppani) that there are more truths relating to cosmology to be found prognosticated, affirmed, and even demonstrated in these few pages of the supreme poet than in all the writings of the middle ages taken together, we may nevertheless acknowledge it to be a work of the greatest interest and importance, and by no means unworthy of the singer of the "Divina Commedia"

It seems to be the last work of the poet's life, written at that period which he himself describes in his sonnet to Giovanni Quirino —

"Lo Re, che merta i suoi servi a ristoro
Con abbondanza, e vince ogni misura,
Mi fa lasciare la fiera rancura,
E drizzar gli occhi al sommo consistoro
E qui pensando al glorioso coro
De' cittadin della cittade pura,
Laudando il Creatore, io creatura
Di più laudarlo sempre m'innamoro"
—Sonetto xliv ed. Fraticelli[2]

Dante was at this time the guest of Guido Novello di Polenta at Ravenna. About the commencement of the

[1] It is, I believe, the only one of Dante's writings that has not yet been translated into English.

[2] "The King by whose rich grace His servants be
With plenty beyond measure set to dwell,
Ordains that I my bitter wrath dispel
And lift mine eyes to the great consistory
Till, noting how in glorious quires agree
The citizens of that fair citadel,
To the Creator I, His creature swell
Their song, and all their love possesses me"
—Rossetti's translation in "Dante and his Circle"

year 1320, he seems to have gone for some unknown reason to Mantua, and there to have entered upon this discussion, which he then completed at Verona. The disputation took place at this latter city on January 20, 1320, as Dante himself tells us, in the church of St Helena (where in recent years the metropolitan chapter have put up a monument in commemoration of the event). All the clergy of Verona were present, except some few who, in the words of Rossetti—

> "Grudged ghostly greeting to the man
> By whom, though not of ghostly guild,
> With Heaven and Hell men's hearts were fill'd."
> —"Dante at Verona."

From a passage which occurs in the course of the treatise, one might almost think that ladies also were present, but let not the reader therefore conclude that the assemblage which listened to Dante's eloquence in that little Veronese temple resembled so many modern philanthropical and other associations in being chiefly composed of ladies and clergymen, for doubtless Can Grande della Scala himself was present to do honour to his former guest, and his poetic fame, which we know to have already spread far and wide, would certainly have brought together as many as the church could hold.

The question to be solved is whether, on any place on the earth's surface, *water* is higher than the *earth*. This question, Dante tells us, was generally answered in the affirmative, and he gives us the five chief reasonings adduced in support of it, of which perhaps the most striking is this one:—

"If the earth were not lower than the water, the earth would be entirely without waters, at least in the uncovered part, and so there would be no fountains, nor rivers, nor lakes. So water must be higher than the earth. For water naturally flows downwards, and the sea is the source of all waters, and if the sea were not higher than the earth, the water would not flow to the earth, since in every natural motion the source of the water must be higher."

Another is this:—"Water seems chiefly to follow the motion of the moon, as is evident in the flow and ebb of the sea, and therefore since the moon's orbit is eccentric, it seems reasonable that water in its sphere should be eccentric too; and another argument shows that this cannot be unless it be also higher than the earth."

Such be their arguments, but sense and reason alike are against them, and Dante proceeds to explain how he will treat the question. First, he will prove that it is impossible that water in any part of its circumference be higher than this emergent or uncovered earth on which we dwell. Secondly, he will prove that this emergent earth is everywhere higher than the surface of the sea. Thirdly, he will urge arguments against his own demonstrations, and then demolish these objections. Fourthly, the final and efficient cause of the elevation and emergence of the earth will be shown. Fifthly, he will demolish the five chief arguments of the other side which he has already stated.

1. It is impossible that water in any part of its circumference be higher than the earth.

There are only two ways whereby water can thus be higher than the earth: either the water must be *eccentric*, or, if it be *concentric* with the earth, it must be *gibbous* in some part. By water being *eccentric*, Dante means the centre of its natural sphere to be out of and different from the centre of the earth; by being *gibbous*, Dante means some part of its sphere to be raised up so as to form a protuberance or hump, just as he considers the earth on which we live to be a protuberance or gibbosity of the spherical surface of the earth.

He now shows by means of diagrams that neither of these things are possible, but first makes these two statements—(1) Water naturally flows downwards; (2) Water is by nature a labile body and has not a boundary of its own, but takes the boundary of the thing in which it is contained.[1]

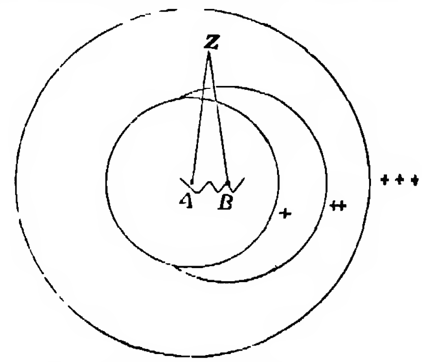
We may compare with this a modern definition of a fluid:—

"A perfect fluid is a body whose form can be changed to any extent, provided its volume remain constant, by the application of a stress, however small, if we allow it sufficient time."—Garnett, "Treatise on Heat."

In the first place, *water cannot be eccentric.*

For if it were so, then three impossibilities would follow—(1) Water would naturally flow both upwards and downwards; (2) water would not be moved downwards by the same line as the earth; (3) an equivocation would arise in speaking of the *gravity* of water and of earth; all which things are seen to be not only false but impossible.

The demonstration *ab absurdo* follows thus:—Let the heavens be the circumference on which are placed three crosses, water the circumference on which are two, earth the circumference on which is one cross.



Let the centre of heaven and earth be at point A, the centre of water at point B. Thus A, being the centre of the universe, is the lowest spot of all, and everything which has in the world a position alien from A must be higher. Now if there be any water at A and the way be open to it, it will naturally flow to its own centre, B, since it is the property of every heavy body to move to the centre of its own sphere. But the motion from A to B is a motion upwards; therefore water will flow *upwards*, which is impossible.

Again, let there be at Z a lump of earth and some water, and let there be nothing to hinder. Then, since it is the property of every heavy body to move to the centre of its own sphere or circumference, the *earth* will move in a straight line to A, and the *water* in a straight line to B, and this, from the figure, must needs be along different lines. This, says Dante, is not only impossible, but would make Aristotle laugh if he were to hear it.

The third impossibility follows thus:—*Gravity* and *levity* are "passions" of simple bodies which are moved with linear motion, and *light* bodies tend upwards and *heavy* tend downwards, by "heavy" and "light" being meant that which has the power of being moved. If now water moved to B and earth to A, since these are simple bodies and heavy, they will be moved down to different centres. If this were so, the word *gravity* would have an *absolute* signification with respect to earth and *relative* with respect to water. This is what the argument amounts to, and so there would be an equivocation of meaning in the word "gravity."

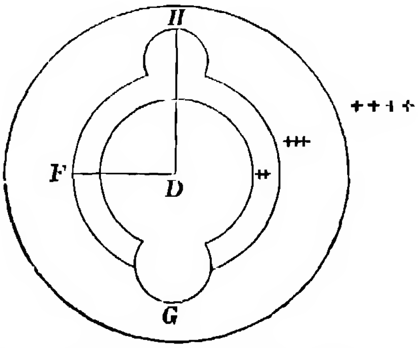
Therefore, *ab absurdo*, water in its natural circumference is not eccentric or out of the centre common to the circumference of the earth.

In the second place, *water cannot be gibbous*.

[1] "Aqua est labile corpus naturaliter, et non terminabile termino proprio."—§ xi.

Let the heavens be where are four crosses, the water where three, the earth where there are two.

Let D be the centre of *earth* and concentric *water* and *heaven* Water cannot be concentric with the earth unless the earth be in some part "gibbous" above the central circumference Let the protuberance of the earth be at G, and at some part of the circumference of water let there be a protuberance of water at H Then let a line be drawn from D to H and another from D to F, it is manifest



that D H is longer than D F, and therefore the summit of one is higher than the summit of the other Since both touch at their summit the surface of the water without passing beyond, it is clear that the water of the protuberance will be higher, with regard to the surface where F is Since, therefore, there is no obstacle, the water of the protuberance will flow down until it become level at D with the central or regular circumference And thus it will be impossible for a protuberance of water to last or even to exist.—Q E D

Dante now brings forward a subsidiary argument to show that probably water has no protuberance out of the regular circumference The protuberance of the earth is sufficient to prove and explain everything, and "Quod potest fieri per unum, melius est fieri per unum quam per plura." So there is no protuberance on the surface of the water, because God and Nature always do what is best and do not work in vain

Since water cannot be eccentric, as was shown by the first figure, nor concentric with a protuberance, as was shown by the second figure, it is necessary that water be concentric and coequal, *i e* equally distant in every part of its circumference from the centre of the world

Thus it has been proved impossible for water in any part of its circumference to be higher than the surface of the earth, and so the first point is completed

We now pass on to the second.

2 This emergent earth is everywhere higher than the surface of the sea This is shown in this way.—

All the shores of the ocean, as well as of the Mediterranean seas, rise above the surface of the sea which bounds them, as is clear to the eye Therefore all the shores are further from the centre of the world, since the centre of the world is also the centre of the sea and the shoreward surfaces are parts of the whole surface of the sea; and since everything that is more remote from the centre of the world is also more high, it follows that the shores everywhere rise above the surface of the sea. And if the shores are higher than the sea, much more must be the other regions of the earth, since the shores are the lower parts of the earth, as we see by the rivers flowing down to them

3. In accordance with the order of the question as at first stated by Dante, he now brings forward various arguments which seem to contradict his demonstrations, and these arguments he then proceeds to demolish They need not detain us here. In the course of the operation there occurs a most interesting distinction between *homogeneous* and *simple* bodies, in which I seem to see a distinct foreshadowing of our modern view of the chemical elements in contradistinction to the ordinary four or five elements of Aristotle and his followers "Corpora enim homogenea et simplicia sunt, *homogenea ut aurum depuratum*, et corpora simplicia, ut ignis et terra" § xviii

But perhaps it might not be out of place to quote here the following passage from G H Lewes's "Aristotle" —"One of the great difficulties in interpreting ancient opinions is to guard against the tendency of reading our fulness of knowledge into their vague expressions We often find in ancient works the precious metal we have ourselves brought with us, as the alchemist often unconsciously put into his crucible the gold, which he afterwards discovered there with surprised delight"—G H Lewes, "Aristotle," x § 170

He thus sets forth the *final* cause of the elevation or emergence of the earth There must needs be a part in the universe where all *miscibilia*—to wit, elements—can come together, this cannot be unless the earth be in some part emergent Thus, although earth, according to its own nature, tends always downwards, it has in it another nature by which it obeys the intention of Universal Nature, and allows itself to be here and there raised up, in order that mixture of the elements may be possible, and thence all things that are subject to generation and corruption may be formed

He further shows that the emergent earth on which we dwell has the form of a semilune, by arguments which he graciously tells us that even ladies can follow—"Manifestum esse potest etiam mulieribus"

4 What now is the *efficient* cause of the elevation or emergence of the earth above the surface of the water?

Dante first shows that neither the *earth* itself, nor *water*, nor *air*, nor *fire* can be the efficient cause Therefore it must be referred to the *heavens* But there are many heavens, and to which are we to refer it? Dante shows that it cannot be referred to the *moon*, nor to the heavens of any of the planets (Mercury, Venus, the Sun, Mars, Jupiter, Saturn), nor yet to the Crystalline Heaven or *Primum Mobile*, the 9th sphere Now, since the only mobile bodies which remain are the Heaven of the Stars, *Cœlum Stellatum*, or 8th circle, we must refer the cause of the elevation of the earth of our hemisphere to that This Heaven of the Stars has at once unity in substance and multiplicity in its virtues or influences, as the poet himself sings —

"Il ciel, cui tanti lumi fanno bello,
Dalla mente profonda che lui volve
Prende l'image, e fassene suggello
E come l'alma dentro a vostra polve,
Per differenti membra, e conformate
A diverse potenzie, si risolve,
Così l'intelligenzia sua bontate
Multiplicata per le stelle spiega,
Girando se sovra sua unitate."
—"Paradiso," ii 130 138 [1]

Dante further refers the elevation of our earth to that region of the Cœlum Stellatum which roofs over this uncovered earth, that is, that this elevating virtue or influence is in those stars which are in the region of the heaven, which is bounded by the equator and the circle which the pole of the zodiac describes around the pole of the world; "whether it elevate by way of attraction as

[1] "The heaven, which lights so manifold make fair,
From the Intelligence profound, which turns it,
The image takes, and makes of it a seal.
And even as the soul within your dust
Through members different and accommodated
To faculties diverse expands itself,
So likewise this Intelligence diffuses
Its virtue *multiplied* among the stars,
Itself revolving on its *unity*"
"Paradiso," ii 130–138, Longfellow's trans

the magnet draws the iron, or by way of impulsion, generating impelling vapours, as in certain mountains." A truly scientific and most suggestive remark!

We may compare the last clause with those well-known lines of the "Inferno," in which is described how the earth, and likewise the mountain of Purgatory were formed when Lucifer fell from Heaven:—

> "Da questa parte cadde giù dal cielo ,
> E la terra, che pria di qua si sporse,
> Per paura di lui fe del mar velo,
> E venne all'emisperio nostro e forse
> Per fuggir lui, lasciò qui il luogo voto
> Quella ch'appar di qua, e su ricorse."
> —"Inferno," xxxiv 121–126[1]

But now it may be asked, Since that region of the heaven moveth circlewise, why did not this elevation happen circlewise? Because, Dante answers, the matter was not sufficient for so great an elevation. Then why was the elevation of the earth produced in our hemisphere rather than in the other? To this, says Dante, we must answer as Aristotle does (in "De Cœlo," book ii) in answer to the question why the heavens move from east to west and not contrariwise, that such questions proceed either from much folly or from much presumption, because they are above our intellect. God made all things for the best, and when He said, "Congregentur aquæ in locum unum et appareat arida," then were the heavens virtuated to act and the earth potentiated to be passive.

"Let therefore men cease," cries Dante, "yea, cease from inquiring into those things which are above their intellect, and let them strive to the utmost of their power to raise themselves to things immortal and divine, and so leave those things which exceed their understanding. Let them listen to Job:—'Numquid vestigia Dei comprehendes, et omnipotentem usque ad perfectionem reperies.'—(Job xi. 7). Let them hearken to the words of the Psalmist: 'Mirabilis facta est scientia tua, et me confortatus est, et non potero ad eam.'—(Ps cxxxviii). Let them hear Isaiah speaking in the person of God to man: 'Quam distant cœli a terra, tantum distant viæ meæ a viis vestris.'—(Is lv 9). Let them hear the voice of the Apostle to the Romans: 'O altitudo divitiarum scientiæ et sapientiæ Dei! quam incomprehensibilia judicia ejus, et investigabiles viae ejus!'—(Rom. xi. 33). Lastly, let them hearken to the very voice of the Creator, saying: 'Quo Ego vado, vos non potestis venire.'—(S John vii. 34). And let these things suffice for the inquiry of the truth before us."

We may most fittingly compare this Dantesque passage with the close of Galileo Galilei's famous "Dialogo intorno ai due massimi sistemi del mondo, tolemaico e copernicano," which I here venture to translate:—

"*Simplicio.* If either of you were asked, If God in His infinite power and wisdom could confer upon the element of water the reciprocal movement which we perceive in it, in another way than by the moving of the vessel containing it, I know that you would answer, that He could have done so in many ways, even unimaginable by our intellect; whence I immediately conclude that, this being so, it would be excessive daring for any one to wish to limit and restrict the Divine power and wisdom to a particular phantasy of his own.

"*Salviati.* An admirable and truly angelical doctrine, to which very conformably answers that other divine doctrine, which, whilst it allows us to dispute about the constitution of the world, adds (perhaps in order that the exercise of human minds be not suppressed nor grow lazy) that we are not to find out the work of His hands. Let therefore the exercise permitted and ordained to us by God make us recognize and so much the more wonder at His greatness, as we find ourselves the less competent to penetrate into the profound abysses of His infinite wisdom.

"*Sagredo.* And this will serve for the last conclusion of our four days' argument."—Galileo Galilei, "Dialogo dei Massimi Sistemi, Giornata quarta."

Dante now briefly deals with the five arguments which he mentioned at the beginning of his treatise as the most important against his theory. These being made short work of, he concludes:—

"This philosophical question was determined by me, Dante Alighieri, the least of philosophers, beneath the sway of that invincible lord, Messer Cane Grande della Scala, for the holy Roman empire, in the illustrious city of Verona, in the church of S Helena, and in the presence of all the Veronese clergy, save some few who, aflame with too much charity, do not admit the postulates of others, and through virtue of humility poor of the Holy Spirit, shun being present at their discourses, lest they may seem to approve their excellence.

"Now this was done in the year from the Nativity of our Lord Jesus Christ, 1320, on Sunday, which the Saviour enjoined on us to venerate for His glorious Nativity and His wondrous Resurrection. The which day was the 7th from the ides of January and the 13th before the calends of February" (*i e* January 20).

I have dealt merely with the chief parts of this Dantesque dissertation. According to Signor A Stoppani ("La questione dell' Acqua e della Terra di Dante Alighieri," in "opp. Lat di Dante," ed Giuliani, vol ii) there are nine truths relating to cosmology, presaged, affirmed, and in part demonstrated. These nine he makes out thus:—

(1) The moon the principal cause of tides.
(2) Equality of the sea's level.
(3) Centripetal force.
(4) Sphericity of the earth.
(5) Dry land simply protuberance of the earth's surface.
(6) Northern grouping together of the continents.
(7) Universal attraction.
(8) Elasticity of vapours a motive power.
(9) Heaving up of the continents.

Let me now add a tenth: A vague foreshadowing of our modern idea of chemical elements as distinct from those of Aristotle, or at least of homogeneous chemical bodies; "Corpora enim homogenea et simplicia sunt; homogenea, ut aurum depuratum; et corpora simplicia, ut ignis et terra."

EDMUND G GARDNER

Caius College, Cambridge

[1] "Upon this side he fell down out of heaven;
And all the land, that whilom here emerged,
For fear of him made of the sea a veil,
And came to our hemisphere; and peradventure
To flee from him, what on this side appears
Left the place vacant here, and back recoiled."
—"Inferno," xxxiv. 121–126, Longfellow's trans.

MOROCCO.[1]

MOROCCO has a paradoxical place in the history of exploration; although the only part of Africa fully in sight from the shores of Europe, and dotted with one or two half European coast towns, its interior is more firmly closed to the traveller, sportsman, and missionary than the dense forests of the Congo, or even the shores of Lake Chad. The difficulties in the way are not physical, nor are they wholly political. They arise mainly from the deeply-rooted antagonism in race and creed between the inhabitants of Morocco and all Christendom—this quaint and semi-fossil phrase is still here a necessary and sufficient term. At this moment public atten-

[1] "Bibliography of the Barbary States." Part IV. A Bibliography of Morocco from the earliest times to the end of 1891. By Lieut. Col Sir R Lambert Playfair and Dr Robert Brown.

tion is turned somewhat intently on the political conditions of the Oriental despotism which has so anomalously maintained itself to the west of our prime meridian. Hence the politician has a temporary interest in what would otherwise have appealed mainly to the geographer and man of science, the publication by the Royal Geographical Society of a "Supplementary Paper," the "Bibliography of Morocco." This is a work of splendid thoroughness, almost, if not quite, exhaustive in its list of 2243 titles, and made convenient for reference by two copious indexes of subjects and authors. But it is much more than a catalogue. Comments, judiciously brief, but in some cases of exceptional interest extending to a couple of pages, give information as to little-known authors, or record some striking circumstance in or concerning the books referred to. There is a specially-compiled map, and an introduction which is really an essay on the growth of knowledge regarding Morocco in European countries. With regard to the map, it is explained that only the coast-line has been surveyed. As to the interior:—

"The best mapped districts are laid down solely from running *reconnaissances* or sketch-maps. Positions fixed by astronomical observations are few. Many wide areas have never been visited by any Europeans, and most of the Atlas is at this hour as little known as it was in the days of Leo Africanus. There are cities within a few hours' ride of Tangier, which no person capable of giving a correct account of his observations has visited, and there are others not much farther away, to attempt to enter which—Zarhoun, for example—would, were the intruder detected, be certain death. There is scarcely a river laid down with even approximate accuracy, and, not to enumerate more distant provinces, the entire Riff country, that bold *massif* which is familiar to the thousands who every year sail up and down the Mediterranean, is less explored than many regions in the centre of the continent."

The present population of Morocco is a puzzle almost as difficult, although on a smaller scale, as that of China. The authors of the Bibliography give 4,000,000 as an estimate, but the guesses of various authorities vary between 1½ and 15 millions. The roads shown on the map are mere mule and camel tracks made by the feet of the pack-animals, unaided by any engineer. Ferries are rare, and, of course, bridges are unknown in the interior. The distribution of towns and villages is often at variance with the rules holding for civilised countries. The villages are built out of the way of the main tracks, because people never travel in Morocco for the good of the inhabitants, and it is safer to live off the path of the tax-collector and the Government official, who demands free food and quarters. The great number of place-names on the map of so thinly-peopled a country is due to the fact that the tombs of saints are such important landmarks that they must be indicated, even if only a few persons live beside them. "All the places beginning with 'Sidi' (Lord, master) are either actually tombs or the tomb has formed, as in so many of our cathedral cities, the nucleus of the town or village." "Sok," another affix of frequent occurrence, means market-place, and many of the established sites for periodical fairs are uninhabited between the gatherings of people from far and near. Many of the place-names on the coast exist in two forms at least—the native word and its Portuguese or Spanish translation, Casablanca and Dar-el-beida (both meaning White house) for example. We regret that the authors did not see their way to lay down precise rules for the spelling of Moorish place-names, either by giving a standard transliteration of the Arabic, or a uniform phonetic system. Indeed, even in the introduction a few anomalous spellings are found, *e.g.* *Zarhoun* and *Zerhun*, *Moulai* and *Mowlas*.

The physical geography of Morocco appears to be changing, and the natural conditions of the country are less favourable for agriculture than they were a few centuries ago. The forests have been destroyed with such recklessness that the soil has been dried up and swept away in many places; there is evidence that the rainfall has diminished, lakes have dried, and rivers formerly navigable have become silted up, or alternate as dry tracts of stone and raging torrents.

In one respect alone—the enthusiastic Moslemism of its people—does Morocco show no sign of degeneration. Although the Moors can no longer seize and hold the Christian slaves, whose stories bulk so largely in the bibliography, their hatred and contempt towards "unbelievers" is in no sense abated. Into such a land no Europeans could penetrate far, except in the past as slaves, or now as official messengers of European Powers under special protection, jealously watched and prevented from studying places or people. The last serious attempt at scientific exploration—that of Mr. Joseph Thomson—was again and again almost stopped by the fanatical Kaids, and only his remarkable persistence and daring stratagems carried him as far as he reached. Such stratagems would hardly serve again, and for the present the exploration of the Atlas Mountains, with their half-guessed topography, imperfectly known flora, and unsurveyed mineral wealth is at an end. The futility of disguise as an aid to exploration is fully proved in the records before us, where the ghastly fate of many who tried to pass as Moslems, and the unsatisfactory results obtained by others who escaped alive, are briefly told.

It seems to us that an attempt might well be made to open communications with fanatical Mohammedan countries either by explorers or diplomatic agents of the same faith, and there must be many amongst the educated Mohammedans of India who are well suited for such work. The religious beliefs of a people with whom belief and conduct are so closely related, must be taken into account in dealing with them, just as much as the physical features of a country. And as Arctic sailors have been proved to be the natural explorers in the Antarctic seas, Swiss mountaineers the safest pioneers on New Zealand glaciers, and Canadian boatmen the most expert in shooting the Nile cataracts, so Mohammedan envoys might be expected to make the most favourable impression on the people of Morocco or of the Mohammedan Sudan.

Sir Lambert Playfair and Dr. Brown deserve the heartiest thanks for completing their Bibliography of the Barbary States in such an admirable way, and we do not doubt that the work will be very widely consulted in the immediate future.

THE RATE OF EXPLOSION IN GASES

THE following is an abstract of the Bakerian Lecture on "The Rate of Explosion in Gases," delivered before the Royal Society by Prof. Harold B. Dixon, on January 19:—

1. Berthelot's measurements of the rates of explosion of a number of gaseous mixtures have been confirmed. The rate of the explosion wave for each mixture is constant. It is independent of the diameter of the tube above a certain limit.

2. The rate is not absolutely independent of the initial temperature and pressure of the gases. With rise of temperature the rate falls; with rise of pressure the rate increases; but above a certain *crucial pressure* variations in pressure appear to have no effect.

3. In the explosion of carbonic oxide and oxygen in a long tube, the presence of steam has a marked effect on the rate. From measurements of the rate of explosion with different quantities of steam, the conclusion is drawn that at the high temperature of the explosion wave, as

well as in ordinary combustion, the oxidation of the carbonic oxide is effected by the interaction of the steam.

4. Inert gases are found to retard the explosion wave according to their volume and density. Within wide limits an excess of one of the combustible gases has the same retarding effect as an inert gas (of the same volume and density), which can take no part in the reaction.

5 Measurements of the rate of explosion can be employed for determining the course of some chemical changes.

In the explosion of a volatile carbon compound with oxygen, the gaseous carbon appears to burn first to carbonic oxide, and afterwards, if oxygen is present in excess, the carbonic oxide first formed burns to carbonic acid

6 The theory proposed by Berthelot—that in the explosion wave the flame travels at the mean velocity of the products of combustion—although in agreement with the rates observed in a certain number of cases, does not account for the velocities found in other gaseous mixtures

7 It seems probable that in the explosion wave—

(1) The gases are heated at *constant volume*, and not at *constant pressure*,

(2) Each layer of gas is raised in temperature *before* being burnt,

(3) The wave is propagated not only by the movements of the burnt molecules, but also by those of the heated but yet unburnt molecules,

(4) When the permanent volume of the gases is changed in the chemical reaction, an alteration of temperature is thereby caused which affects the velocity of the wave.

8 In a gas, of the mean density and temperature calculated on these assumptions, a sound wave would travel at a velocity which nearly agrees with the observed rate of explosion in those cases where the products of combustion are perfect gases

9 With mixtures in which steam is formed, the rate of explosion falls below the calculated rate of the sound wave But when such mixtures are largely diluted with an inert gas, the calculated and found velocities coincide. It seems reasonable to suppose that at the higher temperatures the lowering of the rate of explosion is brought about by the dissociation of the steam, or by an increase in its specific heat, or by both these causes

10. The propagation of the explosion wave in gases must be accompanied by a very high pressure lasting for a very short time The experiments of MM Mallard and Le Chatelier, as well as the author's, show the presence of these fugitive pressures It is possible that data for calculating the pressures produced may be derived from a knowledge of the densities of the unburnt gases and of their rates of explosion.

NOTES.

THE forty-sixth annual general meeting of the Institution of Mechanical Engineers will be held on Thursday evening and Friday evening, February 2 and 3, at 25, Great George Street, Westminster. The chair will be taken by the president, Dr. William Anderson, F R S, at half past seven on each evening. The annual report of the council will be presented to the meeting on Thursday, and the annual election of the president, vice-presidents, and members of council, and the ordinary election of new members will take place on the same evening The following papers will be read and discussed, as far as time permits:—Description of the Experimental Apparatus and Shaping Machine for Ship Models at the Admiralty Experiment Works, Haslar, by Mr. R. Edmund Froude, of Haslar (Thursday); description of the Pumping Engines and Water-Softening Machinery at the Southampton Water Works, by Mr. William Matthews, Waterworks Engineer (Friday)

PROF CAYLEY, we are glad to learn, is now convalescent.

WE greatly regret to have to announce the death of Mr H F Blanford, F.R.S. He died on Monday at the age of fifty-eight

PROF MICHAEL FOSTER, Sec R S, has been appointed Rede Lecturer at Cambridge for the present term. His Rede lecture will be delivered early in June

THE Bill for the introduction of a standard time (mean solar time of the fifteenth meridian) was read a second time in the German Imperial Parliament on Monday The measure was accepted without much discussion

AN excellent report on technical education in London has been submitted to the London County Council by a special committee appointed to investigate the subject. The report was prepared by Mr Llewellyn Smith, the committee's secretary, and displays a thorough grasp of the essential conditions of the problem It is proposed that a Technical Instruction Board shall be appointed, and that it shall consist of some members of the Council, and of representatives of the School Board, the City and Guilds of London Institute, the City Parochial Charities, the Head Masters' Association, the National Union of Elementary Teachers, and the London Trades Council The committee think that one third of the amount derived from the beer and spirits duties should be handed over to this body for the provision of adequate technical instruction in all parts of London

THE French Minister of the Interior has established at Marseilles, in connection with the university, an institute for botanical and geological research, and a museum The director is Prof Heckel, who, as well as a curator and a librarian, gives his services gratuitously

IN the year 1793 was published Christian Konrad Sprengel's "Das entdeckte Geheimniss der Natur, im Bau und in der Befruchtung der Blumen," the work which first directed the attention of naturalists to the contrivances which, in many flowers, render self-pollination difficult, and promote the visits of insects to assist cross-pollination The copper-plate illustrations of this work still maintain their character as among the best that have been published in this branch of science. Sprengel was in many respects a forerunner of Darwin, and centenaries have been celebrated on slighter grounds than the publication of this work

THE chief characteristics of the weather during the past week have been its general mildness and dampness, the day temperatures have at times exceeded 50° in most parts of the kingdom, but at night slight frosts occurred towards the end of last week in Scotland and the south-eastern parts of England. The distribution of pressure has been complex, a series of depressions have passed over the coast of Norway from the westward, while an anticyclone lay over the south-western parts of our islands, the reading of the barometer in the south-west being about an inch higher than in the north of Scotland. The passage of the low-pressure systems in the north was accompanied by strong north-westerly winds and gales in Scotland, with hail or sleet in many places. Owing to the disappearance of the anticyclone from the continent, north-westerly winds became prevalent over western Europe, and a rapid rise of temperature occurred there, amounting to 30° in Germany between the 20th and 21st instant During the last few days fresh depressions have approached our north-western coasts, with increasing winds from the south-west, and

a continuance of mild, unsettled weather appeared probable The *Weekly Weather Report* shows that for the week ending the 21st instant there was a large deficiency of rainfall in the west of Scotland, south-west of England, and south of Ireland. The percentage of possible duration of sunshine ranged from 28 in the south-west of England to 7 in the south of England and to 3 in the north of Scotland

THE *Repertorium fur Meteorologie*, vol. xv recently issued by the Imperial Academy of Sciences of St Petersburg, contains a discussion by P A. Muller, of the Ekaterinburg Observatory, at the foot of the Ural Mountains, in the Government of Perm, on the question of the evaporation from a snow surface Several writers, among whom are Drs Bruckner and Woeikof, differ in opinion as to whether the evaporation from a snow surface exceeds the condensation of the aqueous vapour of the air immediately above it The method generally adopted for the decision of the question is to find whether the temperature of the snow surface is above or below the dew-point of the surrounding air, in one case there would be evaporation, and in the other condensation The paper occupies forty seven small folio pages, and the observations were made hourly from December 21, 1890, to February 28, 1891 The result of the investigation shows that according to the temperatures of the dew-point and of the surface of the snow, the evaporation of the snow greatly exceeds the condensation of the aqueous vapour, for the condensation occurred at only 27 per cent while the evaporation occurred at 73 per cent of the hourly observations

PROF FLINDERS PETRIE, to whose introductory lecture at University College, Gower Street, we referred last week, delivered on Saturday the first of his regular course of lectures on the Edwards Foundation He said the Egypt of the early monuments was a mere strip of a few miles wide of green, amid boundless deserts, and beneath a sky of the greatest brilliancy, a land of extreme contrasts of light and shadow, of life and death These conditions were reflected in the art On the one hand was the most massive and overwhelming construction, and, on the other, the most delicate and detailed reliefs. On the one hand, the most sublime and stolid statuary, on the other, the course and accidents of daily life freely treated. On the one hand, masses of smooth buildings that far outdo the native hills on which they stand, gaunt and bare, and, on the other, the vivid and rich colouring in the interiors In consequence of the climate also Egypt is a land of great simplicity of life, and simplicity is especially the characteristic of the oldest Egyptian buildings Speaking of the early Egyptian statuer, Prof. Petrie said that the race represented by them appears as "one of the noblest that ever existed"

AT Leeds, on Monday, Lord Playfair presided at a public dinner, held in support of the Yorkshire College In proposing the principal toast—"The Yorkshire College"—he spoke of the efforts made half a century ago to secure for science the place which rightly belongs to it in the educational system. He was glad, he said, that these efforts had met with a temporary resistance, because if the Universities had at once yielded there would have been no colleges now in our great provincial towns The colleges, he thought, were adapting themselves rapidly and well, upon the whole, to the genius of their several localities Of the Yorkshire College he said that she had fitted herself for the liberal culture and life-work of a great industrial centre. "No doubt her technical courses are peculiar Actual laboratories for spinning, for dyeing, for tanning, for engineering, are novel adjuncts to a college. What does it mean? That you are trying to strengthen and embellish industrial pursuits, as the Universities acted upon the professions when they were obliged to include them. Surely a great town like Leeds is right when it imbues its producers with intellectual knowledge, as well as with technical expertness Such men in future carve out industrial professions for themselves, and illumine them by appropriate culture."

THE interesting address lately delivered by Sir Henry Roscoe on the occasion of the prize distribution at the Birmingham Municipal Technical School has now been issued separately. He describes the report of the first year's work as "more than encouraging." Speaking of the building which is to be erected for technical training at Birmingham, he says:—"You in Birmingham have, in my judgment, taken the right course. You are not going to squander your money by using it for a thousand different purposes You are, I hope, going to do a good thing, and a big thing, in building and equipping a really great institution, worthy of your city and of your well-earned renown as being foremost amongst our towns in educational matters You will have a place of higher technical instruction to which all the Midlands will look up It will be the gathering ground for all the youthful talent of the busy millions of the district It will be here that the future Faradays, and Priestleys, and Watts will get that sound though elementary scientific training which will enable them to pursue that training to its highest point at the Mason College here, or in other colleges elsewhere, which may in the end make both them and their country great"

THE new technical schools connected with University College, Nottingham, which were formally opened the other day, promise to be of immense service, not only to Nottingham itself, but to the wide district of which it is the educational centre A remarkably clear description of the buildings, with plans, is given in a pamphlet prepared for the ceremonial opening The pamphlet also includes an interesting summary of the facts relating to the history of the Nottingham College and its technical department

MR. C F JURITZ, Senior Analyst in the Department of Lands, Mines, and Agriculture, Cape Colony, announces in the *Agricultural Journal*, issued by the Department, that a comprehensive series of investigations with reference to the chemical composition of the various soils of the colony is about to be undertaken The samples of soil are to be collected by one of the officers of the analytical branch of the Department. In the first instance the southern part of the Malmesbury district will be visited, and soils will be taken from several localities representative (*a*) of primary and (*b*) of alluvial soils belonging to the Malmesbury beds of clay slate. Mr Juritz proposes next to collect soils from the more northerly portion of the same district, in the vicinity of Hopefield, for instance, after which the Caledon district will be taken in hand These analyses when completed will afford, he points out, an insight into the general composition of the clay slate soils, lying around the south-western coast of the Colony between Donkin's and Mossel Bays The Government of Cape Colony look upon the proposals that have been made as "a move in the right direction," and have promised their warmest support.

MR KEDARNATH BASU, describing in *Science* some relics of primitive fashions in India, says he does not see the same profusion as he saw ten or twelve years ago, of tattoo-marks and red-ochre or red oxide of lead (*sindur*) over the forehead and crown among the women of Bengal. The rapid progress of female education and the consequent refinement in æsthetic taste are, he says, the causes of the decline of this rude and savage adornment. The people of Behar, the North-western provinces, and other districts, however, still cling to these remnants of savagery. The up-country women, besides tatooing their bodies and painting the head with red paint, bore the lower lobes of their ears,

and insert big and heavy wooden cylindrical plugs, which almost sever the lobes from the ears. The plugs are sometimes as big as two inches in length with a diameter of an inch and a half, and as much as two ounces in weight These heavy plugs pull down the lobes of the ears as far as the shoulders, and give the wearers a hideous look

MR F J BLISS contributes to the new "Quarterly Statement" of the Palestine Exploration Fund a most interesting report on the excavations at Tell-el Hesy during the spring season of 1892 Speaking of the now famous tablet discovered in the course of these excavations, he says:—"On Monday, May 14, ten days before we closed the work, I was in my tent at noon with Ibrahim Effendi, when my foreman Yusif came in with a small coffee-coloured stone in his hand It seemed to be curiously notched on both sides and three edges, but was so filled in with earth that it was not till I carefully brushed it clean that the precious cuneiform letters were apparent Then I thought of a day, more than a year before, when I sat in Petrie's tent at the pyramid of Meydûm, with Prof Sayce He told me that I was to find cuneiform tablets in the Tell-el Hesy, which as yet I had never seen, and gazing across the green valley of the slow, brown Nile, and across the yellow desert beyond, he seemed to pierce to the core, with the eye of faith, the far away Amorite mound As for me, I saw no tablets, but I seemed to be seeing one who saw them!" Mr Bliss also notes that the discovery was a triumphant vindication of Mr Flinders Petrie's chronology—established, not by even a single dated object, but by pottery, mostly plain and unpainted It is announced in the "Quarterly Statement" that the excavations at Tell el Hesy are now being vigorously carried on by Mr Bliss, who has recovered from his serious illness

IT seems that in Yucatan and Central America, as in Egypt and other countries, ancient monuments are held in small respect by certain classes of travellers. According to Mr. M. H Saville, assistant in the Peabody Museum, who writes on the subject in *Science*, enormous damage is being done to many of the most interesting antiquities in these regions The magnificent "House of the Governor" in Uxmal, described as probably the grandest building now standing in Yucatan, is almost covered with names on the front and on the cemented walls inside These names are painted in black, blue, and red, and among them are the names of men widely known in the scientific world. The "House of the Dwarfs" in the same city has suffered in like manner, and many of the sculptures which have fallen from the buildings in Uxmal have been wilfully broken In Copan, when the Peabody Museum Honduras Expedition compared the condition of the "Idols" to day with the photographs taken by Mr A P Maudslay seven years ago, it was found that during that time some of the very finest sculptures had been disfigured by blows from machetes and other instruments. The Stela given as a frontispiece in Stephens' "Incidents of Travel in Central America," vol i., has been much marred by some one who has broken off several ornaments and a beautiful medallion face from the northern side One of the faces and several noses have been broken off from the sitting figures on the altar figured by Stephens in the same volume, opposite page 142, and on some of the idols and altars names have been carved. While excavating in one of the chambers of the Main Structure, members of the Expedition uncovered a beautiful hieroglyphic step, but before they had time to secure a photograph of it, some visitor improved the opportunity while no one was about to break off one of the letters. In Quirigua a small statue, discovered by Mr. Maudslay and removed by him to a small house near the rancho of Quirigua, had the head and one of the arms broken from it during the interval between two visits. This statue was of the highest importance, as it very much resembled the celebrated "Chaac-mol" now in the Mexican Museum, but discovered by Le Plongeon at Chichen Itza. Much mischief is also done by natives, who think nothing of tearing down ancient structures in order to provide themselves with building materials The authorities of the Peabody Museum, to whom the care of the antiquities of Honduras has been granted for a period of ten years, deserve much credit for the efforts they make to cope with the evil They have caused a wall to be built round the principal remains in Copan, and a keeper has been placed in charge with strict orders to allow nothing to be destroyed or carried away

WHAT is the true Shamrock? Most Irishmen are probably of opinion that they can answer the question correctly, but unfortunately they do not all give the same reply Mr Nathaniel Colgan, who has been investigating the subject, collected thirteen specimens from the following eleven counties—Derry, Antrim, Armagh, Mayo, Clare, Cork, Wexford, Wicklow, Carlow, Queen's County, and Roscommon Shamrocks were thus secured from northern, southern, eastern, western, and central Ireland, Mr. Colgan's correspondents in the various counties taking pains to have each sample selected by a native of experience who professed to know the genuine plant All the specimens were planted and carefully labelled with their places of origin, and flowering within some two months later gave the following results eight of the specimens turned out to be *Trifolium minus* of Smith, and the remaining five *Trifolium repens* of Linnæus Cork, Derry, Wicklow, Queen's County, Clare, and Wexford declared for *Trifolium minus*, Mayo, Antrim, and Roscommon for *Trifolium repens*, and Armagh and Carlow, each of which had sent two specimens, were divided on the question, one district in each county giving *T. repens*, while the other gave *T. minus* These results are set forth by Mr Colgan in an interesting paper in the first volume of the *Irish Naturalist*, to which we referred last week Elsewhere in the same volume Mr R L Praeger suggests that authentic specimens of shamrock should be obtained from every county in Ireland, and he adds that he has no doubt Mr. F W. Moore would gladly grow them at Glasnevin Gardens, if Mr Colgan did not care to undertake so large an order Mr Praeger notes that in his own district, North Down, *Trifolium minus* is always regarded as the true shamrock, but that a luxuriant specimen, or one in flower, is generally discarded as an impostor

THE waters of the Great Salt Lake, Utah, are known to vary in salinity at different times Dr Waller, of Columbia College, gives the results of his recent determination of the dissolved salts in the *School of Mines Quarterly* A comparison of his results with those obtained by Gale, Allen, Bassett, and others, shows a constant change of salinity, and a closer examination reveals a variation from place to place This is due to local differences in the amount of evaporation, and to the influx of water, fresh or saline, in many cases from subterranean springs which give no indication of their presence For some of the constituents the water is nearly at saturation point, and differences of temperature are also apt to cause slight differences of composition. The presence of lithium and bromine strengthens Captain Bonneville's conclusions with regard to the basin of the ancient lake called after his name, and now represented by the Great Salt Lake and its lesser neighbours The benches of sand and gravel seen high up on the flanks of the Wahsatch mountains and the Oquirrh range indicate the eastern and western shores of the old lake, whose waters must have covered an area equal to that of Lake Huron, or ten times that of the Great Salt Lake. Successive lowerings of level finally cut off its outlet to the north, by which it used to flow into the Pacific Ocean.

A BEAUTIFUL optical phenomenon, which has not yet been satisfactorily explained, is described by M F Folie in the *Bulletin* of the Belgian Academy It was observed about a mile from Zermatt on August 13 at 8 30 a m "On our right, towards the east, on the steep flanks of the mountains which enclose the valley of the Viège, rose a group of fir trees, the highest of which projected themselves against the azure of the sky, at a height of 500 m above the road Whilst I was botanising my son exclaimed 'Come and look the firs are as if covered with hoar-frost!' We paid the most scrupulous attention to the phenomenon To make sure that we were not misled by an illusion we made various observations, both with the naked eye and with an excellent opera glass" It was observed that not only the distant trees, but those lining the road, glittered in a silvery light, which seemed to belong to the trees themselves, and that the insects and birds playing round the branches were bathed in the same light, forming an aureole round the tops of the trees, somewhat resembling the light effects observed in the Blue Grotto It is suggested that the light was reflected from the snow Since it disappeared as soon as the sun rose above the hill, and has never been seen except in the presence of snow, this explanation appears plausible, but it is highly desirable that further and more detailed observations should be made of this *spectacle féerique*

THE Tasmanian Official Record is henceforth to be issued tri-annually instead of annually, and a handbook has been issued to take its place during the intervening years This hand book (which is described on the title-page as "for the year 1892") contains a brief epitome of the historical portion of the Official Record, and summarises in a convenient form the more important statistical information contained in the detailed tables of the last volume of the general statistics of the colony

MESSRS ASHER AND CO. will publish shortly an English translation of the "Recollections of the Life of the late Werner von Siemens," the well known electrician, and brother of Sir William Siemens Two editions of the German original, published in December last, were issued in the course of a few weeks

THE course of four winter lectures in connection with the London Geological Field Class will this year be delivered by Prof H G Seeley, F R S, on Tuesday evenings, at the Memorial Hall, Farringdon Street, the subject being "The Fossil Reptiles of the Thames Basin" All particulars may be had of the Hon Sec Mr J. H Hodd, 30 and 31, Hatton Garden, E C

THE bacterial purification which takes place in a river during its flow has been recently attributed in part to the process of sedimentation which the micro organisms in the water undergo, but it would seem that yet another factor must be taken into account Buchner, in some investigations which he has recently published ("Ueber den Einfluss des Lichtes auf Bakterien," *Centralblatt fur Bakteriologie*, vol 11, 1892, also vol 12, p. 217) shows that this diminution of the numbers present may be also assisted by the deleterious action which light exercises upon certain micro-organisms A systematic series of experiments was made by introducing typhoid bacilli, *B coli communis*, *B pyocyaneus*, Koch's cholera spirilla, also various putrefactive bacteria, into vessels containing sterilized and non-sterilized ordinary drinking water As a control, in each experiment one vessel thus infected was exposed to light, whilst a second was kept under precisely similar conditions, with the exception of its being covered up with black paper, by means of which every particle of light was excluded. The uniform result obtained in all these experiments was that light exercised a most powerful bactericidal action upon the bacteria in the water under observation. For example, in one water in which at the commencement of the experiment 100,000 germs of *B. coli communis* were present in a c c, after one hour's exposure to direct sunlight *none* were discoverable, whilst in the darkened control flask during the same period a slight increase in the numbers present had taken place Even the addition of culture fluid to the flasks exposed to sunlight could not impair in the least the bactericidal properties of the sun's rays In the flasks exposed to diffused daylight the action was less violent but still a marked diminution was observed In his later experiments Buchner has employed agar-agar, mixing a large quantity of particular organisms, pathogenic and others, with this material in shallow covered dishes and then exposing them to the action of light and noting its effect upon the development of the colonies For this purpose strips of black paper cut in any shape (in the particular dish photographed by Buchner letters were used) were attached outside to the bottom of the dish, which was then turned upwards and exposed to direct sunlight for one to one and a half hours and to diffused daylight for five hours After this the dish was incubated in a dark cupboard At the end of twenty four hours the form of the letters fastened to the bottom of the dish was sharply defined, the development of the colonies having *taken place in no part of the dish, except in those portions covered by the black letters* Some interesting experiments on the same subject have also recently been made by Kotljar (*Centralblatt fur Bakteriologie*, December 20, 1892) In the course of these investigations the author found that of the coloured rays of the spectrum the red favoured the growth of those bacteria experimented with, whilst the violet rays acted prejudicially, although less so than the white rays The exceedingly interesting observation was made that the violet rays actually favoured the sporulation of the *Bac pseudo anthracis*

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus* ♂) from India, presented by Mr A. Sandbach, a Triton Cockatoo (*Cacatua triton*) from New Guinea, presented by Mr Arthur Harter, a Gannet (*Sula bassana*) British, presented by Mr. F W. Ward, two Tuatera Lizards (*Sphenodon punctatus*) from New Zealand, presented by Mr W H Purvis, two Wanderoo Monkeys (*Macacus silenus*) from the Malabar Coast, a Straw-necked Ibis (*Carphibis spinicollis*) from Australia, four Snow Buntings (*Plectrophanes nivalis*), six Wild Ducks (*Anas boschas*, 3 ♂ 3 ♀) British, purchased, a Meadow Bunting (*Emberiza cia*) European, received in exchange, two Shaw's Gerbilles (*Gerbillus shawi*) born in the Gardens.

OUR ASTRONOMICAL COLUMN

COMET HOLMES.—*Edinburgh Circular*, No 37, announces that Palisa, telegraphing from Vienna, states that Comet Holmes now resembles an 8 m star with a nebulous envelope 20" of arc in diameter

A further observation made by Prof. Schur in Gottingen on January 19 showed that the nucleus was of the 10th magnitude, and could not be considered at all brighter than that magnitude. For the latter observation the air, as regards clearness, was all that could have been desired.

At South Kensington, on January 18, the comet was observed as a hazy star and estimated to be about the 8th magnitude

The following ephemeris is that given by Schulhof —

Date		R A app.			Decl. app		
		h.	m.	s.	°	′	″
Jan	26 ...	1	35	33 0	+33	42	3
	27 .		36	58 7		42	51
	28		38	25·1		43	44
	29 ..		39	52·1		44	43
	30 .		41	19 8		45	46
	31		42	48 1		46	55
Feb	1		44	17 0		48	8
	2	1	45	46 5	33	49	26

On January 30 the comet will lie very nearly between β Andromedæ and β Trianguli, about one-third of the distance from the latter star.

COMET BROOKS (NOVEMBER 19, 1892).—The following ephemeris of Comet Brooks is due to Ristenpart, and is given in *Astronomische Nachrichten*, No. 3142:—

1893	R.A. (app.) h. m. s.	Decl. (app.) ° '	Log *r*.	Log Δ.	Br.
Jan. 26	23 35 8	+40 34.3	0.0921	0.0471	2.94
27	38 53	39 34.1			
28	42 22	38 36.8	0.0950	0.0688	2.62
29	45 37	37 42.2

Feb. 1	54 14	35 13.1	0.1015	0.1101	2.11
2	23 56 48	34 27.7			

This comet, which will be found to be in the constellation of Andromeda, will lie about $3\frac{1}{2}°$ to the south of ι Andromedæ on January 27.

PHOTOGRAPHIC ABSORPTION OF OUR ATMOSPHERE.—The question of the degree with which our atmosphere absorbs photographic rays has become very important owing to the adoption of photography, so that any work enlightening us on this subject is anxiously listened to. Prof. Schaeberle, who has been making investigations in this direction, has just completed a memoir which is being published by the University of California, but in the meanwhile he has issued a table setting forth simply the final results. The absorption in the following table is expressed in photographic magnitudes, and must be added to the unknown atmospheric absorption at the zenith.

Z.D. °	Phot. Absorp.	Z.D. °	Phot. Absorp.

HARVARD COLLEGE OBSERVATORY.—The forty-seventh annual report of this Observatory, by Prof. Pickering, opens with a reference to the death of Mr. George B. Clark, to whose "genius for mechanical devices, indomitable perseverance, and devotion to the interests of the observatory, we are indebted for the success of many of our most useful instruments." Of the most important matters mentioned in the report are the permanent establishment of an observing station in South America, where the unsteadiness of the air is for the most part eliminated, the construction of a suitable building for the housing of photographs and the approaching completion of the Bruce photographic telescope. The work done with the various instruments during this period has been considerable. With regard to the Draper telescope, as many as 2777 photographs have been taken, while those taken with the Bache instrument number nearly 2000. The Boyden department, which is situated at Arequipa, in Peru, has been making great progress, the results of which have been frequently inserted in *Astronomy and Astro-physics*. The eight surfaces of the objective of the Bruce telescope have, as Prof. Pickering informs us, been ground and polished, and the results up to the present, according to tests made on a star, are very satisfactory. This instrument, when finished, is destined for the Arequipa station.

SOLAR OBSERVATIONS AT ROME.—Prof. Tacchini has issued the results of the observations made with regard to the distribution in latitude of the solar phenomena at the Royal Observatory during the third semester in 1892. From the tabulated statement which he gives the following facts may be gathered.

With regard to the eruptions, these phenomena seem to be quite local to the equatorial regions, the relative frequency being 0.667 and 0.333 for the north and south latitudes respectively. The spots, faculæ, and eruptions have their maxima nearly at the same distance from the equator both north and south, the zones being (± 20°, ± 30°), but the maxima for the prominences extend further north, about latitudes 60° north and south. Prof. Tacchini remarks that in the equatorial zone (+20° – 20°), where the maxima of faculæ, spots, and eruptions are observed, a feeble relative frequency in the prominences is noted, which shows us that we must consider a large number of prominences as the result of conditions "bien différentes par rapport à celles qui déterminent la production des taches dans la photosphère," whilst the prominences are formed simply in the solar atmosphere. As a case in point, he mentions an observation made on August 1 of last year, of a cloud which, starting at a distance of 264", rose to 364" without any corresponding alteration at the surface.

THE TOTAL SOLAR ECLIPSE, APRIL 15-16, 1893.—Writing to M. Flammarion about the scientific expedition sent by the Brazilian Government to study the region of the central plateau and to select a site for the proposed new capital, Dr. Cruls, the Director of the Observatory at Rio de Janeiro, adds the following note:—"About the total eclipse of April 16. Will France send any one to observe it? I beg you to make known through the *Review* (*L'Astronomie*) that the Brazilian Government is willing to send a warship to Ceara, on which foreign astronomers who wished to observe the phenomenon could find a passage."

GEOGRAPHICAL NOTES.

A CHANGE has been made in the arrangements for the expedition to Lake Rudolf referred to on p. 235, vol. xlvii. The expedition is to travel by the Tana river instead of the Juba, although its ultimate destination is the same, and Lieutenant Villiers, instead of accompanying it, has joined Sir Gerald Portal's mission to Uganda.

MR. H. J. MACKINDER, M.A., Reader in Geography at Oxford, delivered the first of a course of ten educational lectures, under the auspices of the Royal Geographical Society, on the relation of geography to history, on the 20th inst. The attendance was largely composed of teachers and University Extension students, to whom special terms were offered. The lecturer treated of "the Theatre of History," tracing the development of accurate geographical knowledge from the earliest times in a series of brilliant generalisations. He dwelt upon the contrast between the knowledge of early Greek geographers regarding the true shape of the earth, and their habitual representation of the regions known to them in a circular form. In the middle ages, amongst the half-learned, the map of the known world was elevated to the highest place, the figure of the globe was forgotten, and the doctrine of a flat earth gained currency. At the geographical *renaissance* the map was adapted once more to the sphere, and the discoveries of Columbus and his contemporaries resulted directly.

THE suggestion of Mr. Joseph Thomson to bestow the name of Livingstonia (vol. xlvii. p. 160) on the British sphere of influence north of the Zambesi, in spite of its singular propriety, has, we fear, failed to convince the authorities in charge of the region, who, it appears, have decided to adopt the cumbrous and scarcely accurate title of British Central Africa.

M. MIZON'S second expedition to Adamawa has been stopped on the Benué by the breakdown of his steamers, and the sudden falling of the water, he being left without means of progress about two-thirds of the way between Lukoja and Yola.

THE French flag has been formally hoisted on the little islands of St. Paul and New Amsterdam in the South Indian Ocean, midway between the Cape of Good Hope and Australia. St. Paul is an interesting instance of a volcanic island, the extinct crater of which forms a wide sheltered harbour communicating with the sea by means of a single narrow channel. It was one of the French stations for observing the transit of Venus in 1874. French fishermen from Reunion had practically taken possession of the islands in the early part of the century, but the fishing-grounds have long been abandoned.

MR. B. V. DARBISHIRE, M.A. (Oxon.), has been appointed Cartographer to the Royal Geographical Society. He has had the advantage of preliminary training in Germany, and under the Reader in Geography at Oxford.

THE APPROACHING ECLIPSE OF THE SUN, APRIL 16, 1893.[1]

I HAD the honour, two and a half years ago, of describing to you the total eclipse of the sun of December 22, 1889, which I had been to observe in the Salut Isles, French Guiana. In spite of very unfavourable atmospheric conditions I was then

[1] Address to the Astronomical Society of France, on November 2, 1892, by M. De la Baume Pluvinel. translated by A. Taylor.

able to take some photographs of the phenomena and to measure the actinic intensity of the corona Two years previously I had been to Russia to observe the eclipse of August 18, 1887, but the bad weather prevented any observations If these expeditions did not succeed as well as I had hoped, they were at least useful in showing me all the difficulties to be met with in such undertakings, and of convincing me that if one wishes to thoroughly avail one's self of the precious moments during which the eclipse lasts, it is necessary to gain a large experience of these phenomena by omitting no opportunity of observing them, and by making a speciality of these expeditions Therefore, after the eclipse of 1889 I determined to go to observe the following eclipse, that of the 16th of next April

This time the phenomenon is visible under particularly favourable conditions On the African coast to the south of Dakar, where the expedition sent by the Bureau des Longitudes will observe, and where I also propose to instal myself, the duration of totality is four minutes thirteen seconds. Moreover, a very important consideration is that we are certain of fine weather At a time when expeditions are being organised in every country in view of this astronomical event, I think it will be useful to draw your attention to the chief questions which should be the object of astronomical study during the next eclipse

You are aware that the passing of the moon before the sun has the inestimable advantage of allowing us to see the circumsolar regions which, under ordinary circumstances, because of their faint light are lost in the general illumination of our atmosphere The regions thus revealed consist of a layer in immediate contact with the sun, the chromosphere, in which are the rosy flames which form the protuberances, and a more or less extensive luminous aureole, the corona. But since the celebrated eclipse of 1868, which marks an epoch in the history of solar physics, we are able, thanks to the great discovery of Messrs Janssen and Lockyer, to study the protuberances at any time, and consequently it is only to the corona that the attention of astronomers turns during total eclipses

An invariable part of the day's programme is the study of the structure of the corona, and the luminous intensity of its various parts We need to have recourse to photography for trustworthy evidence as to this, for photography alone can give a faithful representation of the phenomena, even the best drawings always leave much to be desired Indeed, it is impossible in the space of a few minutes to exactly represent a nebulous mass as complicated as the corona, and without any definite outlines We can judge of the difficulty presented by the drawing of the corona, by remembering that even the most skilful draughtsmen have never yet been able to give us similar drawings of the great Orion nebula, although this may be studied at leisure The brilliancy of the corona varies in intensity so much from one eclipse to another, that it is difficult to determine beforehand the length of exposure needed with given apparatus to obtain as satisfactory a representation of the phenomenon as possible Moreover, the different parts of the corona differ in brilliancy, so that when the photographic action is sufficient to give a good image of the middle part, the lower portions which form the interior corona are over-exposed, while the extreme limits of the aureole are not reproduced. To satisfy all the conditions it is necessary to take several photographs with different exposures

To advantageously discuss the results obtained it is very important that astronomers should place upon each plate a uniform scale to measure the intensity of the photographic action upon it. This intensity is equal to the product of three factors, the effectiveness of the object glass, the length of exposure, and the sensitiveness of the plate If we indicate the useful diameter of the object glass by a and the focus by f, the effectiveness, defined by the international congress of photography, is $100\frac{a^2}{f^2}$ If we take plates of gelatinobromide of silver of normal sensitiveness as our unit, and let t be the length of exposure in seconds, we have the following formula to express the photographic action:—$100\frac{a^2}{f^2}t$ In working with wet collodion plates it is necessary to multiply this expression by $\frac{1}{15}$, and with plates of dry collodion it must be multiplied by $\frac{1}{100}$. The first photographs of the corona, taken with wet collodion, from 1868 to 1878, were obtained with a photographic action not greater than 2. Later, thanks to rapid plates, much greater action could be obtained Thus in 1883 a photograph obtained by M Janssen had received a photographic action equal to 918. On the negative thus obtained, the corona extended to between 30′ and 40′ from the limb of the moon, but on the other hand, details of the parts near the sun were completely wanting

We might ask whether by still further increasing the photographic action we should also extend the limits of the corona? Certainly not! for if the photographic action is too intense, the faint contrast between the extreme parts of the corona and the more or less illuminated sky is no longer appreciable on the negative. We know, indeed, that if we wish to produce the maximum contrast between two half tones we must only use just enough light for the faintest of the half-tones to give a perceptible image In America, Mr Burnham has been engaged in determining the maximum length of exposure necessary to obtain the best representation of the corona, and he has made experiments on this subject by photographing the moon and white clouds on a faintly lighted sky

In 1889, at the Salut Isles, I used five instruments, giving photographic actions varying from 185 to 13, but, doubtless on account of the peculiarly intense illumination of the atmosphere due to the short duration of totality, and the great abundance of water vapour in the atmosphere, the most satisfactory negative was that corresponding to a photographic action of 30 It is very probable that an equally good result might have been obtained with much less photographic action Mr Barnard, to whom we owe the best photographs of the eclipse of January 1, 1889, worked with a photographic action equal to 0 58 This result proves that with the sensitive plates now in use it should be possible to obtain good images of the corona on a large scale by using secondary magnifiers to increase the size of the image given by the object glass In any case we can employ object glasses of two or three metres focal length, which would give images sufficiently large to show all the details of the corona without having resort to enlargement of the plates. Nevertheless, in spite of the use of a long focus, the instrument must remain luminous enough for the time of exposure to be short The displacements of the image on the plate, caused by the imperfect adjustment of the equatorial mounting, or by an irregularity in the clockwork movement, or by the movement of the sun in declination are thus rendered inappreciable.

The photographs, when obtained, should be examined from the following different points of view First of all we wish to find if the corona, which will be observed in the month of April, 1893, at a period of great solar activity, and at an epoch when the south pole of the sun is projected on the visible part of its disc, resembles, as we have every reason to think it does, the corona of 1883, which was studied under the same conditions A great resemblance between the forms of the corona in 1889 and 1878, at the periods of minimum sun-spots, has already been noted, and if it can be established that the corona, seen under similar conditions, presents the same appearance, it will be proved that the diversity of appearance hitherto noticed depends solely upon the state of agitation of the solar surface, and the position of the observer with respect to the solar equator

If the corona should present an axis of symmetry it must be ascertained whether the poles of this axis coincide with the poles of the axis of rotation of the sun, or if, as is more usually the case, the poles of the corona are inclined at some degrees from the poles of the sun, thus resembling the position of the magnetic poles of the earth with regard to its geographical poles If the corona shares in the movement of rotation of the sun, it must be the same with its axis of symmetry, and therefore if we once observe the northern pole of the corona to the east of the northern pole of the sun, we ought to find it after an uneven number of half-revolutions, of the sun to the west of the north pole of the sun To ascertain if this is so or not, it is of the greatest importance to know exactly the orientation of the images upon the photographic plates The most exact and simple method to orient the images is to place the photographic apparatus in the position which it occupied at the moment of the phenomena, and, in the night, to photograph the trails which the stars leave in passing across the field of the lens

If the photographs should show the structure of the corona clearly, we shall be able to study the form of those luminous rays which we notice at the poles of the sun, and of those curvilinear structures which seem to extend from the middle latitudes of the sun. The study of the curvature of these structures will be very useful in verifying the exactness of one of the most favoured theories of the corona, which explains the phenomena

by supposing that matter is thrown out by the sun normally at its surface, and that its projection is turned on one side by the rotation of the sun Mr Schaeberle, of the Lick Observatory, has mathematically studied this theory, and on applying it to eclipses already observed, has been able to report that the curvature of the structures has always conformed with the theory

We must also examine the photographs taken with the longest exposure, to determine whether the dark parts which sometimes separate the luminous structures, and which we can trace to the base of the corona, are entirely destitute of light The existence of these *rifts*, as the English call them, is difficult to explain, if we suppose that the coronal atmosphere entirely surrounds the sun, for in that case we should always see, projected on the plane perpendicular to the line of sight, the coronal matter all round the sun According to Prof Hastings, the presence of these rifts is a confirmation of his theory which ascribes the corona to diffraction, and not to the existence of a material mass

Is the aspect of the corona quickly modified, or are the changes which we notice from one eclipse to another effected slowly? Hitherto we have never proved the difference between the photographs of the same eclipse taken at several hours' interval, and at stations very distant from each other The English astronomers thought of testing this question in December, 1889, and the two English expeditions sent, one to the Salut Isles, and the other to the west coast of Africa, were furnished with photographic outfits as identical as possible, in order to obtain, at an interval of two and a half hours, comparable negatives of the corona Unfortunately the complete failure of the expedition on the African coast did not permit the carrying out of this programme, otherwise it is very probable they would have proved no sensible difference between the negatives at the two stations, for photographs show that the corona of December 22, 1889, was almost identical with that of January 1 of the same year We may say, then, that during the year 1889, a year of quietude on the solar surface, the appearance of the corona did not appreciably change

However, the experiment attempted by the English expeditions needs to be repeated, if not to study the internal movements of the corona, to obtain identical photographs at two different angles, which would enable us, with the aid of the stereoscope, to judge of the *relief* of the corona

Photographs of a total eclipse will not only inform us as to the structure of the corona, but will permit us to measure its actinic brightness We can estimate the relative intensity of different parts of the corona by superposing several photographs, made on the same scale, but obtained with very different photographic actions The outlines of each image would give lines of equal actinic intensity of the corona The absolute intensity may be measured by comparing the opacity of the image on the plate with the opacities produced on the same plate from a source of standard light For this purpose the plates destined for photography are previously exposed on their borders to a standard light for varying periods of time When these plates are developed, a scale of tones which allows a comparison of opacities is obtained at the same time as the image of the phenomena

The spectroscopic examination of the corona confronts us with still more complex and more interesting problems. When we keep the slit of the spectroscope on the crescent of the sun, which narrows more and more in proportion as the moon advances, the spectrum darkens and the dark lines become less and less apparent, then all at once the field of sight is covered with an infinite number of bright lines, which seem to be substituted for each dark line of the Fraunhofer spectrum This phenomenon only lasts two or three seconds Such is the remarkable observation made by Prof Young in 1870 In the preceding year he had tried to prove this transformation of dark into bright lines, but failed because he had arranged the slit of his spectroscope as a radius to the sun, which gave the bright lines too little length to be perceptible With a tangential slit, however, the lines were long enough to be easily recognised

Prof. Young's observations revealed to us the existence round the sun of a layer of incandescent vapours, of relatively low temperature, which, conformably to Kirchoff's theory, produce by their absorbing power reversal of the lines of the solar spectrum It is very probable that the vapours to which the reversal is due are not all situated in the atmosphere which Prof Young has revealed to us, and which has a thickness of only 1000 kilometres If it were so, absorption must be infinitely more intense at the edge of the sun than it is at the centre Nevertheless, the borders of the sun show no trace of this abnormal absorption The observations of M Janssen in 1867 showed this, and it is also proved by photographs of the spectrum of the sun which I took at the annular eclipse of 1890 at Canœ in the island of Crete

It is probable that the reversal of lines is produced in a series of layers whose total thickness is great enough to make the difference of absorption between the centre and limb of the sun inappreciable According to Prof Lockyer the sun should be surrounded by concentric layers of vapours arranged in order of density, which, according to his own expression, envelope the sun like "the leaves of an onion" Prof Young's layer of vapours would comprehend only some of these layers This hypothesis seems confirmed by the observation made by M Trépied in 1882 although he saw "a veritable rain of bright lines in the spectrum," he proved that the coincidence of the bright and dark lines was not complete

Prof Lockyer's theory involves also, as another consequence, the unequal length and width of these bright lines, indeed, the layer nearest to the sun should give short lines corresponding to the thickness of this layer, and as the temperature here must be very high the lines should be rather wide The following layer being seen by projection, and having a thickness equal to the two layers, should give lines twice as long, moreover, this second layer being cooler than the preceding the lines should be narrower The same reasoning applies to the succeeding layers, so that we ought to find, soon after the beginning of the total eclipse, short and wide lines, then long and narrow ones The observations of 1882 confirmed these predictions, and English astronomers wished to repeat the experiment in 1886 Unfortunately the observations of Father Perry and Mr Turner were made under conditions too unfavourable for us to draw any certain conclusion from them. To fully elucidate the question it is necessary to obtain instantaneous photographs of these bright lines The experiment was indeed attempted by English observers in 1883, but they seem to have obtained no result Prof Lockyer proposes during the approaching eclipse to photograph these lines as well as the bright lines of the corona. He intends to use not only an analytic spectroscope, but a prismatic object glass This apparatus will give the monochromatic images of the corona, that is to say, the kind of rings corresponding to each elementary radiation emitted by the coronal light

When we turn the spectroscope towards the corona itself we observe a continuous spectrum, crossed by a bright green line which does not belong to any known element This line, near the line E, corresponds to the division 1474 of Kirchoff's scale, and was at first believed to coincide exactly with a line of iron, but in 1876 Prof Young was able to separate the line 1474 with powerful dispersion, and proved that one of its two components belongs to iron while the other belongs to the coronal matter This line 1474 has been shown in every total eclipse, but its intensity has been very variable and seems always to have followed the fluctuations of solar activity Thus in 1878, a period of maximum spots, the green line was so faintly visible that it escaped all observers except two On the other hand, in 1882, when the solar activity was almost at its maximum, the green line was visible to within 40' from the limb However, we must remember that these estimations made by different observers, observing with very dissimilar instruments, are scarcely comparable, and trustworthy evidence can only be obtained from photographs of the spectrum of the corona. The new plates sensitive to the green will no doubt allow the line 1474 to be photographed in the approaching eclipse

It would be interesting to know whether the intensity of the green line varies with the brilliancy of the different parts of the corona, whether it is completely wanting in the rifts, whether it extends further than the visible corona, whether it has the same width in its whole extent, &c. These observations can only be made by associating with the spectroscope a telescope serving as a finder, in which cross wires have been arranged to indicate at each moment towards what part of the corona the slit is directed The spectrum is observed with one eye while with the other the corona is examined This is the arrangement which M Janssen has always adopted in his spectrum observations of the corona.

If the terrestrial atmosphere is loaded with water vapour, we must expect a general diffusion of the coronal light, and this is

doubtless the reason that on some occasions, as in 1870, the green line is seen beyond the corona—even upon the lunar disc

Prof Hastings, in 1883, examined simultaneously with a special arrangement the spectra of east and west portions of the corona, and proved, conformably to the theory that he propounds, that the green line varied in length during the duration of the eclipse, and that it always extended furthest on the most illuminated side of the edge of the moon. Mr. Keeler repeated the experiment in 1889, and also noted that the length of the green line depends upon the position of the sun with respect to the moon. The question would be worth studying further

The green line is not the only bright line in the spectrum of the corona, the hydrogen lines have also been discovered in it, but these never extend further than about 10′ from the sun's limb Other bright lines in the red and in the violet were observed by M Tacchini and by Thallon in 1882 It was in 1882 also that Prof Schuster obtained the first photograph of the coronal spectrum upon which some thirty bright lines may be counted

In addition to the incandescent solid or liquid matter producing the spectrum of the corona, and the incandescent gases, which give rise to bright lines, there must also be in the circumsolar regions matter reflecting the light of the photosphere, as our own atmosphere does This is proved by the polarisation of the light of the corona, and by the presence in its spectrum of the dark lines of the Fraunhofer spectrum We owe the discovery of these dark lines to M Janssen In 1871 he observed only the lines D and *b*, but, since, in 1883, he has recognised some hundred dark lines, thus showing that the complete Fraunhofer spectrum is found in the coronal spectrum These dark lines are necessarily very faint, for they are drowned in the continuous spectrum As a rule the line D is most conspicuous, although, according to Prof Hastings, if a faint solar spectrum is projected on to the continuous spectrum of a gas flame, it is not the line D, but rather the group *b*, which is by far the most apparent Prof Hastings concludes from this experiment that the continuous spectrum of the corona is richer in green than in orange radiation, since it causes the group *b* to disappear before the line D.

In conclusion I must quote a remarkable observation made by Prof Tacchini in 1883, which, should it be confirmed, would suggest a very fascinating theory of the corona Upon examining the spectrum of one of the sheaves (panaches) of the corona with a considerable dispersion and a wide slit, Prof Tacchini thought he recognised two or three bright bands characteristic of the hydrocarbons, which are always present in the spectra of comets Father Perry in 1886 proposed to verify the observation of Tacchini, but unfortunately could not re observe the bands in question Certainly he used a spectroscope with slightly illuminated cross wires, and when the period of great solar activity had already passed It would be well in future eclipses to devote some seconds to the search for these bands, for, if the presence of carbon were recognised in the coronal atmosphere, it would be a new proof of the analogy which exists between the corona and cometary masses Like comets the corona seems formed of matter subject to a repulsive force on the part of the sun, indeed it is probable that solar gravity does not act upon the corona, for unless this were so, the lower parts, having to support the weight of the upper, would be much more dense than the latter It would thus result that the lines of the coronal spectrum, the line 1474 for instance, would be wider at their bases than at their upper extremities, but nothing of the kind has hitherto been observed Moreover, so that the corona may be visible at 30′ or 40′ from the sun, the coronal matter must necessarily not be too rare in these extreme regions; but even in ascribing an extremely low density to this, we should find upon allowing for solar gravity that the pressure near the sun would have a considerable value, although it is proved that the pressure at the base of the corona does not exceed some millimetres of mercury.

It is also sought to prove the slight density of the middle corona by the fact that it has never offered any resistance to comets, which, on several occasions, have passed through it, but as comets themselves experience no appreciable resistance when they encounter a body it is impossible to tell whether the absence of resistance is due to the comets or to the corona.

The repulsive force which expels the coronal matter from the sun would act in the same manner as electrical force; indeed Prof. Bigelow has noticed that the arrangement of plumes and sheaves round the solar disc, and the curvilinear forms exactly recall the lines of force of an electric field Let us complete the parallel between comets and the corona by noting that the tails of comets sometimes assume the curvilinear form found in the sheaves of the corona The dark parts which divide the tails of comets have also their analogues in the rifts of the corona. To push the comparison still further, it would be very interesting to be able to prove that the corona, like cometary masses, is transparent, and that bright stars can be seen through it Unfortunately it will be impossible to attempt this experiment at the time of the next eclipse

An exact photometric study of the solar surface would perhaps detect the transparency of the corona, indeed if we suppose that the corona presents a certain opacity the parts of the photosphere on which the large sheaves are projected must be less luminous than the parts covered by the polar rays

If the corona is not subject to solar gravity it is scarcely probable that it shares the movement of rotation of the sun, however, it would be useful to try in the coming eclipse to study the question by the spectroscopic method, as M Trouvelot wished to do in 1883 It would be desirable to conduct all spectroscopic observations of the corona by means of photography The instruments which must be used for this purpose should be very luminous (*i e* give bright images), for there is little light available, and the exposures are necessarily short In studying the effectiveness of a spectroscope in the case of an object presenting a large apparent diameter, like the corona, it is seen that the intensity of the spectrum depends entirely upon the width of the slit, and the effectiveness of the object glass which forms the image of the spectrum As to the collimator and the condenser their dimensions are of no importance, provided that the collimator can well receive all the light of the condenser As the object glass which forms the image of the spectrum must have an image long enough to give sufficient length to the spectrum, one is led, in order to obtain great effectiveness, to give this object glass a large aperture, and consequently to use a prism of large size

The visibility of the bright lines depending not only on their brightness, but also on their width, a wide slit must be employed to obtain a good image of these lines, on the other hand, a narrow slit will give a spectrum of great purity, and will show the dark lines The employment of two different spectroscopes is then plainly indicated

It remains for us to speak of the photometric measuring of the corona by optical photometers Bunsen's photometer has already been used for this purpose, but I think that we must henceforth turn to photography to obtain exact results The question should not be neglected, for it is certain that the brilliancy of the corona varies considerably from one eclipse to another Thus Prof Lockyer estimates that in 1878, at a period of quiescence on the surface of the sun, the corona was ten times less brilliant that in 1871

Let us end by pointing to the polariscope observations which hitherto have been far from giving concordant results as to the proportion of polarised light in the various parts of the corona Here also there are new inquiries to be made

Such, gentlemen, are the different problems suggested by the study of the solar corona We will hope that the next eclipse will largely contribute to their solution

MEMORIAL OF SIR RICHARD OWEN

A MEETING was held at the rooms of the Royal Society, on Saturday, to make preparations for the provision of a suitable memorial of the late Sir Richard Owen The Prince of Wales took the chair, and was supported by the Duke of Teck, the President, the Treasurer, and the Secretary of the Royal Society, Lord Kelvin, Sir John Evans, and Professor Michael Foster, the President of the British Association, Sir A Geikie; the President of the Royal College of Physicians, Sir A Clark; the President of the Royal College of Surgeons, Mr T. Bryant, the President of the Royal Academy Sir F Leighton; the Bishop of Rochester, the Dean of Westminster, Lord Playfair, Prof. Huxley, Sir H. Roscoe, M P, Sir F Abel, Sir F Bramwell, Sir G Stokes, Sir H Acland, Sir Joseph Lister, Mr Ericsen, Dr Priestley, Dr Gunther, Dr H. Woodward, Dr Maunde Thompson, Sir W H Flower, Sir Erasmus Ommanney, Sir James Paget, Sir Henry Thompson, Sir Spencer Wells, Sir Edwin Saunders, Sir John Fowler,

Dr E A Bond, Dr. P L. Sclater, Mr Carruthers, and Mr W. P. Sladen There were also present, among others, Sir G M Humphry, Mr Holman Hunt, Mr Ernest Hart, Dr Michael (President of the Royal Microscopical Society), Prof. R Meldola, Mr. O Salvin, and Prof T Wiltshire

The Prince of Wales, in opening the proceedings, said,—I have the great privilege conferred upon me of being asked to take the chair to-day, upon this very special occasion. We are assembled together for the purpose of paying a mark and tribute of respect and appreciation to the memory of a great man of science who has lately passed away from us The name of Sir Richard Owen must always go down to posterity as that of a great man—one who was eminent in the sciences of anatomy, zoology, and palæontology Perhaps I may be allowed to say a word of my own personal knowledge of him It is now thirty-five years since I had the advantage of knowing him When I lived as a boy at the White Lodge, Richmond Park, now occupied by my illustrious relative on my right (the Duke of Teck), I had opportunities of visiting him and knowing him His geniality and his charm of manner to all those who knew him have, I am sure, left a deep and lasting impression Whether he was explaining to you the mysteries of some old fossil bone that had been given him, or whether he was telling one of his vivid ghost stories, one felt that one was under the charm of his presence His method of teaching, as you all know, was earnest and clear in every respect, and it even derived a measure of force from a certain hesitation in his manner His great repute was gained as a zoologist, and in the study, not only of living animals, but of those long extinct, and following the same large range of work as Cuvier, to whom, in the history of science, he may be regarded as a successor One of the great works and interests of his life was the formation of the Natural History Museum, which is now safely established in South Kensington under the able guidance of our friend Sir William Flower It may be within your recollection what great difficulties Sir Richard Owen encountered when he was first appointed Superintendent of the Department of Natural History at the British Museum in 1856 He himself saw in getting that appointment that it was quite impossible that these large collections could be adequately seen unless they were removed to some other sphere In 1862 a Bill was brought in by Mr Gladstone, who took the greatest interest in the matter, while it was vigorously opposed, strange to say, by no less great a man than Mr Disraeli The Bill was lost, though it was eventually, ten years later, carried, and now we have that fine building that we all know and deeply appreciate I may also mention that he took the greatest interest with regard to the colonies, and in trying to obtain from them specimens that would be worthily represented in the Natural History Museum In sanitary matters also he was not behindhand, as was shown by his long intimacy with that distinguished man, Sir Edwin Chadwick. There are several resolutions to be proposed, and you will hear far better and more eloquent remarks from the distinguished gentlemen who will move and second them That is the reason why on this occasion I shall not trouble you with more remarks Allow me only to repeat the assurance of the deep interest I take in this movement for a suitable memorial to the memory of this great man, and how deeply I appreciate having been asked to take the chair on this interesting and important occasion

Lord Kelvin moved —"That it is desirable that the eminent services of the late Sir Richard Owen in the advancement of the knowledge of the sciences of anatomy, zoology, and palæontology should be commemorated by some suitable memorial" He said that, if there was no other reason but the part that Sir R. Owen took in the establishment of the Natural History Museum, and the success that ultimately attended his efforts, he deserved the gratitude of the nation. There was scarcely any branch of the whole of natural history that he had not touched and enriched with the results of his investigations. Three hundred and sixty papers, every one of them valuable, were to be found under his name in the Royal Society catalogue of scientific papers. From these contributions, however, he came back to the Natural History Museum, and he held that every subject of the Queen, in these islands or in the colonies, and every visitor to this country, must feel that he was benefited by the existence of that museum and by the splendid arrangement of its contents.

Prof. Huxley, in seconding the resolution, said that, if he mistook not, there were very few men living who had had occasion to follow the work of the remarkable man whose career they had met to celebrate with more carefulness and attention than he had done It was a career remarkable for its length, for the rapid rise to eminence, and the long retention of high position of the person who was the subject of it It was more than forty years ago since he, as a young man, had occasion to look abroad upon the scientific world of London, in which he was then a complete novice, and to see whether, perhaps, in some small and insignificant corner of it room might be found for him At that time there were four persons whose names stood out amongst the first in the galaxy of scientific men of this country They were Sir John Herschel, Mr Faraday, Sir Charles Lyell, and, last, though by no means least, the famous Hunterian Professor, Owen If he looked abroad amongst the lights of biological science, with which he was principally concerned, there were Johannes Muller in Berlin, Milne Edwards in Paris, Von Baer in St Petersburg, but for quantity, general excellence, and variety of work there was no one who could be regarded as the superior of Owen It was a common impression that Owen was the successor and continuator of Cuvier, and that was largely true The memoirs on the pearly nautilus, on the marsupials, on the anthropoid apes were fully worthy of the author of the "Memoires sur les Mollusques" or the "Leçons d'Anatomie Comparée," while the "Ossemen fossies" had a full equivalent in the vast series of papers upon fossil remains, contained in the publications of the Royal, the Geological, and the Palæontographical Societies But it was also to be remembered that, in another field, Owen was the successor and continuator of the school to which Cuvier was most vehemently opposed—that of St Hilaire and Oken The remarkable contributions to morphology embodied in the works on the archetype of the vertebrate skeleton and on the nature of limbs were able developments of speculative views of another order than Cuvier's Readers of Goethe would remember that he thought the news of the controversy between Cuvier and St. Hilaire far more interesting than that of the Revolution of July, which broke out about the same time Whether that was a just estimate of the relative importance of things or not might be left an open question, but it was the peculiar irony of history to show us in so many quarrels that right and wrong were on both sides And in this particular controversy it had turned out that the right lay neither with Cuvier nor with St. Hilaire, but partly with both and partly with a third party, which at that time hardly existed Whatever might be the ultimate verdict of science in this particular matter, there could be no doubt that it was a distinct aid to progress to have one view of the case stated and illustrated with the unrivalled wealth of knowledge which Owen brought to bear upon it If history confirmed, as he believed it would, the estimate of the broad features of Sir Richard Owen's work, which he had suggested, then it would justify them in endeavouring to preserve the memory of the great results achieved by his stupendous powers of work, his remarkable sagacity in interpretation, and his untiring striving towards the ideal which he entertained

The resolution was then put and agreed to unanimously, as were also those which followed

The Duke of Teck moved —"That the memorial shall consist primarily of a marble statue which shall be offered to the Trustees of the British Museum to be placed in the hall of the Natural History Museum." His Royal Highness said,—There is no doubt, in my mind at least, that this would be the most appropriate place and the most appropriate form in which to erect the likeness of our admired friend It is, so to say, his second home, the home of his later labours, and no better place could be found Besides, I think it is a very nice idea that every one who enters the hall should see first of all the man to whom we owe this inheritance Others have said so much about Sir Richard Owen that it is needless for me to go over the ground again As all of us know so well, what he has been and what he has done will remain in the minds of all who survive him, and, therefore, I will only say that in my opinion the hall, which is a very fine interior, of the Natural History Museum should be the place where the memorial of this great man should be erected

Sir William Flower, in seconding the resolution, said that having twice in his life succeeded Sir Richard Owen, he had had special opportunities of judging of his work, and he might, therefore, be expected to say something about the general character and extent of that work on the present occasion, but after what had been said in the introductory remarks of His Royal Highness, and the speech of Prof. Huxley, than whom no one

was more competent to give an opinion upon the scientific side of the question, there was no necessity for doing so. He could not refrain, however, from speaking upon one point. Among the various characteristics of Sir Richard Owen, one of the most remarkable was his untiring industry, which enabled him to produce an amount of work which was truly prodigious. It could hardly be expected that such a vast series of memoirs on so many diverse subjects, as that which he had given forth to the world during his long life, could all be equal in quality, or that the merits of some of them should not have been the occasion of controversy. He would only refer to one instance of this kind. As long ago as 1837, Sir R. Owen read a paper before the Society in whose rooms they were now assembled, which was published in the Philosophical Transactions, and in which certain remarkable characteristics were stated to exist in the brain of marsupial animals, widely distinguishing them from other members of the class to which they belong. The conclusions apparently established by this paper were generally accepted for nearly thirty years, but in 1865 another memoir was read before the same society, and also published in the Philosophical Transactions, in which a different view was taken both of the nature of the structural peculiarities and of their significance in classification. The views of the author of this second paper have generally found favour until within a few months since, when an independent investigation of the subject, carried on with all the improved methods of modern research, by Dr. J. Symington, has resulted in a declaration in favour of the accuracy of Owen's original description and conclusions. These observations may still require confirmation by others, but as he (Sir W. Flower) was the author of the second paper, he considered it only fitting that he should, at a meeting assembled to do honour to the memory of the great anatomist, from whom, on this point, he had differed so long, call attention to them. He thought this the best contribution he could make to the object for which they had gathered together.

Dr. P. L. Sclater suggested that, in addition, a memorial catalogue of the late professor's writings should be issued, with a portrait and biographical memoir.

Sir James Paget moved that a committee be formed to carry out the preceding resolutions. It would be impossible, he said, to have any better evidence that the resolutions just passed were right than the number and position of those who had offered to serve on the committee, for there was never a more representative list. Headed by the Prince of Wales, the Duke of Teck, the Archbishop of Canterbury, and the Lord Chancellor, it contained nearly 150 of the most prominent workers in all branches of science and many who were the best judges of the influence of science on the general well-being of the nation. He was the oldest person present who had worked with Sir R. Owen, and could remember him on entering St. Bartholomew's Hospital as a student in 1834. He could testify to the influence Owen had exercised in promoting the study of science by showing to all around him how keen his delight was in it, and how in itself alone it might be a sufficient reward. He resisted all temptations to leave science, though he might have been a very successful medical practitioner, and he was one of the first by whom the real reform of sanitary matters was begun in this country.

Sir J. Evans briefly seconded the motion.

Sir A. Clark moved—"That the following list of gentlemen constitute the executive committee: His Royal Highness the Prince of Wales (chairman), His Serene Highness the Duke of Teck, the President of the Royal Society, the President of the Royal College of Physicians, the President of the Royal College of Surgeons, the President of the Linnæan Society, the President of the Zoological Society (treasurer), Sir John Evans, Prof. Michael Foster, Dr. A. Günther, Prof. Huxley, Sir F. Leighton, Sir James Paget, Dr. P. L. Sclater, Mr. W. Percy Sladen (secretary), Lord Walsingham, Mr. A. Waterhouse, R.A., and Mr. Henry Woodward." Sir Andrew remarked that this memorial movement reminded them that nations no more than individuals can live by bread alone. Material prosperity did not constitute the true abiding life of a nation; it was necessary that it should live by ideas; and the nation honoured those who, like Owen, communicated new ideas which spurred others to new courses of activity.

Mr. T. Bryant, in seconding the motion, said the College of Surgeons felt the loss that science had sustained in the death of him who unquestionably was the grand expounder of John Hunter and who, more than any one else, demonstrated the value of the materials John Hunter left behind him. He did more than any one else to call the attention of the scientific world to the museum in Lincoln's Inn, and by additions to it to make it what it is. More than that, at a time when comparative anatomy and biological studies were little thought of he called attention to the value of them, the necessity for them, and the pleasures they would yield. As a young man he attended Owen's lectures, and felt the full force of his quiet enthusiasm, which was altogether independent of the materials embodied in the lectures.

Lord Playfair, in supporting the motion, said that he was the last surviving member of the Health of Towns Commission of 1844, upon which he was brought into continual intercourse with Sir R. Owen, and therefore he knew how much Sir Richard had at heart the advancement of sanitary science. This interest in it he maintained throughout his whole career. He lived close to Sir Edwin Chadwick, and although no two men could be more unlike, they were most intimate friends, and were constantly discussing how to advance the health of the nation. When Sir Richard returned from his interesting expedition to Egypt he told the speaker that he had come back in an unforgiving spirit towards Moses, because though skilled in the learning of the Egyptians, and having derived his chief commandments from those of that ancient race, he missed one important one, "Thou shalt not pollute rivers." Owen, like Prof. Huxley, exercised great influence outside the domain of science. Prof. Huxley had benefited the education of the country, and Prof. Owen had considerable influence in improving the sanitary condition of the country.

Sir W. Flower read a first list of donations, headed with one of £25 by the Prince of Wales.

Sir Henry Acland moved, and Prof. Michael Foster seconded, a vote of thanks to his Royal Highness for consenting to become chairman of the committee, and for presiding on the present occasion.

The Prince of Wales, in responding, said,—I beg to return my warmest thanks to my kind and valued old friend, Sir Henry Acland, for the way he has proposed, to Mr. Michael Foster for the way in which he seconded, and to you all for the kind manner in which you have received this resolution. It has indeed been a labour of love to me to-day to preside on this very interesting occasion, and I think that it has seldom been my good fortune to listen to more interesting or eloquent addresses than those which have fallen from the lips of those eminent gentlemen who have spoken. Nobody will take a deeper interest in the carrying out of this memorial of our lamented friend Sir Richard Owen than myself, and most sincerely do I hope that the great work that is to adorn the Natural History Museum will be worthy of a great sculptor and of the great man that it represents.

SCIENTIFIC SERIALS

Bulletin de l'Académie Royale de Belgique, Nos. 9 and 10. Classe des Sciences.—On some new *Caligides* of the coast of Africa and the Azores Archipelago, by P. J. van Beneden.—On an optical atmospheric phenomenon observed in the Alps, by F. Folie (see Notes).—On a state of matter characterised by the mutual independence of the pressure and the specific volume, by P. de Heen. It is easily shown that the density of saturated vapour at the critical temperature is variable, and depends, at constant pressure, upon the proportion of liquid enclosed in the tube. Experiments were made in order to decide whether this independence of pressure and volume was shown also at other temperatures. The liquid chosen was ether, and the volume of liquid and vapour contained in a sealed tube was read by means of a cathetometer. A series of results showed that during condensation by pressure the density of unsaturated vapour was greater than that of saturated vapour, or that the specific volume increased with the pressure. This is an experimental verification of Prof. James Thomson's pseudo-gaseous state of matter.—On the most complete reduction of invariant functions, by Jacques Deruyts.—Ex-meridian observations made at the Royal Observatory of Belgium from March to October, 1892, by L. Niesten and E. Stuyvaert.—On a new fluorine-derivative of carbon, by Frédéric Swarts. This is a liquid, of the formula CCl_3F, boiling at 24°.7, insoluble in water, and unaffected by sulphuric and nitric acids. Its density is 1.4944, an alcoholic solution of

potash destroys it gradually, forming potassium chloride, fluoride, and carbonate. It was obtained by treating carbon tetrachloride with a mixture of antimony trifluoride and bromine in equal molecular proportions. It is notable that the bromofluoride produced by the mixture acts not as a bromising but a fluorising agent.—On a simplification of some of Tesla's experiments, by H. Schoentjes. Like some recent workers in England, Prof. Schoentjes has found that most of the experiments can be produced, although with lesser intensity, without the bobbin immersed in oil, the discharge exciter, and the condenser, simply by the first Rhumkorff coil, whose dimensions need not exceed 7 × 17 cm.—On a process of sterilisation of albumin solutions at 100° C., by Émile Marchal. Albumin can be easily sterilised at 100° C., without coagulation, by first adding 0.05 gr. per litre of borax, or 0.005 of ferrous sulphate in a 2 to 5 per cent. solution, or 4 to 5 gr. nitrate of urea per litre of 10 per cent. solution. The "incoagulable albumin" thus obtained is perfectly suitable for cultivations.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, November 24, 1892.—"Memoir on the Theory of the Compositions of Numbers," by P. A. MacMahon, Major R.A., F.R.S.

In the theory of the partitions of numbers the order of occurrence of the parts is immaterial. Compositions of numbers are merely partitions in which the order of the parts is essential. In the nomenclature I have followed H. J. S. Smith and J. W. L. Glaisher. What are called "unipartite" numbers are such as may be taken to enumerate undistinguished objects. "Multipartite" numbers enumerate objects which are distinguished from one another to any given extent, and the objects are appropriately enumerated by an ordered assemblage of integers, each integer being a unipartite number which specifies the number of objects of a particular kind; and such assemblage constitutes a multipartite number. The 1st Section treats of the compositions of unipartite numbers both analytically and graphically. The subject is of great simplicity, and is only given as a suitable introduction to the more difficult theory, connected with multipartite numbers, which is developed in the succeeding sections.

The investigation arose in an interesting manner. In the theory of the partitions of integers, certain partitions came under view which may be defined as possessing the property of involving a partition of every lower integer in a unique manner. These have been termed "perfect partitions," and it was curious that their enumeration proved to be identical with that of certain expressions which were obviously "compositions" of multipartite numbers.

The generating function which enumerates the composition has the equivalent forms—

$$\frac{h_1 + h_2 + h_3 + \dots}{1 - h_1 - h_2 - h_3 - \dots},$$

$$\frac{a_1 - a_2 + a_3 - \dots}{1 - 2(a_1 - a_2 + a_3 - \dots)},$$

where h_s, a_s represent respectively the sum of the homogeneous products of order s and the sum of the products s together of quantities

$$a_1, a_2, a_3, \dots, a_n,$$

and the number of compositions of the multipartite

$$\overline{p_1 p_2 \dots p_n}$$

is the coefficient of $a_1^{p_1} a_2^{p_2} \dots a_n^{p_n}$ in the development according to ascending powers.

It is established that

$$\frac{1}{2}\,\frac{1}{\{1 - s_1(2a_1 + a_2 + \dots + a_n)\}\{1 - s_2(2a_1 + 2a_2 + \dots + a_n)\}\dots\{1 - s_n(2a_1 + 2a_2 + \dots + 2a_n)\}}$$

is also a generating function which enumerates the compositions, the coefficient of

$$s_1^{p_1} s_2^{p_2} \dots s_n^{p_n} a_1^{p_1} a_2^{p_2} \dots a_n^{p_n}$$

being the number of compositions possessed by the multipartite

$$\overline{p_1 p_2 \dots p_n}.$$

The previous generating function may, by the addition of the fraction $\frac{1}{2}$ and the substitution of $s_1 a_1$, $s_2 a_2$, &c., for a_1, a_2, &c., be thrown into the form

$$\frac{1}{2}\,\frac{1}{1 - 2(\Sigma s_1 a_1 - \Sigma s_1 s_2 a_1 a_2 + \dots (-)^{n+1} s_1 s_2 \dots s_n a_1 a_2 \dots a_n)},$$

and hence these two fractions, in regard to the terms in their expansions which are products of powers of $s_1 a_1$, $s_2 a_2$, ..., $s_n a_n$, must be identical. This fact is proved by means of the identity—

$$\frac{1}{2}\,\frac{1}{\{1 - s_1(2a_1 + a_2 + \dots + a_n)\}\{1 - s_2(2a_1 + 2a_2 + \dots + a_n)\}\dots\{1 - s_n(2a_1 + 2a_2 + \dots + 2a_n)\}}$$

$$= \frac{1}{2}\,\frac{1}{1 - 2(\Sigma s_1 a_1 - \Sigma s_1 s_2 a_1 a_2 + \dots (-)^{n+1} s_1 s_2 \dots s_n a_1 a_2 \dots a_n)}$$

multiplied by

$$1 + \Sigma \frac{2(A_{\kappa_1} + a_{\kappa_1}) \dots (A_{\kappa_t} + a_{\kappa_t}) - (A_{\kappa_1} + 2a_{\kappa_1}) \dots (A_{\kappa_t} + 2a_{\kappa_t})}{(1 - S_{\kappa_1}) \dots (1 - S_{\kappa_t})} s_{\kappa_1} s_{\kappa_2} \dots s_{\kappa_t},$$

where

$$S_\kappa = s_\kappa(2a_1 + \dots + 2a_\kappa + a_{\kappa+1} + \dots + a_n) = s_\kappa(A_\kappa + 2a_\kappa),$$

and the summation is in regard to every selection of t integers from the series

$$1, 2, 3, \dots n,$$

and t takes all values from 1 to $n - 1$.

This remarkable theorem leads to a crowd of results which are interesting in the theory of numbers.

The geometrical method of "trees" finds a place, and, lastly, there is the fundamental algebraic identity—

$$\frac{1}{k}\,\frac{1}{\{1 - s_1(ka_1 + a_2 + \dots + a_n)\}\{1 - s_2(ka_1 + ka_2 + \dots a_n)\}\dots\{1 - s_n(ka_1 + ka_2 + \dots + ka_n)\}}$$

$$= \frac{1}{k}\,\frac{1}{1 - k\Sigma s_1 a_1 + k(k-1)\Sigma s_1 s_2 a_1 a_2 - \dots + (-)^n k(k-1)^{n-1} s_1 s_2 \dots s_n a_1 a_2 \dots a_n}$$

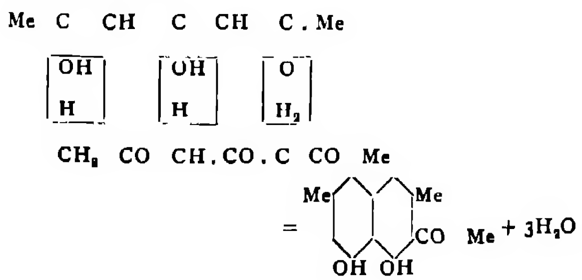
multiplied by

$$1 + \Sigma \frac{k(A_{t_1} + a_{t_1}) \dots (A_{t_n} + a_{t_n}) - (A_{t_1} + ka_{t_1}) \dots (A_{t_n} + ka_{t_n})}{(k-1)(1 - S_{t_1})(1 - S_{t_2}) \dots (1 - S_{t_n})} s_{t_1} s_{t_2} \dots s_{t_n},$$

which reduces to that formerly obtained when k is given the special value 2.

Chemical Society, December 13.—Mr. W. Crookes, Vice-President, in the chair.—The Stas Memorial Lecture, by J. W. Mallet, was read (see this vol. p. 248).

December 15.—Dr. W. J. Russell, Vice-President, in the chair.—The following papers were read:—The identity of caffeine and theine and the interactions of caffeine and auric chloride, by W. R. Dunstan and W. F. J. Shepheard. Various physiologists have concluded that differences exist between theine from tea and caffeine from coffee; the authors have compared the products from the two sources, and consider that their identity is beyond question. The differences in physiological action observed by Mays, Brunton, and Cash can only mean that the alkaloids employed were either impure or administered under non-comparable conditions. On heating an aqueous solution of caffeine aurichloride, a yellow precipitate of aurochlorocaffeine $C_8H_9(AuCl_2)N_4O_2$ separates; the production of this substance is better explained by Medicus' formula for caffeine than by that of E. Fischer.—Studies on isomeric change, ii. Orthoxylenesulphonic acids, by G. T. Moody. 1 : 2 : 3 orthoxylenesulphonic acid, when heated at 115–120° in a current of dry air, undergoes quantitative conversion into the isomeric 1 : 2 : 4 sulphonic acid. The former acid is prepared by sulphonating dibromorthoxylene and reducing the resulting dibromorthoxylenesulphonic acid with zinc dust and sodium hydroxide. A number of derivatives are described.—Studies on isomeric change, iii. Phenetoilsulphonic acids, $C_6H_4(OEt)SO_3H$, by G. T. Moody. Bromophenetoilsulphonic acid, prepared by ethylating parabromophenol and sulphonating the bromophenetoil so obtained, is readily reduced by zinc dust and sodium hydroxide with formation of orthophenetoilsulphonic acid. The latter is completely converted into the isomeric parasulphonic acid on heating for several hours at 100°. Lagai's observations, contradicting the author's previous results, are shown to be erroneous.—Formation and nitration of phenyldiazoimide, by W. A. Tilden and J. H. Millar. Phenyldiazoimide, N_3Ph, is readily obtained by the interaction of nitrosyl chloride and phenylhydrazine in glacial acetic acid solution; on nitration it yields about two-thirds of its weight of the paranitro-derivative (m.p. 74°). Nitrophenyldiazoimide is a convenient source from which to prepare diazoimide.—The production of naphthalene derivatives from dehydracetic acid, by J. N. Collie. The author concludes that the yellow substance which he has previously obtained by the condensation of diacetylacetone (see this vol. p. 238) is probably formed in accordance with the following equation:—



This substance gives a diacetyl derivative which on distillation with zinc dust yields a trimethylnaphthalene. The condensation product closely resembles the acetonaphthols prepared by Witt and Erdmann.—A new synthesis of hydrindone, by F. S. Kipping. Contrary to the statement of Hughes, hydrindone may be easily prepared in large quantities by the action of aluminium chloride on phenylpropionic chloride; 50–60 per cent. of the theoretical yield is obtained, the reaction being represented by the following equation: $Ph.CH_2.CH_2.COCl = Ph\left\langle\begin{matrix}CH_2\\CO\end{matrix}\right\rangle CH_2 + HCl$. The ketone prepared in this way is identical with that obtained from other sources by several chemists; its hydrazone, hydroxime and a nitro-derivative are described. On heating hydrindone with moderately concentrated sulphuric acid a condensation product, $C_{18}H_{14}O$, is obtained; it forms yellowish plates melting at 141.5–142.5°. Phosphoric anhydride converts hydrindone into a yellow crystalline substance, which is apparently identical with the hydrocarbon of the empirical composition C_9H_6, which the author has previously obtained by the action of phosphoric anhydride on phenylpropionic chloride.—The resolution of methoxysuccinic acid into its optically active components, by T. Purdie and W. Marshall. Synthetical methoxysuccinic acid can be resolved into its optically active constituents by crystallisation of the acid cinchonine salts, the salt of the dextro acid being less soluble in water than that of its lævo-isomeride. The separation effected in this way is, however, only partial, the metallic salts obtained after removal of the alkaloid being a mixture of the active and inactive compounds; by taking advantage of the fact that the inactive calcium or acid potassium salt is less soluble in water than its active isomeride, the optically active acids may be isolated. The active acids have a specific rotatory power of about 33° in 5–10 per cent. aqueous solutions and melt at 88–90, whilst the inactive acid melts at 108°. The rotation of the normal ammonium or potassium salt is of the same sign as that of the parent acid; the rotation of the calcium or barium salt is of opposite sign to that of the acid, but varies greatly with change of concentration. The rotation of the barium salt changes sign in very dilute solutions.—Optically active ethoxysuccinic acid, by T. Purdie and I. W. Walker. If fed with nutritive mineral salts the spores of *Penicillium glaucum* flourish in a solution of inactive hydrogen ammonium ethoxysuccinate and consume the lævogyrate acid, leaving the dextro-acid unaltered. On crystallising the cinchonidine salt of the inactive acid, a separation into the lævo- and dextro modifications may be effected, and the oppositely active acid ammonium salts prepared in this way resemble that obtained by means of *Penicillium glaucum*. Close parallelism exists between the methoxy- and ethoxy succinates, with respect to optical activity.—The formation of benzyldihydroxypyridine from benzylglutaconic acid, by S. Ruhemann. Ethyl benzylglutaconate slowly dissolves at 100° in concentrated aqueous ammonia, yielding a solution, from which acids separate benzyldihydroxypyridine. This substance exhibits both basic and acid properties and melts at 184°.—The action of nitrous acid on 1 α-amido 2-β naphthol; a correction, by R. Meldola. The author agrees with the statement of Grandmougin and Michel that β naphthaquinone results from the interaction of nitrous acid and 1-α amido-2 β naphthol.—Note on the action of phenylhydrazine on mono- and di-carboxylic acids at elevated temperatures, by W. R. Hodgkinson and A. H. Coote. On distilling a mixture of phenylhydrazine and phenylacetic acid in equivalent proportion, benzene, aniline and a liquid of the composition $C_{14}H_{12}O_2$ distil over; nitrogen and ammonia are also evolved. As has been previously shown, the hydrazide of the composition $Ph.CH_2.CO.NH.NH.Ph$ is the first product of the reaction; on distilling this substance, NH.NH is split off, and reduces the phenylhydrazine present to aniline and benzene. Somewhat similar reactions occur in the cases of orthotoluic, phenylpropionic, and succinic acids, and are now under investigation.

SYDNEY

Royal Society of New South Wales, September 7, 1892.—Prof. Warren, President, in the chair.—Paper read: The effect which settlement in Australia has produced upon the indigenous vegetation, by A. G. Hamilton [Part I.]

October 5.—Prof. Warren, President, in the chair.—The second part of paper on the effect which settlement in Australia has produced upon indigenous vegetation, by A. G. Hamilton, was read, after which the society's bronze medal and a cheque for £25 were presented to the author.

November 2.—Prof. Warren, President, in the chair.—Dr. William Huggins, F.R.S., was elected an honorary member of the Society. The following papers were read:—Preliminary note on limestone occurring near Sydney, by H. G. Smith.—On a cyclonic storm near Narrabri, by H. C. Russell, F.R.S.—Some folk-songs and myths from Samoa, translated by the Rev. G. Pratt, with introduction and notes by Dr. John Fraser.

PARIS

Academy of Sciences, January 16.—M. de Lacaze Duthiers in the chair.—Swimming movements of the ray fish, by M. Marey. These were investigated by means of chronophotography, ten exposures being made per second. The fish was fixed in position by the head and tail, and the views were taken from the front and the side respectively, the fins being left free

to move The photographs show the successive phases of one entire motion of the fins, which consists of a wave like motion beginning in front Shortly after the anterior portion has been lifted it is depressed, the motion being meanwhile propagated to the lateral portions, and growing in amplitude as the fin grows in breadth Just before the movement dies out near the tail the process recommences in front The periodic time was 0 8 seconds The photographs show a striking likeness to those obtained by chronophotography applied to the flight of birds M Marey intends to study the mechanical effect of the action of the fins upon the water, also by the aid of photography — Microscopic researches on the contractility of the blood-vessels, by M L Ranvier The periœsophagian membrane of the frog was placed on the disc of the slide cell in one or two drops of peritoneal serum It was kept extended by a platinum ring, electrodes of tinfoil were placed in connection, and a cover glass was fixed over the whole with paraffin Thus mounted, the smooth muscular fibres and the internal elastic sheath are well seen On connecting the induction coil with the electrodes, the muscular fibres contract as soon as the current is strong enough At the same time, the folds of the internal sheath become more pronounced and finally touch, thus effacing the passage through the small artery On breaking the current, the artery gradually regains its original diameter If the current is not sufficiently strong for producing a regular contraction, some of the segments contract, while others are at rest But the zone of contraction is never displaced, and, if interrupted, will reappear at the same place on reestablishing the current Nothing corresponding to a peristaltic motion can be produced by direct electrical excitement In none of the experiments, even with the strongest currents, was it possible to detect any signs of contraction in the capillaries —On the sum of the logarithms of the first numbers not exceeding x, by M Cahen —On differential equations of a higher order, the integral of which only admits of a finite number of determinations, by M Paul Painlevé —On linear differential equations with rational coefficients, by M Helge von Koch —Electric waves in wires, depression of the wave propagated in conductors, by M Birkeland (see *Wiedemann's Annalen*, abstract) —On the minimum perceptible amount of light, by M Charles Henry This was estimated by Aubert at $\frac{1}{300}$th of the light of the full moon This is about a thousand times too great, as proved by some measurements made with the zinc sulphide (phosphorescence) photometer previously described The corrected formula for the rate of loss of luminosity of the sulphide is $i^{0\cdot 5}(t - 18\cdot 5) = 1777\cdot 8$, which agrees even with the longest observations, and is theoretically justified by M Henri Becquerel The minimum perceptible amount of light was determined by noticing the time at which the eye, previously kept in the dark for one hour, could only just distinguish the light emitted by the phosphorescent substance, taking care to test for illusions by the successive interposition of ground glass screens The time thus found was four hours, giving an amount of light of 29×10^{-9} standard candles at 1 m If the eye is previously kept in the dark during varying periods, the minimum varies inversely as the square of the time during which it is kept dark —On phosphorescent sulphide of zinc, considered as a photometric standard, by the same Careful tests showed that the light emitted by zinc sulphide at a given instant is independent of the distance of the illuminating magnesium ribbon, of the time of illumination, and of the thickness of the layer, and is also uniform in samples prepared under different conditions, thus exhibiting all the requisites of a secondary photometric standard —On an acid plato nitrite of potassium, by M. M Vèzes.—Decomposition of chloroform in presence of iodine, by M A. Besson —On some ethers of homopyrocatechine, by M H Cousin.—On the determination of phosphorus in iron and steel, by M Adolphe Carnot The new method, based like most others on the employment of ammonium molybdate, differs from them in the mode of separation of the silicon, which is effected by sulphuric acid, in the process of destruction of the carbon compounds, brought about by chromic acid, and in the nature of the final compound, which is not magnesium pyrophosphate, but dry phosphomolybdate of ammonia, which only contains 1 628 per cent. of phosphorus, thus ensuring a greater accuracy in the quantitative estimation.—Losses of nitrogen in manure, by MM. A. Muntz and A Ch Girard.—Researches on the localisation of the fatty oils in the germination of seeds, by M Eugène Mesnard It appears that, except in the grasses, the fatty oil is not specially localised. It is in all cases independent of the starch and the glucose, but it appears superposed upon the albuminoid materials in the reserves of ripe seeds.

BERLIN

Physical Society, December 16, 1892 —Prof Kundt, President, in the chair —Dr Lummer spoke on the principles involved in the use of half-shade polarimeters. He showed that the difference in brightness of the two halves of the field of the instrument depends first on the angle between the two polarising prisms, the less this is the greater being the difference produced by a minimal rotation of the analyzer, and secondly on the power of perceiving minute differences of brightness In connection with the latter he had made some changes in the Lippich instrument which presented some distinct advantages —Prof Goldstein gave an account of some experiments made many years ago, but not yet published He first dealt with the light which appears at the anode, and which, as compared with that of the kathode, has as yet been but little investigated As is well known, a kathode consisting of two metals emits rays of different brightness from its two parts, thus for instance the aluminium emits brighter rays than does the silver When this electrode is used as an anode, the reverse holds good, inasmuch as the anodic light of silver is brighter than that of aluminium The difference is, however, only observed in rarefied oxygen, and does not exist in a hydrogen tube, and is hence due to oxidation of the silver The second set of experiments dealt with Crookes' supposed reciprocatory deflection of kathodic rays of similar direction The speaker had shown, by shielding one of the electrodes, that the deflection is apparent, not real The change in the path of the kathodic radiation is due entirely to the effect of the second electrode upon the rays emitted by the first

TROPICAL AGRICULTURE

A Text-book of Tropical Agriculture By H A Alford Nicholls, M D, F L S, C M Z S, with illustrations, pp 312 (London Macmillan and Co, 1892)

THIS text-book is the English edition of a work that has already received high commendation from the Government of Jamaica The Government of this now prosperous colony, in pursuance of a policy (which may well be followed by other colonies) offered a premium of one hundred pounds for the best text-book of Tropical Agriculture adapted for the use of colleges and higher schools in the colony The award was made to Dr Nicholls's manuscript, and after the publication of the work in Jamaica it was adopted also as a text-book by the Government of other colonies, so that its value has been practically estimated beforehand The author's qualifications for the task he has undertaken may be gathered from the following —

"Twelve years ago, when he had to direct his attention to tropical agriculture, there was no practical book that he could turn to for help in all the difficulties that were constantly cropping up in his path Knowing, therefore, the obstacles that usually beset the inexperienced planter who is not content to follow the old grooves of unscientific agriculture, the author has so written the second part of this book as to afford the information he needed greatly in his own planting novitiate This has rendered it necessary to enter into details, which to the experienced agriculturist may appear superfluous, but the book is really intended as a guide to the young and unlearned to whom such details are likely to be of essential service"

As an introduction to tropical agriculture this book supplies a want long felt There are several works of a technical character treating of old and well-established industries such as sugar, tea, coffee, cacao None of these, however, could be adopted as text-books in schools Indeed they all presuppose such a close acquaintance with the principles and terminology of tropical agriculture that they appeal to a very limited class of readers Hitherto, tropical agriculture, to a large extent, has borrowed most of its methods from the agriculture of temperate climates and adapt them, as well as it could, to the very different circumstances of the torrid zone The result has been by no means satisfactory In tropical regions effects follow cause so rapidly that methods admirably adapted to the cold, sluggish climates of northern countries are most injurious when too closely followed in the tropics. As instances we may cite the serious effects on climate following the extensive cutting down of forests, and the wholesale washing away of surface soil from land under permanent cultivation by the destructive influences of tropical rains. The merit of Dr Nicholls's book lies in the fact that its precepts are directly based on his own experience, and he appeals so effectively to the intelligence of his readers that they cannot fail to be instructed The work is divided into two parts:—Part I. deals with the elementary principles of agricultural science and discusses amongst other subjects the origin and composition of soils, the nature of plant life, the controlling influence of climate, the action and constituents of manures, the rotation of crops, the drainage of soils, irrigation, tillage operations, pruning, budding, and grafting. In Part II there is treated the application of these principles to some of the chief of the various cultivations undertaken in tropical countries As examples we may mention that there are detailed accounts given of the methods found most successful in the cultivation of coffee, cacao, tea, sugar-cane, fruits, spices, tobacco, drugs, dyes, tropical cereals, and such food plants as cassava, arrowroot, yams, sweet potato, tania (*Colocasia*)

The book is intended also, according to the preface, to be of service to peasant proprietors, owners of small estates, and to those [European] settlers who from time to time may wish to make their homes in the tropics It is just these people who are now building up the new prosperity of the West Indies by means of what are called "minor industries" or *la petite culture*—which the French have found so remunerative in many of their colonies To guide and instruct the mass of small cultivators in the West Indies has been the dream of the most enlightened Governors, such as Sir John Peter Grant, Sir Anthony Musgrave, Sir William Robinson, and others that have ruled there for the last thirty years The intelligent settlers of European origin can very well take care of themselves but the mass of the small cultivators are black people They have, it is true, received some education, and they are not wanting in intelligence in regard to what concerns their own interests, but their methods of cultivation have, hitherto, been of the rudest and most destructive description They crop the land year after year without any manuring, and when it is thoroughly exhausted they move on, when they can, to fresh land, and treat that in exactly the same way Thus in the black man's system of cultivation the rotation is of land, and not of crops, and the future has to take care of itself This is a relic of the times of slavery, when the negroes were allowed as much land as they cared for—out of reach of sugar cultivation—to grow provisions for their own subsistence It is now necessary to change the whole character of the black man's cultural methods, or the rich and fertile lands still left in the West Indies will be absolutely ruined. Generally only the lowest class of negroes have hitherto been attracted to field work. The education given to these people is responsible for something of this result, for it leads them, in too many cases, to regard labour in the field as degrading, and almost a return to a state of slavery. The sharper and more intelligent boys, when they leave school, are drawn away to seek a precarious existence as clerks in stores or as small shopkeepers, where they seldom do more than copy the weaknesses and vices of the whites, while, according to our author, if they took to the land, and had a right understanding of agricultural methods, they "need never despair of becoming prosperous" In the more advanced colonies, such as Jamaica, there is a disposition to establish industrial schools and train the younger generation in approved methods of cultivation, and lead them to regard the tillage of the soil as a more honourable and remunerative occupation than petty trading We may hope that the claims of industrial education will become more widely recognized, not only in the West Indies but in all our tropical colonies where native races have to be dealt

with In the meantime colleges and schools must prepare competent instructors for the work, and for both teacher and taught this book is an admirable starting-point In it the whole field of small industries is well covered, and the language is clearly expressed and well chosen. As an example of the author's treatment we find under manures (p 49) :—

"The land must be regarded by the planter as a bank in which he has opened an account If he continually draw cheques on the bank, and make no fresh deposit to meet the drain, he will sooner or later come to the end of his capital, and the same argument applies to the soil In cacao and coffee cultivation in the West Indies, particularly on lands of peasant proprietors, one often sees the planter take away crops year after year, whilst he does next to nothing to make up for the heavy drain on the land; and then, after a time he finds he gets very small crops, and he thinks the fault lies with the trees, or that the soil is not adapted to the cultivation, whereas the fault is entirely his own, as he has gone on taking away from the soil without putting anything back." Again, "the great fault hitherto committed by tropical planters has been the confining of their attention to one kind of cultivation on their land If several different crops were taken off alternately, as in a system of rotation, or grown in different parts of the land, where the soil and climate prove suitable, the planter would be in a much better position than he is now, for he would not 'have all his eggs in one basket'"

It is noticed that the valuable services rendered to colonial industries by Kew and by the various botanical institutions in correspondence with Kew are fully recognised Further, the dedication of this first Text-book of Tropical Agriculture to Sir Joseph Hooker is a compliment not only to his own distinguished services, but also to those of his father, for both in their day took the deepest interest in the West Indies It must be gratifying to the late Director of Kew to learn "in the quiet of his retirement that the influence of his work lives on and bears fruit even in the far-away field" of the West Indies

D M

CELLS THEIR STRUCTURE AND FUNCTIONS

Die Zelle und Die Gewebe, Grundzuge der allgemeinen Anatomie und Physiologie Von Prof. Dr Oscar Hertwig (Jena Gustav Fischer, 1892)

TEXT-BOOKS on Histology introduce the structure of the tissues to their readers by a chapter on cells, and the best treatises on Anatomy, either human or comparative, usually devote some pages to the consideration of these, the most elementary of all the tissues. As so many important advances have been made of late years in our knowledge of the structure of cells and their contained nuclei, of the properties of protoplasm, of the division of nuclei and the part played by the nucleus in cell multiplication, and of the influence exercised by cells in the problems of hereditary transmission, the time has obviously arrived for the production of a treatise devoted to the description of the cell in its various aspects, observational as well as speculative. No better expositor of the subject in all its bearings could be found than Prof. Oscar Hertwig, who has himself conducted important investigations on this branch of anatomy. The book now before us treats of the general anatomy and physiology of cells, and is to be followed by a second volume, in which the origin and physiological properties of the tissues are to be expounded, as well as their structure.

After a sketch of the history of the cell theory and of the theory of protoplasm, in which, as is too often the case in German text-books, the names of British observers and authors are conspicuous by their absence, he defines a cell to be a little clump of protoplasm which incloses a specially-formed constituent, the nucleus; a definition which accords with those previously made by Leydig and Max Schultze. He then describes at considerable length the characters of protoplasm, both anatomical and physiological, and the chemico-physical and morphological properties of the nucleus. In a short section he discusses the question, Do elementary organisms exist without nuclei? i.e Can you have little clumps of non-nucleated protoplasm pursuing an independent life? As is well known, Haeckel described organisms of this simple character, as cytodes, and gave Monera as an example, but Hertwig is disposed to think that such non-nucleated organisms have not been definitely demonstrated in the animal kingdom, and he quotes Butschli's observations, which seem to show that even in such micro-organisms as Bacteria a differentiation of a nucleus from surrounding protoplasm can be distinguished

Two important chapters are written on the movements of protoplasm, of cilia, of flagella, of spermatozoa, on contractile vesicles, and on the irritability of protoplasm under the stimulus of heat, light, electricity and several kinds of mechanical and chemical irritants The fifth chapter is devoted to the consideration of the nutritive changes and formative activity in cells Illustrations are given of the power possessed by certain unicellular organisms of taking into their substance and digesting solid bodies of various kinds, and an account is appended of the important observations of Metschnikoff on phagocytosis

Chapters six and seven are occupied with a description of the multiplication of cells, their mode of division, and the method of fertilization The process of karyokinesis is described at some length and in its various phases, in clear and precise language, and with an amount of illustration which enables the reader to follow without difficulty this complicated process The influence exercised by the nucleus, and the part which it plays in the process of cell multiplication, has now been put by the labours of many investigators on a basis of observation, both as regards plants and animals, such as cannot be controverted, and the accuracy of the generalization made half a century ago, both by Martin Barry and John Goodsir, that young cells originate through division of the nucleus of a parent cell, has been amply established

Dr Hertwig also recites observations which seem to show that the nucleus does more than act as a reproductive centre within the cell, but also takes a part in cell nutrition. This function of the nucleus was also contended for by Goodsir, but during the period when protoplasm was regarded as the essential element in nutrition or secretion, the claim of the nucleus to take any share in this phase of cell activity was summarily put aside. Recent observations have, however, shown that

clumps of protoplasm, removed from either a unicellular plant or animal, in which no nucleus is present, although capable of living, and retaining their irritability and power of movement for some time, yet neither grow, nor form a cell membrane, nor have the same power of digesting bodies introduced into their substance, as is possessed by a clump of protoplasm which has retained the nucleus The nutritive activity of the protoplasm would appear, therefore, to be under the influence of the nucleus

The volume concludes with a chapter on the cell in its relation to theories of heredity The author, as is now the prevailing opinion amongst biologists, contends that the nucleus is the conveyer of hereditary properties, and that the offspring is a mixed product of both its parents, derived from the ovum and the sperm cell In the course of this chapter he discusses the views of Darwin, Spencer, Nageli, Weismann, and De Vries, and suggests the employment of the term "Idioblasts" for the minute elementary particles, which Darwin called "gemmules" in his hypothesis of pangenesis, and which he conceived to be capable of transmitting hereditary characters to succeeding generations

THEORETICAL MECHANICS

Elementary Mechanics of Solids and Fluids By A L Selby, M A (Oxford Clarendon Press, 1893)

AT a period when we are bound to recognize the influence exerted by the examinations of the various educational institutions and of those controlled by other more or less influential examining bodies, we may be excused, on the arrival of a new work, for stating whether or not, and to what extent, it is adapted to their requirements. The book before us does not appear to have been intentionally written for examination purposes, and perhaps on this account it will be all the more welcome Its purpose, however, is very distinct It is intended for those students who are desirous of reading mechanics as an introduction to a study of physics So far, therefore, as its suitability for examinations is concerned, we can heartily recommend it to those who wish to qualify in this particular branch of science, while at the same time it will be read with great benefit by that class of students who desire a thorough knowledge of the portions generally included under the head of Theoretical Mechanics

In the study of such subjects as the book treats of, the amount of knowledge which the reader may have of mathematics will, to a considerable extent, be a measure of his success The author expresses a hope that an acquaintance with the elements of algebra and geometry will suffice ; but, while not wishing to reduce the usefulness of the book, but rather to direct it into proper hands in which it will be read with greater advantage, we think it would be nearer the mark to say that a thorough knowledge of elementary algebra and a considerable acquaintance with elementary trigonometry are necessary. Certainly the definitions of the trigonometrical ratios will be found in an appendix, but it will be far better if the student has lived with and used these for some time.

Possessing these requirements, he will appreciate and even admire the broad, yet concise nature of the treatment generally, and with regard to this matter we may say that we are unacquainted with any elementary text-book better calculated to create a desire for precise and full ideas That this is requisite for a study of physics perhaps more than any other subject, no one will deny

The first chapter of the book is occupied with a consideration of Kinematics, and in it will be found a careful exposition of the displacement, velocity, and acceleration to which a body may be subjected, due attention being drawn to what is necessary for a full representation of them The appendix following this contains some geometrical theorems and definitions for subsequent use Then follow the usual chapters on the laws of motion, work, and energy, centre of gravity, moments of inertia, and simple machines A chapter on gravitation will be read with interest, preceded as it is by an explanation of some of the geometrical properties of the ellipse Kepler's laws of planetary motion are dealt with; in addition to other relevant matters which do not usually find their way into elementary text-books.

The subject of elasticity also receives a somewhat more extensive treatment than is usually given to it The various kinds of stress and strain which a body may undergo are explained, together with the relation between stress and strain At the end of the book we find what is included under the second head of the title The various principles and laws which refer to fluids, and some of the machines and instruments which depend on them for their action, are enumerated and explained, while the interesting subject of capillarity has a separate chapter devoted to it

To an appreciative reader it is a source of satisfaction to observe the care the author has exercised when dealing with the important matter of definitions and units—fundamental and derived A chapter on units and their dimensions is furnished at the end.

A good selection of examples, bearing on the matter treated therein, will be found at the close of the chapters

Many portions of the book are characterized by a decided freshness of treatment, and we have little doubt that the careful reader will find many little points which are satisfying, in that they tend to widen the somewhat restricted views he may have previously held, and these will be all the more apparent should his mind be of a mathematical turn. G. A B

OUR BOOK SHELF

Magnetism and Electricity By R. W. Stewart. (London W. B. Clive and Co)

THE book forms one of the University Correspondence College Tutorial Series, and is "primarily written for the use of candidates for the Matriculation, Intermediate Science, and Preliminary Scientific Examinations of the University of London" The author is evidently familiar with the difficulties which usually occur to students, and the best portions of the book are those in which efforts are made to elucidate some of the more general errors The descriptions of apparatus and phenomena are, however, generally rather short and meagre, while the diagrams are frequently inadequate for a work of this sort Little is written to help the beginner to perform experiments for himself ; in fact, descriptions of many important instruments are omitted—for example, the Wheatstone

Bridge—and to students having no access to a laboratory little satisfaction will be given when told "The details of the construction and practical use of the different forms of Wheatstone's Bridge used in the measurement of resistance are best learnt in the laboratory, and for this reason we shall not give any further description of the arrangement"

In many instances the student is driven through a mass of theory before he has a fair idea of the general phenomena, thus in the introductory chapter on "Current Electricity," after a six-line description of a simple cell and current, over two pages are occupied in proving that the effects produced could be explained by the dissociation and procession of the hydrogen and oxygen atoms. The work is generally remarkably free from errors and misprints, but one occurs in the explanation just mentioned The attraction of zinc for oxygen is said to be much greater than that of the copper, while later the zinc is also considered "to *repel* hydrogen *less*" Here, and in many other instances, the words to be emphasised are printed in italics Another mistake will be found on pp 168 and 169, where in comparing, by the method of oscillations, the field due to a magnet with that of the earth, the author starts with the equation $\frac{I+H}{I}=\frac{n_1^2}{n^2}$ instead of $\frac{I+H}{H}=\frac{n_1^2}{n^2}$, and reasoning correctly from this false hypothesis, he deduces false results, while the answer to Ex 8 on this part of the subject appears incorrect Fig 13, p 201, in illustration of Oerstedt's experiment, is not correctly drawn.

The arrangement of "calculations" and examples at the end of each chapter must prove extremely useful to students possessing beforehand an elementary knowledge of the general phenomena, and to such, rather than to the very beginner, the book may be commended H S J

Manners and Monuments of Prehistoric Peoples By the Marquis de Nadaillac Translated by Nancy Bell (N D'Anvers) (New York and London G P. Putnam's Sons, 1892)

A BOOK summing up in a popular style all that is now known with regard to prehistoric man would probably be welcomed by a tolerably large class of readers The present work does not quite supply the kind of summary that is wanted The author does not distinguish with sufficient clearness between the various periods with which he deals, he indulges too freely in talk of a vaguely moralising tendency, and some of his statements do not accord with the conclusions of the best authorities Speaking of the Round Towers of Ireland, for instance, he says, "According to the point of view of different archæologists, they have been called temples of the sun, hermitages, phallic monuments, or signal towers" The reader is thus left to suppose that the question is still open, whereas all competent students of the subject accept the theory of the late Mr. Petrie, a theory which the Marquis de Nadaillac does not even mention However, the author has presented a large number of interesting facts in the course of his exposition, and there are occasional passages in which he brings out very well the attractive elements of some of the more fascinating departments of archæology.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications*]

Two Statements.

IN a letter addressed to the *Daily Chronicle*, dated January 15, 1893, Prof. Karl Pearson makes two statements respecting my opinions and grounds of action:

"As in society at large, so in academic matters, his mode of insuring progress is unlimited individual competition,"

and again

"he is an individualist in all matters"

Seeing that in an essay "On Administrative Nihilism," published twenty-two years ago, and in another on "Government Anarchy or Regimentation," published in 1890, I have done my best to combat the doctrine Prof Pearson attributes to me, I shall be glad to know what justification he has to offer for so grave a misrepresentation. The purpose of it is obvious

T H HUXLEY

Hodeslea, Eastbourne, January 29

A Meteor

THE following is taken from the Pretoria *Weekly Press* for January 7 "A few evenings ago a meteor of unusual size and brilliancy was observed at Bloemfontein shooting right across the eastern sky It looked like a rocket of a greenish colour, and burst in a shower of sparks in the south-east The spectacle was much admired by those who were fortunate enough to witness it"

This meteor, as seen in South Africa, appears to have had many points in common with a similar one seen in England about the same time, and reported by several observers in the daily Press

"Hare-lip" in Earthworms

ATTENTION has recently been drawn by Prof Andrews (*American Naturalist*, September, 1892) and myself (*Science Gossip*, 1892) to some abnormal conditions of life among the terrestrial annelids. I have now to place on record a totally new appearance, which is, I think, very aptly expressed by the term "hare-lip." The worm which I have had under examination presented the peculiarity figured below, and when alive and in motion suggested to my mind most forcibly the appearance which we associate with the name I have adopted.

The specimen in question belongs to the genus Allolobophora, in which genus, so far as my experience goes, almost all the abnormalities are found The genus Lumbricus, it should be observed, is very seldom, if ever, known to present any of these peculiarities Hitherto the Long worm (*A longa*, Ude)

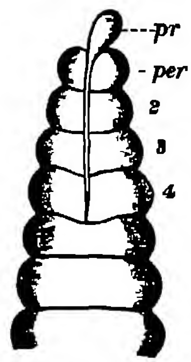

Diagram of the anterior portion of green worm (*Allolobophora chlorotica* Savigny), showing abnormal appearance of lip (*pr*), peristomium (*per*), and three succeeding segments, seen from above, and enlarged.

has been most prolific of bifurcated heads and tails. Now we find the Green worm (*A chlorotica*, Savigny) yielding new features for study. The peculiarities which have presented themselves in former times have usually taken the form of a second head or a supernumerary tail. In this instance there is no off-growth, however, but merely a malformation of the anterior segments. One might have supposed that the peculiarity was due to accidental causes. It would have been easy to suppose that the head had been split, and then the wound had healed, leaving a seam down the middle I observed, however, that each of the three specimens of the Green worm which I received from Cork (Ireland) showed some abnormal feature, and there were other peculiarities in this particular specimen which indicated that we had to deal with a congenital rather than an accidental condition of things.

As this is the first occasion on which such a peculiarity has been recorded or figured, I prefer to leave all speculation as to the cause out of the question. We need a good deal more research before we can deal satisfactorily with the biological problems involved in such appearances. As a help towards this, I bring together here a list of all those works which have come under my own and Prof. Andrews's notice, in which abnormalities in annelids are recorded:—

1. Andrews. "Proc. U.S. Nat. Mus.," vol. xiv., p. 283, 1891.
2. Andrews. "Amer. Nat.," vol. xxvi., p. 725, 1892.
3. Bell. "Ann. Mag. Nat. Hist.," vol. xvi., p. 475, 1885.

HILDERIC FRIEND.

The Zero Point of Dr. Joule's Thermometer

IN the course of a discussion on "Exact Thermometry" I described (NATURE, vol. xli. p. 488) the results obtained by heating thermometers for a considerable time to 280° and 356°, and pointed out by means of a diagram that at 356°, after about ten hours, the rise of the zero point became—at any rate approximately—a rectilinear function of the logarithm of the time, though at 280°, even after more than 300 hours' heating, the rise appeared to be rather more rapid than would correspond to such a simple relation.

Dr. Joule observed the rise of the zero point of a thermometer at the ordinary temperature during a course of no less than thirty-eight years ("Scientific Papers," vol. i. p. 558), and it occurred to me that it would be of interest to ascertain the relation to the logarithm of the time in this case also.

The following table contains the dates of Dr. Joule's observations, the total number of months from the date when the first reading was taken; the corresponding logarithms, the total rise of the zero point in scale divisions (13 divisions to 1° F.), the total rise calculated from the formula $R = 6{\cdot}5 \log t - 4{\cdot}12$, where t is the time in months; and lastly the differences between the observed and calculated zero points.

Date.	Time in Months.	Log t	Total rise of zero point in scale divisions. Observed.	Calculated.	Δ

The agreement between the observed and calculated values is certainly remarkable, and the + and − differences are evenly distributed.

Ten years have now elapsed since the last reading was taken, and if the thermometer is still in existence it would be of great interest to know what further rise has taken place in its zero point. According to the equation the reading should now be 13·86.

SYDNEY YOUNG.

University College, Bristol, January 20.

THE APPROACHING SOLAR ECLIPSE, APRIL 15-16, 1893.

THE total solar eclipse of April 15-16, 1893, is not only one of the longest of the century, but is the last of the century from which we are likely to get any addition to our knowledge of Solar Physics. The longest duration of totality of this eclipse is 4 minutes 46 seconds, and as the path of the moon's shadow lies to a great extent on land, there is a considerable choice of possible stations with long durations of totality. Commencing in the Southern Pacific the line of totality passes in a north-easterly direction and enters Chili at Charañah in 29° southern latitude, crosses the South American continent, and issues at Para Cura, a village near Ceara, at the north-east corner of Brazil, in latitude 3° 40′ south. It crosses the Atlantic at its narrowest part and enters Africa at Point Palmerin, near Joal, almost midway between Bathurst and Dakar, and in latitude 14° north, the shadow finally leaving the earth in the interior of Northern Africa. The eclipse will be observed by several parties of astronomers in Chili, Brazil, and Africa, there being almost absolute certainty of fine weather in Chili and Africa, and a reasonable probability in Brazil.

The English arrangements to observe the eclipse have been made by a joint committee of the Royal Society, the Royal Astronomical Society, and the Solar Physics Committee of the Science and Art Department, South Kensington, Dr. A. A. Common, LL.D., F.R.S., undertaking the duties of Secretary. Two expeditions will be sent from England, one to Africa and the other to Brazil, the expenses being defrayed by a grant of £600 from the Royal Society.

The African expedition will be in charge of Prof. T. E. Thorpe, and will consist of Prof. Thorpe, Mr. A. Fowler, Mr. Gray, and Sergeant J. Kearney, R.E. The Brazilian expedition will be in charge of Mr. A. Taylor, who will have with him Mr. W. Shackleton.

Prof. Thorpe and his party will leave Liverpool by the British and African mail steamer on March 18th, arriving at Bathurst on April 2nd. They will be met at Bathurst by a gunboat kindly placed at the disposal of the expedition by the Admiralty, and will be conveyed at once to Fundium, a station on the Salum River, about sixty miles from Bathurst; this being the station selected by the Committee from the three which were offered by the French Government. The gunboat will remain with the expedition, and the officers and crew will assist in the preparations for and in the actual observations of the eclipse. After the eclipse the party will be taken to Bathurst on the gunboat, and will return to England by a British and African mail steamer, if one is available. From the time-tables of the steamers now published it appears, however, that there will not be any mail steamer available until the end of April, and in this case a cruiser will meet the party at Bathurst and bring them to the Canary Islands or to Gibraltar, from either of which places they will be able to return by mail steamer, arriving in England early in May.

The members of the expedition to Brazil will leave Southampton by the Royal Mail steamer on February 23 for Pernambuco, arriving at the latter place on March 12. They will take passage by the local mail steamers to Ceara, at which place they will arrive about March 20

The Brazilian Government are willing to place a war vessel at the disposal of the foreign expeditions to observe the eclipse, and it is hoped the English observers will be able to avail themselves of the privilege thus gracefully offered The station selected is at Para Cura, on the coast about forty miles west of Ceara, and the party will rely upon obtaining any necessary help from the Brazilian authorities and from local assistants The observers will return from Pernambuco by the Royal Mail steamer due to leave there on April 22, and expect to be in England on May 5

The objects of the expeditions are—

(1) To obtain visual photometric measures of the light of the corona

(2) To obtain photographs of the corona with the four-inch lenses of a little over sixty inches focus belonging to Captain Abney, which were successfully used in Egypt (1882), Caroline Island (1883), Granada (1886), and Salut Isles (1889), in order to continue the series

(3) To obtain enlarged photographs of the corona with small photographic action, so as to show details of the structure of the brightest parts, *i e* those nearest the sun

(4) To measure the photographic intensity of the light of the corona, by direct comparison with standard intensity scales placed on the margins of the plates used for the negatives to be obtained under sections 2 and 3

(5) To obtain photographs of the spectrum of the corona. These spectra will be obtained on three different plans —

(*a*) With integrating spectroscopes, where no collimator is used and the prism or prisms are placed directly in front of the object glass of the photographic camera

(*b*) With ordinary slit spectroscopes, the slit being arranged as a radius of the sun

(*c*) With ordinary slit spectroscopes, the slit being arranged as a tangent to the sun's limb

The first of these objects will be attempted only at the African station; Prof. Thorpe and his assistant, Mr Gray, making the observations Their equipment will consist of a six-inch Simms equatorial of seventy-eight inches focus (lent from Greenwich) fitted with special photometric apparatus lent by Captain Abney The observations will be made on essentially the same plan as that pursued by Prof Thorpe at Hog Island, near Granada, in 1886, separate portions of the corona being compared with a standard glow lamp by means of a Bunsen photometer An integrating box for measuring the total coronal light with as little light from the sky as possible, and an ordinary Bunsen's bar photometer will also be used, these being entrusted to officers of the gunboat.

As regards objects 2, 3, and 4, duplicate apparatus has been arranged for use at the two stations

A photoheliograph mounting from Greenwich has been lent for Brazil, and an exactly similar instrument from South Kensington for Africa. On each of these mountings a specially designed new double tube will be fixed An Abney lens will be mounted in one compartment of each of these tubes, and this, with a focal length of sixty inches, will give pictures on the scale of rather more than half an inch to the moon's diameter In the other compartment a four-inch Dallmeyer photoheliograph lens will be mounted in combination with a specially-constructed two-and-a-half-inch Dallmeyer negative lens of eight inches negative focus; this arrangement giving, with a total length of sixty-eight inches, pictures on the scale of over one-and-a-half inches to the moon's diameter. This latter arrangement is essentially the same as that of Dallmeyer's new telephotographic lens. It will be so arranged that the ratio between the photographic effect of the Abney lens and the new combination will be as 10 : 1

Special plate holders have been made to fit the double tubes, each of these plate holders carrying two plates, which will be exposed simultaneously to the images formed by the Abney lens and the enlarging combination. The six separate exposures, giving twelve photographs, will be so arranged that the longest exposed pictures with the enlarging combination will have received the same photographic action as the shortest exposed pictures with the Abney lens The whole of the pictures will thus form a continuous series, all the short exposures in the series having a direct enlargement of three diameters

In Brazil Mr Taylor will take charge of this double instrument, and in Africa the similar instrument will be entrusted to Sergeant Kearney On the night before the eclipse intensity scales for object 4 will be impressed by the use of standard lights and specially-constructed scales kindly supplied by Captain Abney on all the plates to be exposed to the corona The plates will be developed at the stations as soon as convenient after the eclipse, experience on previous occasions, both by English and American observers, having shown that it is impossible to repack undeveloped plates after exposure in the tropics, and bring them home without serious deterioration

Similar spectroscopic work is to be carried out at the two stations For the integrating spectroscope in Africa Mr. Fowler will use a six-inch objective prism with a six-inch photographic lens of about nine-feet focus, mounted on an equatorial stand, belonging to Prof J Norman Lockyer, and kindly lent for the expedition At the Brazilian station Mr Shackleton will use two three-inch prisms in front of a three-inch photographic lens of about two-feet focus; the spectroscope, which belongs to South Kensington, being arranged horizontally and used with a ten-inch heliostat, also lent by the Science and Art Department Very short exposures will be given at each station at the commencement and end of totality, so as to obtain, if possible, the very numerous bright lines which have been observed in the chromosphere, and exposures of from 5 to 45 seconds will be given during totality

In Africa the radial and tangential slit spectroscopes will be mounted together on the Corbett equatorial stand lent from Greenwich, the spectroscopes used belonging to the Royal Society Mr Fowler and Sergeant Kearney will erect and adjust these instruments, but the actual exposure, which will extend through the whole of totality, will be made by an officer of the gunboat who will be placed in charge of the instrument In Brazil the radial and tangential slit spectroscopes will be mounted horizontally and used with a second ten-inch heliostat lent by the Science and Art Department The erection and adjustment will be made by the observers, but the actual exposure during totality will be entrusted to a local assistant. Orthochromatic plates will be used for all the spectroscopic work, the spectra obtained extending from above D into the ultra-violet.

Briefly summarised, the English programme is as follows —

In Africa —Prof T E Thorpe, assisted by Mr Gray and local assistance—Photometric measures of the visual Intensity of the corona with the equatorial photometer, the integrating photometer, and the bar photometer; Mr Fowler—The six-inch integrating spectroscope; Sergeant Kearney—the Abney and Dallmeyer coronographs, local assistance—the radial and tangential slit spectroscopes.

In Brazil:—Mr Taylor, the Abney and Dallmeyer coronographs, Mr Shackleton, the three-inch two-prism integrating spectroscope, local assistance, the radial and tangential slit spectroscopes

It is not yet decided whether one of the 20-inch mirrors of 45-inches focus specially constructed to photograph the faint extensions of the corona during the eclipse of 1889 (December 21–22) will be taken to Africa If so it will be entrusted to a local assistant. It was originally intended to use one of these in Africa, and it was hoped that one would be used by the Harvard College

Observatory party, which is to occupy a station in Chili, but Prof W. H Pickering writes that difficulties of transport will prevent him from taking the 20-inch mirror he has at Arequipa to the Harvard station, and owing to this and to the already large programme of the English party in Africa there is some doubt whether they will take one of the mirrors April being the middle of the rainy season in Brazil, it is not deemed advisable to send one of the mirrors to that station

The duration of totality at Para Cura is four minutes forty-four seconds, the altitude of the sun being between 70° and 80° At Fundium the totality lasts four minutes eight seconds, the altitude of the sun being about 54°

The Joint Eclipse Committee having arranged the expeditions and the general scheme of work, final details as to the actual operations have been left to a sub-committee consisting of the Astronomer Royal, Captain Abney, Mr H H Turner, Prof Thorpe, Mr A Taylor, and the secretary, Dr Common Prof Lockyer, previous to leaving England for Egypt, determined the exposures to be given by Messrs Fowler and Shackleton with the integrating spectroscopes These, with the final instructions to observers drafted by the sub-committee, will be published in due course

At present very few details are available as to the actual work to be undertaken by foreign observers The Harvard College Observatory expedition to Chili has already been mentioned Prof Schaeberle, of the Lick Observatory, has already started for Chili, and will use a six-and-a-half-inch equatorial, a five-inch horizontal photoheliograph of forty-feet focus, and a Dallmeyer portrait lens He will be assisted by Mr Gale, an amateur, from Paddington, N S W A Chilian party will also observe the eclipse in Chili

At Para Cura there will probably be two or three American parties, one being announced as probably under Prof H S Pritchett, from Washington University, St Louis, and another will probably be brought to that station by Prof David P Todd A Brazilian party will also observe The Bureau des Longitudes, Paris, are sending a complete expedition to Joal, in Africa, under MM. Deslandres and Bigourdan, the latter observer having already started for his station The work undertaken will be to obtain photographs of the corona and of its spectrum M de la Baume Pluvinel will also go to Joal to photograph the corona. At present we have not heard of any Italian expedition, but it is hoped that Prof. Tacchini will be able to arrange to observe the eclipse

A TAYLOR

MEASURE OF THE IMAGINATION[1]

THE first perceptible sensation is seldom due to a solitary stimulus Internal causes of stimulation are in continual activity, whose effects are usually too faint to be perceived by themselves, but they may combine with minute external stimuli, and so produce a sensation which neither of them could have done singly. I desire now to draw attention to another concurring cause which has hitherto been unduly overlooked, or only partially allowed for under the titles of expectation and attention. I mean the Imagination, believing that it should be frankly recognised as a frequent factor in the production of a just perceptible sensation. Let us reflect for a moment on the frequency with which the imagination produces effects that actually overpass the threshold of consciousness, and give rise to what is indistinguishable from, and mistaken for a real sensation Every one has observed instances of it in his own person and in those of others Illustrations are almost needless, I may, however, mention one as a reminder; it was current in my boyhood, and the incident probably took place not many yards from where I now stand Sir Humphrey Davy had recently discovered the metal potassium, and showed specimens of it to the greedy gaze of a philosophical friend as it lay immersed in a dish of alcohol to shield it from the air, explaining its chemical claim to be considered a metal All the known metals at that time were of such high specific gravity that weight was commonly considered to be a peculiar characteristic of metals, potassium, however, is lighter than water The philosopher not being aware of this, but convinced as to its metallic nature by the reasoning of Sir Humphrey, fished a piece out of the alcohol, and, weighing it a while between his finger and thumb, said seriously, as in further confirmation, "How heavy it is!"

In childhood the imagination is peculiarly vivid and notoriously leads to mistakes, but the discipline of after life is steadily directed to checking its vagaries and to establishing a clear distinction between fancy and fact Nevertheless, the force of the imagination may endure with extraordinary power and be cherished by persons of poetic temperament, on which point the experiences of our two latest Poet-Laureats, Wordsworth and Tennyson, is extremely instructive. Wordsworth's famous "Ode to Immortality" contains three lines which long puzzled his readers They occur after his grand description of the glorious imagery of childhood, and the "perpetual benediction" of its memories, when he suddenly breaks off into—

> "Not for these I raise
> The song of thanks and praise,
> But for those obstinate questionings
> Of sense and outward things,
> Fallings, from us, vanishings," &c

Why, it was asked, should any sane person be "obstinately" disposed to question the testimony of his senses, and be peculiarly thankful that he had the power to do so? What was meant by the "fallings off and vanishings," for which he raises his "song of thanks and praise"? The explanation is now to be found in a note by Wordsworth himself, prefixed to the ode in Knight's edition Wordsworth there writes—"I was often unable to think of external things as having external existence, and I communed with all I saw as something not apart from, but inherent in, my own immaterial nature Many times while going to school have I grasped at a wall or tree to recal myself from this abyss of idealism to the reality At that time I was afraid of such processes. In later times I have deplored, as we all have reason to do, a subjugation of an opposite character, and have rejoiced over the remembrances, as is expressed in the lines 'Obstinate questionings,' &c." He then gives those I have just quoted

It is a remarkable coincidence that a closely similar idea is found in the verses of the successor of Wordsworth, namely, the great poet whose recent loss is mourned by all English-speaking nations, and that a closely similar explanation exists with respect to them. For in Lord Tennyson's "Holy Grail" the aged Sir Percivale, then a monk, recounts to a brother monk the following words of King Arthur —

> "Let visions of the night or of the day
> Come, as they will, and many a time they come
> Until this earth he walks on seems not earth,
> This light that strikes his eyeball is not light,
> The air that smites his forehead is not air,
> But vision," &c.

Sir Percivale concludes just as Wordsworth's admirers formerly had done: "I knew not all he meant."

Now, in the *Nineteenth Century* of the present month

[1] Extract from a lecture on "The Just-Perceptible Difference," delivered before the Royal Institution, on Friday, January 27, by Francis Galton, F R S. We hope to give next week an extract on "Optical Continuity"

[2] Knight's edition of Wordsworth, vol. iv p. 47

Mr Knowles, in his article entitled "Aspects of Tennyson," mentions a conversational incident curiously parallel to Wordsworth's own remarks about himself — "He [Tennyson] said to me one day, 'Sometimes as I sit alone in this great room I get carried away, out of sense and body, and rapt into mere existence, till the accidental touch or movement of one of my own fingers is like a great shock and blow, and brings the body back with a terrible start'"

Considering how often the imagination is sufficiently intense to stimulate a real sensation, a vastly greater number of cases must exist in which it excites the physiological centres in too feeble a degree for their response to reach to the level of consciousness So that if the imagination has been anyhow set into motion, it shall as a rule originate what may be termed *incomplete* sensations, and whenever one of these concurs with a real sensation of the same kind, it would swell its volume

This supposition admits of being submitted to experiment by comparing the amount of stimulus required to produce a just perceptible sensation, under the two conditions of the imagination being either excited or passive

Several conditions have to be observed in designing suitable experiments The imagined sensation and the real sensation must be of the same quality, an expected scream and an actual groan could not reinforce one another Again, the place where the image is localised in the theatre of the imagination must be the same as it is in the real sensation This condition requires to be more carefully attended to in respect to the visual imagination than to that of the other senses, because the theatre of the visual imagination is described by most persons, though not by all, as internal, whereas the theatre of actual vision is external The important part played by points of reference in visual illusions is to be explained by the aid they afford in compelling the imaginary figures to externalise themselves, superimposing them on fragments of a reality The visualisation and the actual vision fuse together in some parts, and supplement each other elsewhere

The theatre of audition is by no means so purely external as that of sight Certain persuasive tones of voice sink deeply, as it were, into the mind, and even simulate our own original sentiments The power of localising external sounds, which is almost absent in those who are deaf with one ear, is very imperfect generally, otherwise the illusions of the ventriloquist would be impossible There was an account in the newspapers a few weeks ago of an Austrian lady of rank who purchased a parrot at a high price, as being able to repeat the Paternoster in seven different languages She took the bird home, but it was mute. At last it was discovered that the apparent performances of the parrot had been due to the ventriloquism of the dealer An analogous trick upon the sight could not be performed by a conjuror Thus he could never make his audience believe that the floor of the room was the ceiling

As regards the other senses the theatre of the imagination coincides fairly well with that of the sensations. It is so with taste and smell, also with touch, in so far that an imagined impression or pain is always located in some particular part of the body, then if it be localised in the same place as a real pain, it must coalesce with it

Finally, it is of high importance to success in experiments on Imagination that the object and its associated imagery should be so habitually connected that a critical attitude of the mind shall not easily separate them. Suppose an apparatus arranged to associate the waxing and waning of a light with the rising and falling of a sound, holding means in reserve for privately modifying the illumination at the will of the experimenter, in order that the waxing and waning may be lessened, abolished, or even reversed It is quite possible that a person who had no idea of the purport of the experiment might be deceived, and be led by his imagination to declare that the light still waxed and waned in unison with the sound after its ups and downs had been reduced to zero But if the subject of the experiment suspected its object he would be thrown into a critical mood, his mind would stiffen itself, as it were, and he will be difficult to deceive

Having made these preliminary remarks, I will mention one only of some experiments I have made and am making from time to time, to measure the force of my own imagination It happens that although most persons train themselves from childhood upwards to distinguish imagination from fact, there is at least one instance in which we do the exact reverse, namely, in respect to the auditory presentation of the words that are perused by the eye It would be otherwise impossible to realise the sonorous flow of the passages, whether in prose or poetry, that are read only with the eyes We all of us value and cultivate this form of auditory imagination, and it commonly grows into a well developed faculty I infer that when we are listening to the words of a reader while our eyes are simultaneously perusing a copy of the book from which he is reading, that the effects of the auditory imagination concur with the actual sound, and produce a stronger impression than the latter alone would be able to make

I have very frequently experimented on myself with success, with the view of analysing this concurrent impression into its constituents, being aided thereto by two helpful conditions, the one is a degree of deafness which prevents me when sitting on a seat in the middle rows from following memoirs that are read in tones suitable to the audience at large, and the other is the accident of belonging to societies in which unrevised copies of the memoirs, that are about to be read, and usually in monotones, are obtainable, in order to be perused simultaneously by the eye Now it sometimes happens that portions of these papers, however valuable they may be in themselves, do not interest me, in which case it has been a never-flagging source of diversion to compare my capabilities of following the reader when I am using my eyes, and when I am not The result depends somewhat on the quality of the voice, if it is a familiar tone I can imagine what is coming much more accurately than otherwise It depends much on the phraseology, familiar words being vividly re-presented Something also depends on the mood at the time, for imagination is powerfully affected by all forms of emotion The result is that I frequently find myself in a position in which I hear every word distinctly so long as they accord with those I am perusing, but whenever a word is changed, although the change is perceived, the new word is not recognised Then, should I raise my eyes from the copy, nothing whatever of the reading can be understood, the overtones by which words are distinguished being too faint to be heard As a rule, I estimate that I have to approach the reader by about a quarter of the previous distance, before I can distinguish his words by the ear alone Accepting this rough estimate for the purposes of present calculation, it follows that the potency of my hearing alone is to that of my hearing *plus* imagination, as the loudness of the same overtones heard at 3 and at 4 units of distance respectively, that is as about 3^2 to 4^2, or as 9 to 16 Consequently the potency of my auditory imagination is to that of a just perceptible sound as 16–9, or as 7 units, to 16 So the effect of the imagination in this case reaches nearly half-way to the level of consciousness If it were a little more than twice as strong it would be able by itself to produce an effect indistinguishable from a real sound

Two copies of the same newspaper afford easily accessible materials for making this experiment, a few words having been altered here and there in the copy to be read from

I will conclude this portion of my remarks by suggesting that some of my audience should repeat these experiments on themselves If they do so, I should be grateful if they would communicate to me their results

PROTOCERAS, THE NEW ARTIODACTYLE

LAST year the American Museum of Natural History established a department of mammalian palæontology for the purpose of securing and exhibiting collections from all the tertiary horizons of the west Dr J. L Wortman, well known by his discoveries while associated with Prof Cope, was put at the head of the field work, and under his direction explorations have already been made in the Laramie or Upper Cretaceous, and in three of the great divisions of the tertiary, namely, the Wasatch, the Puerco, and the Lower Miocene or White River

The discovery of the first example of *Palæonictis* found in America was mentioned in NATURE last year From the Puerco are brought remains of about 400 individuals, adding many new facts to the discoveries of Prof Cope From the Laramie are 400 of the small isolated teeth of the kind recently described by Prof Marsh. These are found by the writer to have a distinctly tertiary rather than mesozoic character, and while intermediate between the mesozoic and Puerco species, they decidedly resemble the latter *Meniscoëssus*, for example, about which there has been so much discussion, proves to be a plagiaulacid,

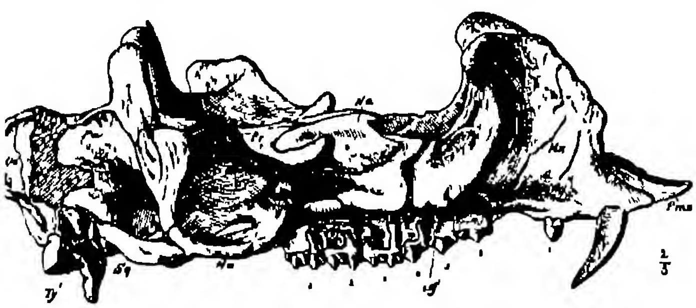

FIG 1 --Side view of skull

and also an ancestor of *Polymastodon*, which is thus shown to be a huge *Plagiaulax*, in which the fourth cutting premolar is reduced

By far the most perfect specimens have, however, been brought from the Lower Miocene, and here it appears that practically a new horizon has been developed, for the collection is full of fresh forms Many of these are new species intermediate between the true White River or *Titanotherium* fauna, and the Middle Miocene, but others are new genera, and represent distinct unrelated forms.

In this Lower Miocene collection are included portions of six skulls and the fore and hind feet of an Artiodactyle, of about the size of a sheep. The most complete skull is here figured exactly as found, and is seen at once to depart from all known Artiodactyles in many important characters. There are no less than four protuberances upon each side of the skull. Hindmost are two processes upon the parietals, which are placed upon the superciliary ridges as they diverge from the sagittal crest. These processes are close together and oval in section, reminding us of the posterior pair of horns in *Uintatherium* rather than of the conical or rounded horns found in the giraffes and some other Artiodactyles. Their position upon the parietal bones is also peculiar. The superciliary ridges extend outwards into two widely projecting plates of bone, which curve upwards above the orbits; these plates are upon the frontals, and the frontals also bear a pair of small conical processes just behind their junction with the nasals But even more exceptional than these parietal and frontal processes are the great vertical plates rising from the maxillaries, slightly recurved, and reaching the full height of the parietal protuberances Seen from above, these plates are found to be not in contact, but to enclose a long deep cleft, representing the anterior narial opening This is bridged over posteriorly by the nasals, which, as shown in the second figure, are extremely abbreviated Correlated with the development of these processes are a number of strong ridges, which form supporting buttresses for the horns These extend, as above described, from the sagittal crest outwards, also from the anterior margin of the orbit forwards This lateral maxillary ridge, as it may be called, terminates in a process just above the infraorbital foramen, and this process, although small, seems to illustrate the remarkable tendency of this little skull to develop osseous projections at every avail-

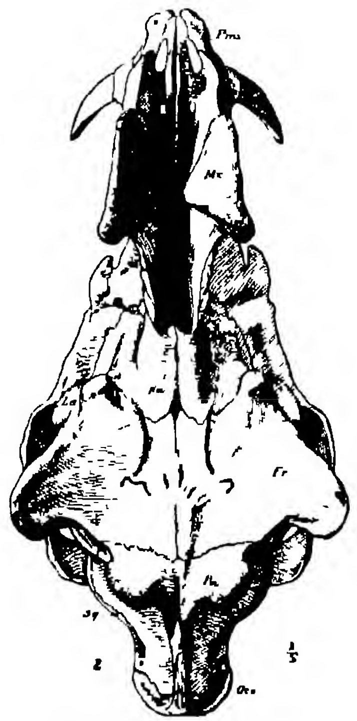

FIG 2 —Top view of skull

able point The character of these projections is different from that found elsewhere among the Artiodactyla, they are not horn-cores, neither are they similar to the processes upon the parietals of the giraffe. The development of these multiple bony protuberances suggests the skulls of Sivatherium, Tetraceros, and other eastern ruminants, but the proportions of the skull are wholly different The olfactory chamber, which is usually so expanded in the Artiodactyla, is here extremely reduced, the nasals barely reach beyond the middle line of the skull

Up to this point the study of the skull appeared to present an entirely new form, but later the other skulls were removed from the matrix, and among them one was found with small canine teeth, entirely lacking all the processes upon the frontals, and giving indications that those upon the maxillaries were either absent or comparatively small The parietals were unfortunately missing, but the idea at once suggested itself that this might be a female skull Two years ago Prof.

Marsh described a small Artiodactyle with a pair of small conical horn-cores upon the parietal bones, which he named *Protoceras celer*, expressing the opinion that it represented a new family Upon the supposition that this type might also be a female of the same species to which the heavily-horned type belonged, the second skull was taken to the Yale Museum, and carefully compared point by point It proved to be identical in every respect In this way the discovery was made that in *Protoceras*, as in so many other Artiodactyles, the male and female skulls differed widely from each other in their cranial armature The male was as described above, the female exhibits merely a pair of very small conical processes upon the parietals, with perfectly smooth frontals, and maxillaries either of the normal type or with smaller protuberances than in the male

The dentition at first suggests relationship to *Tragulus* and *Hyomoschus* The premaxillaries are edentulous as in the ruminants, but in the lower jaw there are four small teeth shaped liked incisors, the outermost of which represents the canine The upper canines are large,

FIG 3—Front view of Skull

pointed, and recurved The molar teeth are of the short-crowned, or brachyodont type, with a distinctly crescentic pattern

The structure of the feet also suggests the Tragulines, in the fact that the fore-foot has four well developed toes, while the hind-foot has two toes with the lateral pair very much reduced As in the *Tragulidæ*, the fore foot and probably the fore limb was very much shorter than the hind foot and limb The hind foot, moreover, shows a tendency to co-ossification both in the metatarsals and in the union of the navicular and cuneiform with the cuboid In many details, however, the feet present marked differences from the older and more recent Tragulines. The oldest of the Tragulines, moreover, is *Leptomeryx*, a contemporary of *Protoceras*, which has an entirely different skull and foot structure.

Taking all these facts together, we are led to support Prof. Marsh's conjecture, based upon the comparatively hornless female skull, that this Artiodactyle represents a new family, the *Protoceratidæ*. We know absolutely nothing either of the ancestors or successors of this type, and this is another illustration of the fact which is constantly being impressed upon us, that our fossil-bearing strata still contain a great number of forms which are at present wholly unknown and unsuspected.

HENRY F OSBORN.

HENRY F. BLANFORD, F.R.S

MR. H. F BLANFORD, whose death was noticed in last week's NATURE, was born in Bouverie Street, Whitefriars, in the City of London, in 1834. He was one of the students who entered the Royal School of Mines at its commencement in 1851, and after distinguishing himself by taking the first Duke of Cornwall's Scholarship, he studied for a year at Freiberg in Saxony In 1855 he and his brother, Mr W T Blanford, received appointments on the Geological Survey of India, and they landed in Calcutta at the end of September in that year Mr H F Blanford remained on the Geological Survey till 1862, when he resigned, his health having suffered from the exposure incidental to geological surveying in India His most important work whilst engaged on the Survey was the examination of the cretaceous beds of the neighbourhood of Trichinopoly, his classification of which, founded to a considerable extent on palæontological data, has been thoroughly confirmed by Dr F. Stoliczka's well known description of the fauna. Mr Blanford had previously, during his first season's work in India, by separating the Talchir strata, with their remarkable boulder bed, from the true coal-bearing, or Damuda rocks, taken the first step in what for so long was one of the most difficult tasks set before the Indian Geological Survey—the stratigraphical arrangement of the complex of beds subsequently known as the Gondwana system

On leaving the Geological Survey he was offered a post in the Bengal Educational Department, and from 1862 to 1874 he was one of the professors of the Presidency College, Calcutta. Soon after 1862 he began to take a keen interest in meteorological questions, and after being for some time a member of a meteorological committee nominated by the government, he was, in April 1867, appointed Meteorological Reporter to the Government of Bengal, and placed in charge of an office established with a twofold purpose, to give storm warnings for the protection of shipping and to collect and record systematic meteorological observations throughout the Bengal presidency Within a short time one most important result was obtained, the meteorological conditions under which cyclones originated in the Bay of Bengal were definitely ascertained, and it became practicable to say when a storm was a probable event, and in what part of the Bay it might be expected, and when a cyclone was impossible, although high winds might prevail Meantime the various observatories of the country were being brought into order, and the observations rendered systematic

In 1874 the Government of India became convinced of the necessity for placing all the meteorological observatories in India in communication with a central office, and Mr Blanford was finally transferred from the educational staff of Bengal and made chief of the new meteorological department, with the official designation of Meteorological Reporter to the Government of India. The new post involved much travelling to visit out-stations, in order to ensure the exact comparison of barometers and other instruments. The organisation of the new department, however, progressed rapidly, and in a few years a series of papers from Mr. Blanford's pen on rainfall, wind directions, and other meteorological phenomena gave evidence to all interested in the science that valuable additions to it were being made by the Indian observations The peculiar geographical conditions of India render its meteorology unusually simple, and of great scientific and practical importance An admirable illustration, both of the peculiarity of Indian meteorology and of the practical results yielded by accurate observations, is afforded by the fact that no sooner was the whole system in working order, than it was found practicable some time before the commencement of the monsoon season, and of the rainfall, upon which in many provinces plenty or scarcity of food depends, to prepare a forecast of the approaching season, and to warn the Government of a possible deficiency of rain in particular parts of the country The forecasts prepared have been found remarkably accurate.

Mr. Blanford retired from the Indian Service in 1888,

and has since resided at Folkestone Of late his health has gradually given way, and he died on January 23, at the age of fifty-eight He was elected a Fellow of the Royal Society in 1880, and was an honorary member of several foreign meteorological societies He was President of the Asiatic Society of Bengal in 1884–85

That he was a man of considerable intellectual power is shown by the somewhat unusual range of scientific questions on which he has left works and papers Besides his geological and meteorological reports, he wrote for the Indian Geological Survey descriptions of the *Nautilidæ* and *Belemnitidæ* of the South Indian cretaceous rocks, and he assisted the late Mr J W Salter in describing the Palæontology of Niti He was also author of several papers on recent mollusca, and amongst his works are two treatises, one on the "Physical Geography of India," largely used as a text-book in Indian schools, and the other "An Elementary Geography of India, Burma, and Ceylon," published as one of Macmillan's Geographical Series

NOTES

WE learn from Sydney that steady progress is being made with the Macleay Memorial Volume, and that it will probably be ready for issue about the end of March

AN announcement comes from Chicago that Mr Eadweard Muybridge, who, it will be remembered, visited this country some time since on behalf of the University of Pennsylvania, will give at intervals, from May to October, in the "Zoopraxographical Hall of the Exposition," a series of lectures on the science of animal locomotion, especially in its relation to design in art.

ON Thursday next, February 9, Prof Patrick Geddes will begin, at the Royal Institution, a course of four lectures on the factors of organic evolution, and on Saturday week, February 18, Lord Rayleigh will begin a course of six lectures on sound and vibration

A TRANSLATION of Prof Weismann's new work on "The Germ-plasm," recently noticed in NATURE, will appear in the "Contemporary Science Series" in the course of a few weeks

LAST week a deputation, representing the New Decimal Association, the Chambers of Commerce and Trades Unions, as well as various scientific institutions, waited upon Sir William Harcourt, Chancellor of the Exchequer, to urge the Government to adopt the decimal and metrical system of weights, measures, and coinage, or to appoint a committee of inquiry into the subject Mr S Montagu, M P, as president of the New Decimal Association, having introduced the deputation, said that forty years ago there was great apathy upon the subject, but since then there had been inquiries by Select Committees and Royal Commissions into the question of the decimal currency, and though the reports of those bodies were satisfactory, no action had followed The system had been adopted in Germany, Austria-Hungary, and Scandinavia; and in England there was now a good popular demand, such as Mr. Goschen said six years ago he was waiting for Men of science like Lord Kelvin, Sir Henry Roscoe, and Sir John Lubbock, and educationists like Sir Philip Magnus and Dr. Gladstone desired the reform in order to economise brain-power; representatives of commerce desired it to assist them in their competition with rival nations; and the working classes were awake to the fact that years of labour were wasted by their children being compelled to learn that which could be rendered unnecessary. Several members of the deputation, including Sir Philip Magnus, having spoken, Sir William Harcourt replied He said that every one who reflected on the question must see the great advantages which attach to the decimal system But the practical difficulties in the way of the proposed change seemed to him for the present to be insurmountable A decimal system was introduced into Europe by the French Revolution That was a time when the whole of society was cast into the melting pot, and they changed, not only their notation, not only their metrical system, but the names of the months and the days of the week The change in Germany took place, not in quiet times, but as a result of the unification of Germany He believed that even in the United States of America the change was made consequent upon the establishment of the Federal system He did not think that the habits of the people could be altered in quiet times This applied very much to the measures as well as to the coinage Sir William was ready as an individual to play his part in forwarding the progress of the decimal system and the metrical system, but the Government could do nothing in the matter The people would have to be prepared for so great a change

IT is worth noting that instruction in the principles of the decimal and metric systems is daily given in public elementary schools, and that this labour—as Mr J H Yoxall, secretary of the National Union of Teachers, has pointed out in a letter to the *Times*—is imposed upon the children without hope of practical good to the community Mr Yoxall contends that if an Act of Parliament were to fix a date of five or ten years hence at which the decimal system should come into legal operation, the work of the schools and the precaution of the mercantile classes would by that time sufficiently prepare the way

A DESTRUCTIVE earthquake occurred on Tuesday morning at the town of Zante Several houses were totally destroyed, many more were partially wrecked, and there is hardly a building in the town which has not sustained damage in one form or another The roof of the prison collapsed during the earthquake, and the guards had to be doubled to prevent the escape of the prisoners The hospital was also so seriously damaged that it was deemed expedient to remove the patients The shocks, which were general, were renewed again and again, and the whole population was thrown into a state of panic

DURING the past week the temperature over these islands has been fairly high, the daily maxima often exceeding 50°, notwithstanding a temporary fall, amounting from 12° to 14° in Scotland and the midland counties of England, on Friday, accompanied by much fog in the south and east of England, while the air has been decidedly humid, the readings of the dry and wet bulb thermometers frequently showing little or no difference These conditions have been due to deep depressions arriving from the Atlantic and passing in close proximity to our western and northern coasts In those parts gales have been of almost daily occurrence, and on Sunday they extended as far as the English Channel. Rain has been frequent, but generally the fall has not been heavy, and the sky has generally been overcast and dull, although on Saturday the weather over the south of England was unusually bright and fine. The *Weekly Weather Report* of January 28 shows that the temperature exceeded the mean in all districts, the greatest excess being 4° in Scotland Bright sunshine also exceeded the mean in some parts of Scotland and in the eastern portion of England, but in other parts of these islands there was a deficiency.

A MAP showing lines of equal magnetic declination for January 1, 1893, in England and Wales, has been very carefully prepared by Mr. W. Ellis, and published as a supplement to

the *Colliery Guardian* of January 6, 1893 The explanatory text states that, as before, the work depends on the magnetic surveys of Profs Rucker and Thorpe Mr Ellis gives a table showing the relation between the diurnal variation of magnetic declination and sun-spots, as determined from the magnetic observations made at the Royal Observatory, Greenwich The general mean at epochs of minima of sun-spots is 7 4 minutes, and at epochs of maxima 11 4 minutes of arc, and other magnetic elements show a similar relation The period between successive epochs of maxima or of minima of sun-spots is well known to be on the average about 11 years, and the author points out the curious fact that the interval between the minimum and maximum is on the average 4½ years, whilst from maximum to minimum it is 7 years The relation existing between sun spot maxima and minima and the diurnal magnetic variation has led many meteorologists to seek for some similar connection with meteorological phenomena, but Mr Ellis states that no such relation has yet been conclusively established

THE report of the administration of the Meteorological Department of the Government of India in 1891–92 shows continued activity and efficiency in all departments of the work, and bears testimony to the interest taken both by the public and by the *employés* The number of observatories maintained by the Government at the end of the year was 165 As regards the actinometric work, an unusual amount has been done, owing to the favourable state of the weather, and the results have been forwarded to the Solar Physics Committee in London The rainfall data are published month by month, and a large number of unsatisfactory rain gauges has been replaced by new ones A larger amount of work under the head of marine meteorology has been done than in any previous year, several clerks are continually employed in collecting data from ships entering the various ports, and these observations have been utilised in preparing daily weather charts of the whole Indian area for a portion of the year The systems of storm and flood warnings have been continued as in previous years, and observations have been taken in certain forests, in order to throw light on the influence of forest growth in modifying the distribution and amount of rainfall, a report upon this subject will shortly be prepared. Among the other papers being prepared for publication we note one on the relation between sun-spots and weather as shown by meteorological observations taken on board ships in the Bay of Bengal during the years 1855 to 1878

AT the meeting of the Royal Botanic Society of London on Saturday a plant of the Sisal hemp (*Agave rigida*) was shown from the Society's gardens. This plant is now extensively grown in the Bahamas and Central America for its fibre The secretary said that until lately, with the exception of two or three fibre plants, as hemp and cotton, commerce depended upon wild plants for its supplies, but so great was the demand now for fibres for papermaking and other uses that it had been found necessary to grow them specially

THE Slojd Association of Great Britain met on Saturday to receive the annual report, to elect officers, and to appoint an examining body It was agreed that "Sloyd" should be substituted for "Slojd" in the name of the Association The system of handiwork which the society is seeking to introduce into schools has already been pretty extensively adopted in this country, especially in the north of England. Mr Harris stated at the meeting that it was being received with approval in many different parts of the world. He had received communications from Napier, New Zealand, and Lahore, India, as to its adoption in these places.

AN American writer who was present at the Galileo Festival in Padua gives a very interesting account of it in the New York *Nation* He refers to the speeches delivered in Italian by Sir Joseph Fayrer and Prof George Darwin, to which we have already alluded "They were," he says, "much appreciated by the audience 'Parla bene!' 'Pronunzia bene!' one heard murmured in tones not devoid of surprise" The greatest orator of the occasion, according to this writer, was Prof Schmurlo of Dorpat, in Russia. "The type of the lonely and ungainly scholar in appearance, he nevertheless spoke a few phrases so ultra-Italian in the ingenious gracefulness of their turn, that the audience went fairly wild with delight"

THE latest instalment of the Transactions of the Institution of Engineers and Shipbuilders in Scotland contains an interesting paper, by Mr E G Carey, on the bridges of the Manchester Ship Canal. The paper is fully illustrated The author notes that practically the whole of the bridge-work for this canal has been constructed in Glasgow from Scotch steel.

THE Smithsonian Institution has issued as one of its bulletins a full and very useful bibliography of the published writings of George Newbold Lawrence, the well-known ornithologist The work has been done by Mr L. S Foster, who gives also a short sketch of Mr Lawrence's career Mr Lawrence's collection of bird skins is of great scientific value It includes about 8000 specimens, and contains some three hundred types of new species of birds The collection was deposited in the American Museum of Natural History, New York City, in May 1887 Mr Foster says that the beneficial influence of the labours of Mr Lawrence, with pen and pencil, on the progress of American ornithology, has been great and undisputed It is particularly among the avifauna of the West Indies, Mexico, Central and South America, that his most strenuous efforts have been exerted

IF we may trust a statement made on the authority of the Tokyo News Agency, it is not surprising that Japan is unwilling to be deprived of the privilege of fishing on the Korean coast The number of Japanese boats engaged in the fishery is said to be no less than upwards of four thousand four hundred, of which about eighteen hundred have licenses Their annual take averages from a million and a half of *yen* to two million value, and it is estimated that with more diligence and improved methods they might easily bring this figure to three or four millions

IT is rather surprising that tobacco has been so little cultivated in Australia. The *Agricultural Gazette* of New South Wales, we are glad to see, has taken up the matter, and in its November number devotes to it a comparatively long and interesting paper. The writer of the article thinks that the climate of New South Wales is admirably suited to the growth of tobacco, and hopes that a sufficient quantity of it may hereafter be produced not only to satisfy local demands, but to open up a large and lucrative export trade

ONE of the curious survivals of ancient prejudices in India is the intense dislike with which many high caste Hindus regard sea voyages. It is even disputed whether a Brahmin who takes a sea-voyage does not lose caste The Maharaja of Mysore has not only emancipated himself from this strange notion, but is doing his best to overcome it in others. He lately made a voyage to Calcutta, and took with him a number of orthodox Brahmins, as well as Brahmin officials of state.

MR WALTER HOUGH, of Washington, notes in *Science*, that among the collections from Mexico, Central and South America, exhibited in the Columbian Historical Exhibition at Madrid, he observed a number of oblong polished blocks of hard stone of unknown use, averaging 3½ inches in length, 2¾ inches in width, and 1¼ inches in thickness. The broad sur-

faces of these stones are plane, bearing a number of grooves parallel to the length, forming ridges like those seen on Polynesian tapa mallets The implements resemble closely, he thinks, those used by many different peoples in beating out fibrous bark for clothing, paper, &c Mr Hough suggests that they may have been used for purposes of this kind in prehistoric times, and that they may give some insight into the manufacture of the paper on which the Mexican codices are painted.

MUD GORGE, on the Hurnai route to Quetta, has been giving much trouble to the engineers engaged in the construction of the new railway. Landslips are frequent, and an unusually bad one has occurred within the last few weeks On this occasion the hill, according to the *Pioneer Mail*, slipped in such a way "as to lift the rails bodily up and turn them over, sleepers uppermost" The mountain is said to be a great porous mass of clayey soil with large boulders imbedded therein, and it sucks in moisture like a sponge. After heavy rain it begins to move downwards, and even in dry weather disintegration goes on with disastrous results to the railway New fissures are reported to have appeared hundreds of yards up the slopes above the line, and each of these indicates that thousands of tons of earth and boulders will sooner or later find a lower level A committee of experts has been appointed by the Indian Government to examine the mountain thoroughly, and the *Pioneer Mail* truly says that "if they succeed in devising a means to conquer it they will achieve a notable feat in engineering"

DR LOW, President of Columbia College, New York, has been stating in the American *Educational Review* his impressions as to the condition and tendencies of the higher education in the United States One of the points on which he strongly insists is that a general college training should be considered necessary before students begin their University education in theology, law, and medicine "The prophetic eye," he says, "can even now discern the day when a college education will be a condition precedent for entrance into the professional schools of the American university This will not mean that only college-trained men will make good practitioners in law or medicine, for example, nor that only college trained men are entitled to a professional education. It will rather mean, I think, that the university will then have fully realised its own obligation to the country to send forth into professional life, in all parts of the land, men of a thorough and wide equipment."

ARCHÆOLOGISTS have observed that in Greek statues the male eye is strongly arched, while the female eye has rather a flattened surface; and referring to accounts by the older anatomists who have affirmed such a difference to exist, they have seen in this a fresh proof of the exact observation of nature by the ancient Greeks. The rule is not without exceptions, for the cornea in the Zeus of Otricoli has quite a flat form Herr Greef recently set himself (*Archiv fur Anat*) to inquire whether such a sexual difference actually exists, and from individual measurement of the radius of the cornea in the horizontal meridian, he gets an average of 7·83 mm for men, and 7·82 mm for women (Donders gives 7 858 and 7 799), so the difference is so small as to be imperceptible to the naked eye. Measurement of other dimensions gave but minute differences also The author concludes that the Greeks (from artistic motives) did not in this case follow nature.

THE difference between the aspect of the sky at full moon and the clear and deep azure observed on a moonless night is explained by M. Clémence Royer in his "Recherches d'Optique Physiologique et Physique" on the basis of some observations made by M. Piltschikoff. In studying the polarising action of the moon on the atmosphere, the latter found that the proportion of polarised light in the nocturnal sky diminishes continuously from the time of the full moon up to that of the new moon, when it becomes zero, subsequently to increase again until the time of full moon There appears to be a struggle between the polarised light of the moon and the so-called natural light of the stars, and the proportion of polarised light sometimes reaches 62 per cent The diffusing power of the atmosphere necessarily varies with the relative proportions of natural and of polarised light, since the latter is not capable of reflection in all directions Hence we see why very serene but moonless nights may yet be relatively very clear, and the sky of a beautiful sombre blue, whereas the white light of the moon, reflected, diffused, and polarised, tends to give the sky a tint of a paler and somewhat greyish blue

AT the last annual meeting of the American Association of Official Agricultural Chemists, the Proceedings of which have just been issued, Mr. N T Lupton referred in his presidential address to the immense phosphate beds in the south-western part of Florida Last winter a visit was paid to some of the localities where deposits are found, and samples were collected for analysis They were of two varieties, which may be called hard and soft The hard variety consists of boulders of moderately hard rock, some of immense size, cemented together with white clay A white and friable mass resembling kaolin is occasionally found This is probably produced by the natural disintegration of the hard rock by rolling, attrition, or concussion The deposits vary in thickness A depth of 20 or 30 feet is not uncommon, and even a thickness of 50 feet has been found As some, especially foreign, manufacturers object to buying phosphates which contain over 3 per cent of oxides of iron and aluminium, large quantities of these materials have accumulated at the mines. A few manufacturers, aware of the agricultural value of South Carolina floats, have established mills in Florida for pulverising these soft aluminous deposits, which are sold to farmers for use without conversion into soluble phosphates. Experiments are now in progress on the Alabama Experiment Station, under control of the chemist, to determine the chemical composition and agricultural value of these soft phosphates when used alone with cotton seed and with cotton seed meal If decomposing organic matter, as is believed, renders insoluble phosphates available as plant food to any considerable extent, Mr. Lupton thinks that the question of cheap phosphates will be solved, and that the American farmer will be enabled to purchase fertilisers at a much less cost than at present

MESSRS W. H ALLEN AND CO have issued the thirty-seventh thousand of Dr M. C Cooke's "Manual of Structural Botany" The book is intended for the use of classes, schools, and private students.

THE February number of *Natural Science* includes, among other things, articles on some problems of the distribution of marine animals, by Otto Maas, on Pasteur's method of inoculation and its hypothetical explanation, by G. W. Bulman, the industries of the Maoris, by J W Davis, some recent researches on insect anatomy, by G H. Carpenter, parasites on algæ, by G. Murray; the underground waste of the land, by H B. Woodward, Owen (concluded), by A. S. Woodward, and the restoration of extinct animals.

THE following are the arrangements for science lectures at the Royal Victoria Hall during February —Feb 7, Mr J Scott Keltie, on Africa and its people, Feb 14, Mr. E Wethered, on interesting objects under a microscope; Feb 21, Mr. J. T. Leon, on breathing and burning, Feb. 28, Dr H. Forster Morley, on chemistry of life

THE additions to the Zoological Society's Gardens during the past week include seven Azara's Opossums (*Didelphys azaræ*)

from the Argentine Republic, presented by Mr Hill, a Rough Terrapin (*Clemmys punctularia*) from Guiana, presented by Mr J J Quelch, C M Z S; an American Milk Snake (*Coluber eximius*) from Tennessee, presented by Miss Winifred M. Middleton, a Virginian Eagle Owl (*Bubo maximus*) from South America, deposited, two Mouflons (*Ovis musimon*, ♂ ♀) from Corsica, received in exchange

OUR ASTRONOMICAL COLUMN

THE NAUTICAL ALMANAC FOR 1896 —The new superintendent of the *Nautical Almanac* office has introduced a much-needed reform into the first almanac, that for 1896, issued under his direction The state of the *British Nautical Almanac* has long been severely criticised as being far from the best possible for navigational purposes both in form and contents, and by no means satisfactory from the astronomical standpoint A letter addressed by the Shipmasters' Society to Dr Hind, the late Superintendent, in November 1891, pointed out the advantage to navigators which would be offered by a work published at a popular price, and without that astronomical information which is of no use to sailors Many low priced almanacs are published, indistinctly printed, and having occasional errors in the figures, and an official trustworthy book was very desirable In consequence of this representation the almanac is now published in two forms—as the complete almanac of former years, price 2*s* 6*d*, and as Part I of the *Nautical Almanac*, specially suited for the use of sailors, price 1*s*

The complete almanac has been revised and added to, many of the recommendations of the *Nautical Almanac* Committee of the Royal Astronomical Society, which reported to the Admiralty in 1891, having been adopted The small short period terms of nutation have been tabulated, and, corresponding to that, additional day numbers are added so as to enable computers to include those small terms in the star corrections. The catalogue of stars from which the moon culminators and stars occulted by the moon are obtained has been revised and enlarged, and the mean places of the stars of this catalogue, which are used during the year, are also included The elements of the occultations are given in a revised form similar to that adopted in most of the other astronomical ephemerides, so that the circumstances of an occultation for any position on the earth's surface can be computed with facility There has been a general revision of the constants used

The small almanac has been arranged by Mr Downing in conference with the Hydrographer As the guiding principle in publishing this was the minimum of change in the parts of the almanac which were to be extracted and published separately, there is still much in the volume that is not needed by sailors, but the omission of which would have necessitated the setting up of fresh type and much extra work at the *Nautical Almanac* office The monthly part is printed unaltered, and consequently contains the sun's and moon's latitude and longitude, which are not required by sailors. The noon ephemerides for the brighter planets, Venus, Mars, Jupiter, and Saturn, the catalogue of mean places of stars, as well as the apparent places of the nine stars used for lunar distances, the eclipse section and the tables for navigation are then given There is no doubt that the issue of this smaller work will confer a real benefit on the shipping community, and that it will soon win its way to popularity

In announcing these changes to the Royal Astronomical Society, Mr Downing expressed the hope of being able, through the economy of time effected by international co-operation in some of the work of the office, to make considerable future additions to the almanac without increasing the burden of the British taxpayer The duplicate work done at Berlin, London, Paris, and Washington involves much waste of energy which might be more usefully expended: and as a step towards this, Mr Downing, last summer, arranged with Prof. Newcomb, of Washington, to co operate in some of the work of their respective almanacs, and the Admiralty have consented to this. It is to be hoped, in the interests of astronomy and of navigation, that the scheme may be greatly extended.

ECLIPSE PHOTOGRAPHY.—The results obtained by M. de la Baume Pluvinel at Salut Isles in 1889 (as given in his lecture which appeared in NATURE last week), when he photographed the corona with photographic actions varying from 185 to 13, and found the photographic action of 30 the most satisfactory, do not agree with those of the English expedition obtained at the same time and place The photographic actions on the plates exposed with the 20-inch mirror of 45-inches focus, by the late Father Perry, varied from 19 75 to 790· as calculated by the formula given by M de la Baume Pluvinel, and in every case increase of photographic action gave greater extension of the corona. Mr Rooney's plates, with the 4-inch lens of 61 inches focus, had been subjected to photographic actions varying from 1 11 to 177 77, and agreed with Father Perry's in giving greater extension with every increase of photographic action. The English results certainly justify the conclusion that greater photographic action is necessary to photograph those faint extensions of the corona which have been seen, but have hitherto eluded attempts to photograph them

Mr Burnham's experiments, alluded to by M Pluvinel, do not assist us in this question A certain absolute amount of light is necessary to give *any* appreciable photographic effect on the plate, and this seems to be the chief difficulty in obtaining photographs of the external corona. In Mr Burnham's experiments he had too much light and had to cut down the exposure in order to get faint contrasts, but there was never any question of not having sufficient light to obtain any photographic effect. Captain Abney finds (Phil. Trans vol clxxx. A, page 314) that an abrupt change of ½ per cent in the intensity of light can be detected on a photograph, hence we may look upon a negative as a drawing built up of 200 different shades Over exposure will of course prevent such faint contrasts as ½ per cent being detected, and under exposure will enable fainter contrasts to be seen, *so long as the limit of minimum exposure necessary to produce any photographic effect is passed*, but the evidence from the English expedition renders it extremely probable that even with the largest photographic action used this limit was not actually reached with the faintest extensions of the corona

COMET HOLMES.—Dr. F Cohn, writing about this comet from the Observatory in Konigsberg on January 17, finds (*Astronomische Nachrichten*, No 3146), with a 6-inch heliometer and a magnification of 65 times, that the nucleus is exactly as a star of the 8th magnitude The correction to the ephemeris given below is, as he has deduced, $\Delta\alpha = -0\ 3s$, $\Delta\delta = -6''$

Dr R. Schorr, of the Hamburg Observatory, puts the nucleus down on the same date as a 7 2 magnitude star with a small nebulosity about it of 5" diameter, but on the 18th he found the comet showed a much larger coma, a measurement giving 87" The stellar nucleus was also estimated as 7 5 magnitude of a diameter 2"

The ephemeris of this comet is from Prof Schulhof's calculations (*Astronomische Nachrichten*, No 3140) —

THE ANDROMEDES.—Although Mr. Maclair Boraston was unfortunate in having bad weather on the nights of November 13 and 14 last, thus obscuring the Leonids, yet the magnificent shower of the Andromedes that he describes in *Astronomy and Astrophysics* for January should have recompensed him somewhat for "the great elevation of the radiant point, combined with a cloudless tropical sky, the absence of moonlight and the unobstructed view of the complete hemisphere, afforded the *ne plus ultra* of astronomical requirement." Observing in

longitude 72° west and latitude 17° north, between 11h 48m and 5h. 48m G.M.T., he deduced the radiant point from 70 short track meteors, and four coincident stationary ones, giving its position as R.A. 28°, decl +36°. Counts being taken at intervals for areas of 60°, about 18 meteors per minute were recorded, thus making a total number of 108 for the entire hemisphere in one minute, or 6480 per hour. As this fall went on continuously for six hours without any sign of the numbers diminishing, we have the number of meteors 38,880, which Mr. Boraston says must certainly be a minimum, as many faint and rapid ones must have escaped notice. A further observation at 8h 48m showed that the action was still being kept up, thus increasing this number to about 60,000. During this display it was remarked that the meteors appeared much brighter when distant from the radiant point than in its vicinity.

A NEW METHOD OF PHOTOGRAPHING THE CORONA.—M. H. Deslandres, in the *Comptes Rendus* of January 23, describes a method of photographing the solar corona without the aid of absorbing media. Sunlight is allowed to fall directly on a system of two identical prisms with parallel and inverted faces placed at a distance apart, such that only a portion of the diverging band from the first is intercepted by the second. After passing through the latter, the rays by recomposition give rise to a well defined coloured image of the sun's disc. On displacing the prisms in a line perpendicular to the line joining them, the image assumes different colours, and on moving them along it, the range of colours intercepted is made to change. The prisms may be replaced by gratings. In a series of experiments carried out during the autumn, nine successive impressions of the sun's image were taken, ranging from the C line till far into the ultra violet. The object was to find the region where the light emitted by the corona showed the greatest photographic difference from that of the diffused sunlight in the atmosphere. As a matter of fact, a halo distinctly separated from the diffused sunlight showed itself on some of the negatives, especially in the ultra violet region, which very probably represented the corona. But to confirm this, simultaneous exposures at different, especially elevated, stations ought to be made, if possible during a total eclipse.

GEOGRAPHICAL NOTES

THE February number of the *Geographical Journal*, in addition to two important papers read before the Royal Geographical Society, and already reported in NATURE, contains a brilliant account by Mr. Conway of the crossing of the Hispar Pass. The views of mountain scenery were bewildering in their extent; from the foot of the valley an unbroken glacier was in sight, stretching downward from the pass forty miles distant. This unrivalled ice-stream was covered for the lower twenty miles with moraines. From the pass a vast snowfield, surrounded by magnificent rock aiguilles, was seen to lie below, and from this the Biafo glacier descended. From the end of the Hispar glacier to the end of the Biafo glacier was a distance of eighty miles, forming the longest snow-pass in the world outside the Polar regions. Mr. Stephen Wheeler communicates a paper on Mendez Pinto, whose early travels in the East seem to have been unduly discredited.

IT is announced that the eminent geographical author M. Elisée Reclus has accepted a professorship in the University of Brussels, and will commence his work there by a course of lectures on comparative geography.

MR. ASTOR CHANLER's expedition to Lake Rudolf, by the Tana, has reached Hameye, the Ibea Company's post at the head of navigation on the Tana—a position accessible in five weeks from the coast, to which camels, oxen, donkeys, and horses can be safely taken. Lieutenant Hohnel, who is attached to the expedition, finds that Commander Dundas has placed the Tana from 20 to 22 minutes of longitude too far west, and he has searched in vain for the mountain ranges reported by Dr. Peters.

IN a recent journey of some duration in the Sakalava plain in the north west of Madagascar, M. Emile Gautier (according to the *Annales Géographiques*) found the soil everywhere to consist of a stiff red clay, weathered into steep sided lumps and chasms overlying sedimentary rocks, but quite similar in colour and character to the red clay which covers the volcanic rocks of the plateau. M. Gautier believes that this clay is identical with the laterite of the Deccan.

MAJOR LEVERSON, the British Commissioner for the delimitation of the frontier between the British South Africa Company's territory and the Portuguese possessions, has returned to this country, after having carried out extensive surveys and made considerable rectifications in the map of a strip of country stretching from the north east corner of the Transvaal northward to Massikesse. The position of the latter point was fixed as 18° 15′ 33″ S., 32° 51′ 24″ E.

MR. MACKINDER gave the second lecture of his course on History and Geography, under the auspices of the Royal Geographical Society, on Friday evening, when he discussed the road to the Indies, showing how the desert route, which led to the growth of Palmyra, was superseded by the ocean route after the successful rounding of the Cape of Good Hope. The theatre of history in ancient times was the region enclosed between the pine forests of northern Asia and the Indian Ocean, divided into separate worlds by a double belt of deserts and steppes.

THE GROWTH OF ELECTRICAL INDUSTRY

ON Friday last Mr. W. H. Preece, F.R.S., delivered before the Institution of Electrical Engineers his inaugural address as President. He said he had completed his fortieth year of continuous service in developing the practical applications of electricity for the use and convenience of man, and it appeared to him that he could not better repay the high compliment the Institution had conferred on him by electing him, for the second time, to be its President than by surveying and criticising the growth of the various branches of electrical industry with which he had been more or less associated during that long period. In the course of his address he dealt with telegraphy, submarine telegraphy, lightning protection, railway signalling, telephony, domestic applications, electro-chemical industry, electric lighting, power transmission, electric traction, and theoretical views of electricity.

Speaking of telegraphy, Mr. Preece said:—The instrument that we have principally developed in England is the automatic fast speed apparatus, based on a principle of preparing messages for transmission by punching, devised by Alexander Bain in 1848, and improved in its mechanical details by Mr. Augustus Stroh in 1866. This has been my special pet, and with the electrical assistance of Mr. J. B. Chapman, and the mechanical skill of Mr. J. W. Willmot, all the ills that telegraphs are heir to have been routed, and the practical speed of working has been multiplied more than six fold. It has been one long continual contest between patient observation, inventive skill, careful experiment, and technical acquirement on the one hand, and resistance, electrostatic capacity, inertia (electro-magnetic and mechanical), bad insulation, impure materials, imperfect workmanship, &c., on the other. But we have, step by step, won all along the line. 75 words per minute have become 500; a possible 130 has become an actual 600. Duplex automatic working over cable lines is possible, and modes of working have been introduced that were thought at one time chimerical and impossible.

The results to which I have referred have not been attained without very special attention to questions of construction and maintenance of the wires, both aerial and submarine, and a very complete system of test is now applied both before and after every line is completed. In the early days of telegraphic communication very rough and crude tests were applied, and the condition of the lines caused serious difficulties; but at the present day we must ascertain the purity of the metal employed, its mechanical strength, its electrical resistance and capacity, its insulation resistance, and the relationship between the latter and the conductor resistance, as well as its speed value. The employment of copper as the conductor suspended on poles in place of iron, which was inaugurated at my instigation in 1884, by a very costly experiment between London and Newcastle, has had a material influence in increasing the speed of working and improving telegraphy. This is due not only to its reduced resistance, but to the absence of electro-magnetic inertia in a long, single suspended copper wire. All our long important telegraphic circuits are now built with copper.

One of the arguments used against the proposed transfer of the telegraphs to the State was the notion that invention would not be fostered by a Government department. This has been entirely falsified. Telegraphy has been advanced in this country

more rapidly by the British Post Office than by any private undertaking, and we have certainly shot ahead of our smart cousins on the other side of the Atlantic, from whom, however, I am proud to say, I learnt so much on my visits in 1877 and 1884. Their engineers are looking to us to develop their inventions, and we have done so They cannot always get them taken up in the States Diplex, quadruplex, and multiplex telegraphy are importations from them, but they have been improved in our service by our own developments, and have now become the staple and the standard modes of working No one has done more to effect this object than Mr M Cooper.

An accident in the drafting of the Act of Parliament of 1868-69 transferring the telegraphs from the hands of private companies to that of the State, has led to a tremendous development of newspaper reporting in England Few people are aware of the immense business done for the press The growth of press messages is shown in the fact that 21,701,968 words paid for in 1871 have grown in 1891 to 600,409,000—an average of nearly 2,000,000 words per day

When Mr Gladstone spoke at Newcastle, at the National Liberal Federation, in 1891, 390,778 words were signalled to different parts of the country This kind of business is not, however, confined to the Post Office The Exchange Telegraph Company, which commenced operations in 1872, working under the license of the Postmaster General, has in London over 800 instruments at work (120 being in newspaper offices), distributing a daily average of 3,381,134 words to various receiving instruments adapted to the requirements of the respective services The financial intelligence, for example, being transmitted over instruments furnished with type wheels containing the various fractions most in use in Stock Exchange quotations The latest form of this instrument prints at the rate of forty words per minute General and parliamentary intelligence are distributed to the clubs over column printers, and legal, sporting, and Parliamentary news to newspapers on specially fast tape printers, capable of delivering, in the hands of skilled operators forty five full words per minute to any number of subscribers simultaneously The news transmitted is chiefly commercial and financial, amounting to 2,775,000 words per day.

To return to the purely State telegraphy Some idea of the growth of the general telegraphic business of the country may be gathered from the following statement, which gives the total number of messages paid for in each year —

1852	211,137
1869	6,830,000
Transfer took place in 1870	
1882	31,345,861
1892	70,215,439

In the course of his review of the history of submarine telegraphy, Mr Preece said —By far the greatest cable corporation in the world is the Eastern Telegraph Company, whose system of 25,376 miles stretches from Cornwall to Bombay, connects the northern and southern shores of the Mediterranean with Malta, and joins up the various other islands of the Mediterranean and the Levant This company, in conjunction with the Eastern Extension and the Eastern and South African Companies, also gains access to Australia and New Zealand on the one hand, and to the Cape of Good Hope on the other, the combined mileage reaching a total of no less than 47,151 This enormous system has all grown up within, practically, the last 23 years

The form of cable has practically remained unaltered since the original Calais cable was laid in 1851 Various sizes of core and armour, and various modes of protection from decay, have been used to suit different routes, but the cable of to day may be said to be typically the same as that used in the English Channel in 1851, and in the Atlantic in 1865

The first cable had gutta-percha as a dielectric, and it is still almost exclusively used for submarine cable core; but the manufacture has so improved in the last twenty years that a core having an insulator weighing 150 lbs per naut, which then had a dielectric resistance of some 250 megohms a naut at 75° F, can now be obtained, giving 2000 megohms at the same temperature. Indiarubber is creeping in, owing to the high price and scarcity of gutta-percha

Next to strong tides, rocky bottoms, anchors, and shallow water, the greatest enemy to submarine cables, more especially in the tropics, has proved to be the teredo of various species; but this depredatory worm has been utterly routed by covering the gutta percha core with a lapping of thin brass tape laid on spirally A remarkable thing about this little insect is that, whereas twenty years ago it was practically unknown in our English waters, it has now gradually spread all round our coasts, with the exception, perhaps, of the North Sea A new cable about to connect Scotland and Ireland is being served with brass tape

With the cables has grown up a fleet of telegraph ships to lay and maintain them' In 1853 the *Monarch*, belonging to the Electric Telegraph Company, was the only ship permanently employed as a repairing telegraph ship, now, in 1893, the cable fleet of the world numbers no less than 37, of which seven belong to Government administrations and the rest to private companies, the Eastern Telegraph Company heading the list with five vessels

Perhaps the most remarkable history of a cable is the following —In 1859 the light cables laid in 1853 from Orfordness to Holland were picked up and replaced by a heavier one A few nauts were sold to the Isle of Man Telegraph Company, and had an extra sheath laid on This cable was submerged between that island and St Bees, where it remained until 1885, when it was replaced by a three-core cable It was again put under water in 1886 as part of the cable between Uist and Harris, in the Hebrides, where it still lies, as good as ever The durability of submarine cables is remarkable That laid between Beachy Head and Dieppe in 1861 is still working, and that laid between Beachy Head and Havre in 1870 has broken within the last month for the *first* time

Despite the enormous growth of submarine cables during these forty-two years, there would appear to be plenty of scope for still further extension The Pacific still remains untouched, and the project is at the present time under consideration to connect our possessions in North America with those in Australia.

The following is the passage relating to telephony —I had the good fortune in 1877 to bring to England the first pair of practical telephones They had been given to me in New York by Graham Bell himself After a series of experiments, I brought them before the British Association meeting, which was held that year at Plymouth Who at that time could have imagined that the instruments, which were then but toys, would, within sixteen years, have become a necessity of commercial, and almost of domestic, life? Yesterday the number of telephones in actual use may pretty safely be put down at a million!

During 1878 Edison devised his carbon transmitter, and Prof Hughes presented his "microphone" to the world These inventions made the telephone a practical instrument of vast commercial importance It may be said to have sprung into existence well-nigh perfect, and the fewness of the actual improvements on the Bell receiver and the Hughes microphone is scarcely more astonishing than the immense number of fruitless attempts at improvement that have been made Even now the original instruments are not easily beaten

The institution of telephone exchanges has led to a development of systems of switching that might fairly be considered a special study in themselves, and the demand for communication between distant places has necessitated the application of much special attention to the method of constructing lines and of arranging circuits.

It is in this latter field that I have been a diligent worker, and the application of the so called "K R" law has proved of material benefit in connection with the problems of long-distance telephony It is a law which implies that the number of signals that can be transmitted per second through any circuit depends solely on the capacity (K) and the resistance (R) of the circuit It is very much the fashion to deny the accuracy of the K R law This is probably the result of ignorance of its meaning or of its interpretation. Some speak of it as empirical, others scoff at it as imaginary, and some sneer at it as an impossible law; but it is a law that has determined the dimensions and speed of working of all our long submarine cables, it determines the number of arms a circuit can carry on the multiplex system, the speed attainable with the Wheatstone system, and the distance to which it is possible to work quadruplex; it is a law that has enabled us to bring London and Paris within clear telephone speech of each other, and which will probably before the year is out enable Dublin and Belfast to speak to London—a message

of peace to Ireland as solid and substantial as any promised political proposal.

The New York and Chicago trunk line is 950 miles long, and it is built with 435 lbs (or No 8 S W G) copper wire. This wire gives a resistance of 2.06 ohms per mile, which is easily verified, but it is said by Mr Wetzler to have a capacity of 0.0158 microfarad per mile, which cannot be verified, and which is absurdly high. 0.0158 microfarad was a measurement made by me in England on an old line, but I have frequently pointed out that owing to the use of earth wires the capacity of our English lines is very much greater than that of American lines. Mr Edison discovered this in 1872 when he came to England to introduce his automatic system. Moreover, I have also pointed out that induction still further diminishes this capacity. The Paris circuit does not exceed 0.005 microfarad per mile. I should estimate the Chicago circuit at 0.004 microfarad per mile, and the K R at 7500, which gives a result that quite accords with the opinions that I have heard expressed by those who have tried the two circuits as to the relative efficiency of the Paris and Chicago lines. My American friends would have done better if they had used thicker wire. I should have specified 600 lbs per mile, but if it had been in England I should have used 1000 lbs, for we cannot dispense entirely with cables and underground work as they have done in the States, and the increased capacity introduced must be compensated for by reduced resistance. As a matter of fact, I once proposed 1200 lbs wire for a circuit between London and Berlin—a distance of 760 miles, including a cable 55 miles long.

The beneficial effect of induction as a negative capacity is observed when working a circuit telegraphically with automatic high-speed apparatus. Thus, on two copper wires 450 miles long, making 900 miles altogether, the speed on each single wire was 120 words per minute, and on metallic circuit—

Loop *viâ* different routes	120 words per minute
,, on same poles	150 ,, ,,

So that the improvement effected by induction was 25 per cent.

There is no difficulty in measuring R of a metallic loop. The Wheatstone bridge determines it at once. There is more difficulty in obtaining K. It cannot be measured directly. But with a metallic loop of copper, partly overhead and partly underground, there are several modifications required, due to electrostatic and electro magnetic induction, which are at present beyond the reach of formulæ, and render it difficult to determine the capacity except approximately from the telephonic effects themselves. Thus the capacity on the London-Paris circuit proved to be only one-half of that obtained by calculation, and every long circuit will require its own K to be determined by comparison with an empirical K R scale. Such a scale I have determined by careful experiment on artificial cables.

I have recently devised a new form of cable which will probably quadruple the rate of telegraph working to America, and I may say with all confidence that there is no theoretical reason whatever why we should not converse between London and every capital in Europe, while it is not impossible to speak even across the Atlantic.

With regard to electric lighting, Mr Preece said that many efforts are being made to utilise the waste forces of nature in producing electric currents for the economical supply of the light. In America, Scotland, Switzerland, Italy, and, indeed, wherever waterfalls are available, electric plant is being installed to convert the energy of the fall into the useful form of electricity. At Tivoli, near Rome, a fall of 165 feet is used to work six turbines of 350 horse-power each, giving 2100 horse power in all. Six high-pressure alternators working in parallel send electrical energy at over 5000 volts pressure to Porta Pia, near Rome, 14.8 miles from Tivoli, through four stranded copper conductors, each having a diameter of 13mm, and bunched into one metallic loop, giving a total resistance of 4 ohms. At Porta Pia the 5000 volts are reduced to 2000, and the currents are distributed to several substations spread over the city, where they are again lowered to the safe pressure of 102 volts, at which voltage the current is supplied to the consumer on the three-wire system. There are 600 arcs and 30,000 glow lamps in use in Rome, but they are not all supplied from Tivoli. Mr Preece inspected this installation only a few days ago, and found everything working smoothly and efficiently under the able guidance of Prof. Mengarini.

Water power abolishes the coal bill, but it must be remembered that the cost of maintenance of machinery and of the erection and upkeep of conductors limits the distance to which the energy of falling water can be economically transmitted. The proposal to light New York by currents generated at Niagara is at present financially absurd. It is doubtful whether it will be commercially advantageous at Buffalo 30 miles away, but it is certain that at Tivoli it can be so applied with advantage and profit.

There is much water power in this country that might be usefully employed. At Worcester it is proposed to use the water of the Teme, a tributary of the Severn, to supply electrical energy to the city—an experiment that will be watched with considerable interest, for the use of water power will solve the difficulty occasioned by light loads during the small hours and daylight. Keswick and Lynton have already been so served, but on a small scale only. There are many towns whose public streets could be brilliantly illuminated by the streams running past them, but there is much fear and distrust to be removed from the minds of our local magnates, and a considerable amount of education necessary before the public will receive the full value of the gifts that nature so freely places at its disposal, and the engineer so thoroughly converts into a utilitarian form.

The following are some extracts from the passage in which theoretical views of electricity are discussed —

In the Presidential address which I delivered to the Society of Telegraph Engineers and Electricians in 1880, I took the opportunity to formulate the theoretical views of electricity that I had acquired at the feet of Faraday. It is not given to every boy to have his great ambitions realised. One of my ambitions as an earnest listener to Faraday's simple and delightful lectures was to be his assistant, and in almost the last investigation he undertook on electric induction in underground wires it was my privilege to see much of him, and to prepare many experiments for him. Early in 1854, at his wish, I carried out for Mr Latimer Clerk certain experiments on the comparative effect of increments of voltage in increasing the rate of transmission of signals through long telegraph circuits. It was found that variation of voltage had no effect. Currents from 31 and from 500 cells sent through 768 miles of gutta percha covered underground wire showed precisely the same velocity. These experiments were sent by Faraday to Melloni, who had prompted the wish, and Melloni ("Faraday's Researches," vol iii page 577) remarked "The equal velocity of currents of various tensions offers a fine argument in favour of the opinion of those who suppose the electric current to be analogous to the vibrations of air under the action of sonorous bodies." This is to be found in the very last contribution inserted in the greatest work ever published on our science, "Faraday's Experimental Researches in Electricity."

Faraday's views were subsequently expounded and extended by Maxwell, who said "Faraday, in his mind's eye, saw lines of force traversing all space, where the mathematician saw centres of force attracting at a distance, Faraday saw a medium where they saw nothing but distance, Faraday sought the seat of the phenomena in real actions going on in the medium, they were satisfied that they had found it in a power of action at a distance impressed on the electric fluids" (Maxwell, "Electricity," vol i page 10).

Since that period I have never regarded electricity as anything else but as a form of energy, and its effects as modes of motion of the molecules of matter and of the ether that fills all space, and during my long apprenticeship of forty years I have never examined one experiment or considered one fact that was not explicable on this theory.

Electricity is energy which is transmitted by matter and through space by certain disturbances the result and the equivalent of work done, and in certain orderly and law regulated forms, called "electro magnetic waves." It is not difficult to conceive the ether carved or the molecules of matter swayed or excited in definite periodic waves. A molecule is subject to all kinds of motion—translation, oscillation, rotation upon its own axis, and revolution about some external axis. Clausius (*Pogg Ann*, clvi p 618) suggested that the atoms or groups of atoms constituting a molecule revolve around one another similarly to planets, and are sometimes nearer to and sometimes further from each other. The difference between the infinitely great and the infinitely little is only one of degree. The motions of the solar system and that of a molecule of water are similar. These motions are imparted to and transmitted by

the ether, and they are taken up again by matter One kind of wave gives us light, another radiant heat, another magnetism, and another electrification The rate at which these waves move is the same, viz 30,000,000,000 centimetres, or 192,000 miles, per second It is only their form and their frequency that differ Matter and ether are subject to strains, currents, vortices, and undulations, and every single electro-magnetic phenomenon can be compounded of or reduced to one or other of these mechanical disturbances Rotation in one direction gives positive electrification . rotation in the opposite direction gives negative electrification A whirl in one direction gives us north magnetism , in another direction, south magnetism Hertz, the experimental exponent of Maxwell's views, has shown the existence of electro-magnetic waves, and has proved their reflection, refraction, and interference The rate of their propagation is the same in ether, air, and conducting wires

The most recent discoveries and deductions are all in accordance with this mechanical theory J J Thomson's views that at high temperatures, in the act of dissociation, all gases, and Dewar and Fleming's conclusion that at low temperatures—in fact, at the absolute zero of temperature—all metals become perfect conductors, might almost have been predicted Hysteresis and Foucault losses are mere wastes of energy, due to molecular friction or to internal work done on the molecules, assisted by bad design and impure material , but, being measurable and comprehensible, their reduction to a minimum has become possible and actual

It is a misfortune that a beautiful hypothesis like Maxwell's electro magnetic theory of light has been discussed almost solely by mathematicians Its consideration has been confined to a small and exclusive class It has not reached the public , and this is to be regretted, for, after all, it is the many, and not the few, that determine the acceptance or refusal of a theory The existence of the ether is now thoroughly comprehensible Light is now regarded as an electro-magnetic disturbance The eye is an extremely sensitive and delicate electro magnetic instrument The difference between luminous, thermic, and electro-magnetic waves is one of frequency and form We thus have to consider the propagation of these waves not only in the conductor and in the dielectric in the direction of the circuit itself, but in the ether at right angles to this direction The former produces currents in the conductor, and the latter induction and secondary effects in contiguous conductors. Thus it is easy to see why electric and magnetic lines of force are at right angles to each other, and each of them perpendicular to the line of propagation of the primary electro magnetic wave, and why the transversal disturbances are secondary waves of electro magnetic energy which can be transformed into electric currents of opposite direction whenever contiguous conductors lie in their path so as to be cut by these lines of force in the proper direction Induction is thus mere transformation of energy whose direction and magnitude are easily calculated

It is by following out this line of thought that I have recently succeeded in sending messages by Morse signals across the Bristol Channel between Lavernock and Flat Holm, a distance of 3 1 miles The electro magnetic disturbances were excited by primary alternating currents in a copper wire, 1237 yards long, erected on poles along the top of the cliff on the mainland The radiant electro magnetic energy was transformed into currents again in a secondary circuit, 610 yards long, laid along the island The strength of these secondary induced currents complied almost exactly with calculations. The results attained, the apparatus used, the precautions taken to separate effects of induction from effects of conduction , the elimination of mere earth currents from electro magnetic disturbances in air, will form the subject of a separate paper, for their proper consideration would be too tedious for an address I allude to them now only to illustrate the existence of one of the greatest proofs of the truth of a theory, viz the practical development and verification of a conclusion predicted from mere theoretical considerations

The oscillatory character of the discharge of a Leyden jar, which was discovered by Henry in 1842, is an admirable proof of this molecular theory If two jars, precisely similar as regards capacity and circuit inertia, be placed near each other with their planes parallel, and one of them is charged and discharged, the other responds sympathetically, as do two similarly pitched tuning-forks when one is excited Professor Oliver Lodge, who has made this field his own, has shown that by varying the capacity of the jars and the inertia of the circuit, oscillations can be produced to give any required rate of oscillation from one to 300 millions per second

In a room or theatre, when these discharges are excited, it is a common thing to see sympathetic sparks upon the spangled walls, and among the metallic objects scattered about The whole place is an electric field, which is violently disturbed at every spark, and everything which is "syntonised," as Oliver Lodge calls it, to the main discharge, responds in this way

It is impossible to account for these effects, which are all cases of transformed kinetic energy, except on the mechanical theory which I have advanced We have a source of disturbance, we have energy transmitted in waves, we have wave transformed into disturbance again Energy passes through its various stages by the motion of matter and the action of the ether Everything is accounted for and nothing is lost Waste energy only means energy in the wrong place

YEZO AND THE AINU

TWO papers on recent travels in the Island of Yezo were read to the Royal Geographical Society on Monday evening Prof J Milne, F R S , whose paper was read by the Secretary, made a journey to the north east of the island by sea in 1891, and returned by land, crossing Yezo almost through its centre He was accompanied by Mr John Revilliod, and travelled with a view to studying the volcanic geology of the regions Landing at Kushiro, interesting on account of the relics of pre Ainu inhabitants, and on account of its coal mines, they ascended the Kusuri river to Shibecha, where there is a great convict prison and sulphur refinery, the raw sulphur being obtained from the volcano Atosanobori, to which there is a railway twenty miles long In this locality the violence of the escape of steam from the boiling springs exceeds anything seen elsewhere in Japan, New Zealand, or Iceland A new road, thirty seven miles long, led from the volcano to Apashiri, on the north-east coast, where a factory for making matches has recently been erected, on account of the abundance of the white-stemmed poplar, the timber of which is much more readily worked in the fresh state than when dried A boat journey was made in a small dug out canoe under rugged cliffs from 500 feet to 1000 feet in height, for thirty miles to Shiritoki, where there is a great sulphur mine From some of the volcanic craters fused sulphur flows like lava, and crystallises in an almost pure state A trip from Nemuro to the nearer Kurile Islands was followed by the main feature of the journey, a ride from Yubets, on the north coast, up the Yubets river, across the watershed, and down the Ishikari river, to the west coast Groups of convicts working on the new roads, which are being made across the island, were almost the only people met with Vast groves of tall bamboo grass everywhere impeded the travellers, and insects of all kinds proved very troublesome There was little or no sign of larger animal life

Mr A H Savage Landor also read a paper He had wandered all round Yezo and up several of the largest rivers quite alone, and with no object save curiosity and the desire to study the Ainu at home The main part of his equipment was a great store of painting material, of which he made good use in portraying both the natives and the scenery of the island The Ainu accessible from Hakodate, who have been frequently visited and often described, are almost all Japanese half-breeds, and much influenced in customs and costume by their southern neighbours The Ainu of the interior and the more distant parts of the coast were very different The true Ainu villages are intensely filthy, and the vermin in them make life almost unsupportable to a stranger, minute black flies, which swarm in incredible hosts, being the worst The people, although good-humoured, are sunk in the most degraded savagery Their marriage customs seem to be summed up in unqualified promiscuity, the Ainu disclaiming any idea of being better than bears or dogs. The Ainu language is poor in words, and many of them show a curious resemblance to words of Anglo Saxon origin, *e g* *Chip*, for ship , *Do*, day , *Mukku*, music , *Pone*, bone , *Ru*, road ; *To*, two , *Wakka*, water. The religious beliefs of the Ainu can hardly be dignified by such a term ; they are merely superstitions. In travelling along the south-west coast there was often considerable danger from the waves washing over the narrow track which wound between the boulders on the beach Fog prevails along the east coast in summer, probably on account of the Kuro-Siwo encountering a cold current off the island. The upper Tokachi river was the

most remote part of Yezo visited, a region which had scarcely been traversed by the Japanese Here the Ainu were found to be more hairy than elsewhere, and to present many Aryan features in their general appearance One peculiar fact brought out by many measurements was the remarkable length of their arms. The measurement across the outstretched arms is always from three to five inches more than the height of the individual The future capital of Hokkaido (the name given to Yezo and the Kurile Islands collectively) is to be erected on the Kamikawa plain, in the very centre of Yezo, and roads are being pushed forward to connect it with all parts of the coast It will, when completed, take the place of the present capital, Sapporo According to Japanese maps, Mr Landor's journey extended to 5000 miles, but his own reckoning puts it as 3800, almost the whole distance was done on horseback

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD —By the death of Prof Westwood on January 2 the University lost one of the most learned of its members, and another link with the earlier study of science in Oxford is gone Prof Westwood became Hope Professor on the foundation of the chair by the Rev F W Hope in 1861, and afterwards devoted his time to the perfecting of the collection which Mr Hope bestowed on the University The collection, which has received considerable additions from other sources, including the Burchell collection, Wallace's types, &c, has attained somewhat unmanageable proportions, and its present quarters are too small for its proper display Whoever succeeds to the chair, it is to be hoped that suitable provision will be afforded to enable him to make the collection of more use to University studies than has hitherto been the case.

In November last an examination for a Radcliffe Travelling Fellowship, thrown open, *pro hac vice*, to all branches of natural science, was held, but the result has not yet been announced It is now announced that an examination will be held during this term for a second Radcliffe Fellowship, the subjects being strictly medical It is believed that the results of the two examinations will be published together at the end of this term There is some dissatisfaction at the delay in announcing the result of the first examination

Prof Ray Lankester has recovered from the illness which necessitated his absence from Oxford last term, and has resumed his lectures on the Vertebrata and a senior course on the Arachnida

The Mathematical Scholarships and Exhibitions have been awarded as follows —

Senior Mathematical Scholar, R C Fowler, B A, of New College

Proxime Accessit, S F White, B A, of Wadham College, to whom the Examiners have awarded Lady Herschell's book

Junior Mathematical Scholar, C B Underhill, Balliol College

Junior Mathematical Exhibition, J F. McKean, Hertford College

Proxime Accessit, W C. Childs, Corpus Christi College

The Duchess of Marlborough has bestowed on the Chemical Department the entire collection of chemical and electrical apparatus belonging to the late Duke The collection, which includes two exceptionally fine spectroscopes, delicate balances, &c., has been brought to the Museum from Blenheim, and forms a valuable addition to the Chemical Laboratory.

Mr. E. L. Collis, of Keble, is President, and Mr M D Hill, of New College, is Treasurer of the Junior Scientific Club this term, and Messrs C H H Walker, of University College, and T H Butler, of Corpus Christi, are respectively Chemical and Biological Secretaries The first meeting is held on Wednesday, February 1, when Mr J E Marsh exhibits some products of the electrical furnace, and Messrs. Finn and Fremantle read papers on East Africa and Hermaphroditism

At a meeting of the Biological Club, on Saturday last, Mr G. C Bourne read a paper on the influence of the nucleus on the cell.

CAMBRIDGE.—The Senate have resolved to appoint a Demonstrator in Palæozoology in connection with the Geological Department. He will have no stipend from the University, but will be remunerated from the fees paid by students.

Dr Allbutt, Regius Professor of Physic, Dr A MacAlister, Professor of Anatomy, and Dr Donald MacAlister, University Lecturer in Medicine, have been appointed to represent the University at the Eleventh International Medical Congress to be held at Rome in September next

Dr W H Gaskell has been appointed a member of the Special Board for Medicine, and Mr C T Heycock a member of the Special Board for Physics and Chemistry Dr Ransome, F R S, Honorary Fellow of Gonville and Caius College, Dr. Corfield, F R S, Professor of Hygiene and Public Health in University College, London, Dr J Lane Notter, Professor of Military Hygiene at Netley, and Dr Thorne Thorne, F R S, Medical Officer to H M Local Government Board, have been appointed Examiners in State Medicine for the Diploma in Public Health during the current year

Sir G G Stokes and Dr Hobson have been elected Examiners for the Adams Memorial Prize to be awarded in 1895

Mr E H Acton, of St John's, and Mr F H Easterfield, of Clare, have been approved as Teachers of Chemistry with reference to the regulations for medical and surgical degrees

SOCIETIES AND ACADEMIES

LONDON

Royal Society, December 15, 1892 —"Experiments on the Action of Light on *Bacillus anthracis*" By Prof Marshall Ward, F R S

It is abundantly evinced by experiments that direct insolation in some way leads to the destruction of spores of *Bacillus anthracis*, and in so far the results merely confirm what had already been discovered by Downes and Blunt in 1877 and 1878 [1]

From the fact that an apparent retardation of the development of the colonies on plates exposed to light was observed several times under circumstances which suggested a direct inhibitory action of even ordinary daylight, the author went further into this particular question with results as startling as they are important, for if the explanation given of the phenomena observed in the following experiments turns out to be the correct one, we stand face to face with the fact that by far the most potent factor in the purification of the air and rivers of bacteria is the sunlight The fact that direct sunlight is efficacious as a bactericide has been long suspected, but put forward very vaguely in most cases

Starting from the observation that a test tube, or small flask containing a few c c of Thames water with many hundreds of thousands of anthrax spores in it may be entirely rid of living spores by continued exposure daily for a few days to the light of the sun, and that even a few weeks of bright summer daylight —not direct insolation—reduces the number of spores capable of development on gelatine, it seemed worth while to try the effect of direct insolation on plate-cultures to see if the results could be got more quickly and definitely [2]

Preliminary trials with gelatine plate-cultures at the end of the summer soon showed that precautions of several kinds were necessary The direct exposure of an ordinary plate-culture to the full light of even a September or October sun, especially in the afternoon, usually leads at once to the running and liquefaction of the gelatine, and although the exposed plates eventually showed fewer anthrax colonies than similar plates not exposed, the matter was too complicated to give satisfactory results. Obviously one objection was that the spores might have begun to germinate, and the young colonies killed by the high temperatures

Experiments made in October with gelatine plates wrapped in black paper, in which a figure—a square, cross, or letter—was cut, also led to results too indefinite for satisfaction, although it was clear in some cases that if the plates lay quite flat, the illuminated area was on the whole clear of colonies, while that part of the plate covered by the paper was full of colonies

But another source of vexation arose. After the plates had been exposed to the sunlight for, say, six hours, it was necessary to put them in the incubator (20°-22° C was the temperature used) for two days or so, to develop the colonies, and in many cases it was observed that by the time the colonies were sufficiently

[1] See p. 237 of "First Report to the Water Research Committee of the Royal Society" ("Roy Soc Proc." vol 51, 1892) for the literature on this subject up to 1891

[2] It appears that Buchner (*Centr f, bakt* vol xii 1892) has already done this for typhoid, and finds the direct rays of the summer sun quite effective.

far advanced to show up clearly, liquefaction had extended so far as to render the figure blurred and doubtful

Stencil plates of zinc were employed with, at first, equally uncertain results The stencil plate was fixed to the bottom of the plate culture, outside, and every other part covered with blackened paper the plate was then placed on a level surface, the stencil-covered face upward, and exposed to the direct sunlight. As before, the gelatine softened and in many cases ran, and the results were uncertain, though not altogether discouraging

In November it was found that more definite results could be obtained, and the problem was at last solved

Meanwhile it had already been found possible to obtain sun prints in the following way with agar plates Ordinary agar was heated and allowed to cool to between 50° and 60° C, and was then richly infected with anthrax spores, and made into plates as usual Such plates were then covered with a stencil plate on the lower face—the stencil plate being therefore separated from the infected agar only by the glass of the plate—and wrapped elsewhere closely in dull black paper, so that, on exposure to the sun only the cut-out figure or letter allowed the solar rays to reach the agar

Such plates were then exposed to the direct rays of the October sun for from two to six hours, or they were placed on the

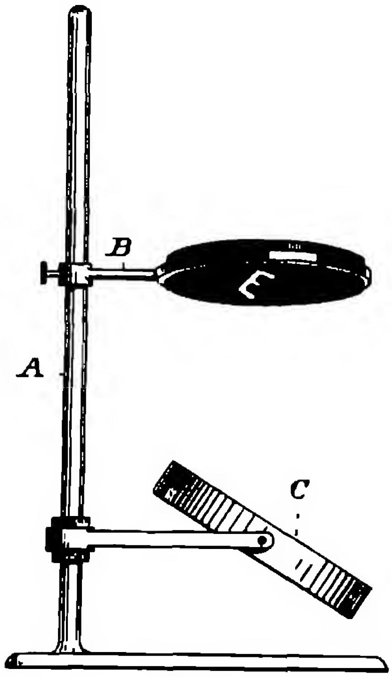

FIG 1

ring of a retort stand, stencil downwards, and the sunlight reflected upwards from a plane mirror below

After the insolation these plates were incubated for at least forty-eight hours at 20° C, and on removing the wrappers the colonies of anthrax were found densely covering all parts of the plate except the area—a letter or cross, &c—exposed to the sunlight. There, however, the spores were killed, and the agar remained perfectly clear, showing the form of a sharp transparent letter, cross, &c., in a groundwork rendered cloudy and opaque by the innumerable colonies of anthrax.

Experiments proved that this was not due to high temperature, for a thermometer with its bulb next the insolated glass rarely rose beyond 14° to 16° C, and never beyond 18° C., and even if the thermometer did not record the temperature inside the plate, this can scarcely have been much higher.

As long as this latter point remained uncertain, however, the experiments could not be regarded as satisfactory; whence it was necessary to again have recourse to gelatine cultures. The gelatine employed began to run at 29° C, and in November it was found that such plates exposed outside, either to directly incident sunshine, or to directly reflected rays, showed a temperature of 12° to 13° C at the insolated glass surface, and even five to six hours exposure caused no running of the gelatine

The following experiment may be selected as a type of the rest —A (Fig. 1) is the upright of an ordinary retort-stand, on the ring B rested a gelatine plate culture of anthrax spores, covered with black paper everywhere except the cut out letter E, seen on its lower face C was an ordinary plane microscope mirror with its arm fitted to a cork on A

The whole was placed in the middle of a field at 9 30 a m on Wednesday, November 30, and exposed to the clear, but low, sunshine which prevailed that day, the mirror being so arranged (from time to time as necessary) as to reflect the light on the E the whole period, until 3 30 p m, when the plate was removed and placed in the dark incubator at 20° C On the following Friday—i e after less than forty-eight hours' incubation—the letter E stood out sharp and clearly transparent from the faint grey of the rest of the plate of gelatine Not a trace of anthrax could be found in the clear area, even with the microscope, while the grey and almost opaque appearance of the rest of the plate was due to innumerable colonies of that organism which had developed in the interval

It was impossible to incubate the plate longer for fear of liquefaction, whence the sceptical may reply that the anthrax exposed to light was only retarded, the experiments with agar show that such is not the case, however, and that if the insolation is com-

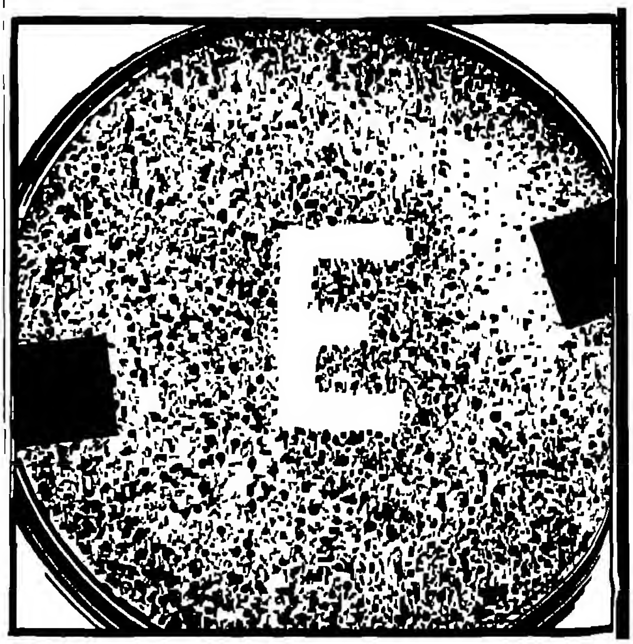

FIG 2

plete the spores are rendered incapable of germinating at all, as proved by removing pieces of the clear agar or gelatine and attempting to make tube cultures from them in all cases where insolation is complete they remain sterile

The chief value of these gelatine plate exposures in November, however, is that they prove conclusively (1) that the rays of a *winter* sun are capable, even if reflected, of killing the spores, and (2) that it is really the solar rays which do this directly, and not any effect of a higher temperature, since the gelatine remains solid throughout

Experience has shown, however, that some precautions are necessary in selecting the anthrax cultures employed for these experiments with gelatine The light certainly retards or kills (according to its intensity or the length of exposure) virulent spores, but if one takes the spores, mixed with vegetative bacilli, direct from a thoroughly liquefied gelatine culture, or from a bouillon culture, the plates are apt to be liquefied too rapidly for the proper development of the light print, evidently because so much of the liquefying enzyme is carried in when inoculating the plates The same danger is run when active bacilli alone are employed

The best method of avoiding these disadvantages has been

found to be the following, and it has the additional merit of enabling us to prove, beyond all doubt, that the ripe spores of *Bacillus anthracis* are really inhibited or killed by sunlight.

A few c c of sterile distilled water in a tube are thoroughly saturated with the anthrax spores taken from an old culture which has never been exposed to light, and the tube placed for twenty four hours at 56° C, this kills all immature spores, bacilli, and enzymes, and leaves us with a crop of the most resistant and fully matured virulent spores

Experiments with such spores have been made to determine the relative power of the different rays of the spectrum to destroy the anthrax.

It is necessary to note first, however, that in experimenting with the electric light, although but few exposures have been made as yet, it is evident that its effects are feebler than those of the winter sun

At present it has only been possible to observe that the inhibiting effects are stronger at the blue end of the spectrum than at the red, and exposures to sunlight passing through coloured glasses confirm this result, but the observations are being continued in the hope of getting a perfectly sharp record of the effects of each set of rays

The following series of experiments are quoted in detail, because they teach several details of importance, in addition to proving the main fact

On December 7 three gelatine plates and five agar plates were prepared with spores from a very vigorous and virulent agar tube of anthrax. The spores, which were quite mature, were not subjected to heat, but simply shaken in sterile water to wash and separate them thoroughly

The three gelatine plates were made at 35° C, the agar plates at 60° C, neither of which temperatures could injure the ripe spores.

The three gelatine plates were labelled *p* 1, *p* 2, and *p* 3, and the agar plates *p* 4 to *p* 8 in order

Immediately after making the plates, all were exposed to the December sun, except plates *p* 4, *p* 5, and *p* 6, and this was done as follows —In each case the plate had a stencil plate with a cut out letter on its lower face, and arranged as described above

p 1, a gelatine plate with a *large* letter M, was exposed, face down, to the light reflected from a mirror (see Fig 1) for three hours on December 7, and for four hours on December 8, the interval being passed in a cold room (*t* about 8°-9° C), and then incubated at 20° in the dark

p 8 was treated in exactly the same manner But this was an agar plate with a *large* W

p 2, a gelatine plate with a *large* H, was exposed and heated in the same way, except that no mirror was used, the latter being upwards towards the sun

p 3, a gelatine plate with a *large* B, was similarly exposed, face up, but a plane mirror arranged to reflect light down upon it

p 7, an agar plate with a *large* E, was treated exactly as the last

There now remain the three agar plates, *p* 4, *p* 5, and *p* 6, to account for

p 4 was placed forthwith in the dark incubator at 20° C

p 5 and *p* 6 were kept for eighteen hours in a drawer, the average temperature of which is almost 16° C, and were not exposed till next day (December 8), when they lay for five hours, face upwards, and with a mirror above them *p* 5 had a *small* E, and *p* 6 a broad but small I to let the light in

After exposure, these also were put in the same incubator with the others

Nothing was visible to the unaided eye on these plates (except *p* 4) until the 11th instant, though the microscope showed that germination was proceeding on the 10th The plate *p* 4, however, had a distinct veil of colonies all over it on the 9th, and this had developed to a dense typical growth by the 11th.

On December 11, at 10 a.m., the state of affairs, as regards the exposed plates, was as follows —

p 5 and *p* 6 showed each a sharp transparent letter—E and I respectively—of clear agar in a dull grey matrix of strong anthrax colonies, which covered all the unexposed parts of the plate

p 1, *p* 2, and *p* 3 showed in each case a perfectly clear central patch, about 1½ inches diameter, with anthrax colonies in the gelatine around These anthrax colonies were the *larger and more vigorous the more distant they were from the clear centre* In other words, the anthrax spores had begun to germinate, and the colonies were growing more vigorously, in centripetal order

On *p* 7 and *p* 8 germination was beginning, but the colonies were as yet too young to enable one to judge of the results

The first point of interest is to account for the pronounced results in the plates *p* 5 and *p* 6, and the want of sharp outlines in *p* 1, *p* 2, and *p* 3, and the explanation seems to be that, owing to the plates 5 and 6 having laid over night at 16° C, the spores began slowly to germinate out, *and were consequently in their most tender condition* when exposed to the sunlight next day

The peculiar centripetal order of development of the colonies on plates *p* 1, *p* 2, and *p* 3 gave rise to the following attempt at explanation After observing that the clear space in the middle was not due to the centre of the plate being raised, and the infected gelatine having run down to the periphery—a possible event with some batches of Petrie's dishes—it was surmised that the *large* letters employed might give the clue

This was found to be the case The solar rays on entering the plate were largely reflected from the glass lid of the plates, and so produced feebler insolation effects on parts of the plate around the letter, these effects were naturally feebler and feebler towards the margin, and so the inhibitory action became less pronounced at distances further and further removed from the centre Those spores, therefore, which were nearest the periphery germinated out first, and those nearer the centre were retarded and more and more in proportion to their proximity to the insolated letter

That this is the correct interpretation of the facts follows clearly from the further behaviour of the above plates

At 10 p m on the 11th—*i e* twelve hours after the morning examination—the plates *p* 1, *p* 2, and *p* 3 exhibited their respective letters M, H, and B quite clearly, in the grey matrix of anthrax which had rapidly developed in the interval, and excepting a slight want of sharpness in the H of *p* 2, the results could hardly have been more satisfactory

In *p* 7 and *p* 8 the *very faint* outlines of the letters were also showing

On the 12th, at 8 30 a.m, the gelatine plates had begun to run, and although the M of *p* 1 was still intact, and very well marked, *p* 2 had liquefied completely, so that the H was a clear patch with blurred outlines in the centre. *p* 3 still showed the outlines of the B, but it was impossible to keep it longer

The main point was definitely established, however, and the treatment of the plates proves conclusively that the spores are not killed by high or low temperatures, *but by the direct solar rays*

These experiments are being continued in order to answer some other questions in this connection

The gelatine and agar after such exposures as have been described are still capable of supporting a growth of *B anthracis* if fresh spores are sown on them, whence the effects described are not merely due to the sub-strata being spoilt as food material

Royal Meteorological Society, January 18 —Dr C. Theodore Williams, President, in the chair —After the report had been read, and the officers and council for the ensuing year had been elected, the President delivered an address on the high altitudes of Colorado and their climates, which was illustrated by a number of lantern slides.—Dr Williams first noticed the geography of the plateaux of these regions, culminating step by step in the heights of the rocky mountains, and described the lofty peaks, the great parks, the rugged and grand cañons, and the rolling prairie, dividing them into four classes of elevations between 5000 and 14,500 feet above sea level He then dwelt on the meteorology of each of these divisions, giving the rainfall and relative humidity, and accounting for its very small percentage by the moisture being condensed on the mountain ranges of the Sierras lying to the west of the Rockies, also noticing the amount of sunshine and of cloudless weather, the maxima and minima temperatures, the wind force, and the barometric pressure Dr Williams quoted some striking examples of electrical phenomena witnessed on Pike's Peak (14,147 feet) by the observer of the U.S Weather Bureau, when during a violent thunderstorm flashes of fire and loud reports, with heavy showers of sleet, surrounded the summit in all directions, and brilliant jets of flame of a rose-white colour jumped from point to point on the electric wire, while the cups of the anemometer, which were revolving rapidly, appeared as one solid ring of fire, from which issued a loud rushing and hissing sound. During another storm the

observer was lifted off his feet by the electric fluid, while the wristband of his woollen shirt, as soon as it became damp, formed a fiery ring around his arm. The climate of the Parks is, however, Dr. Williams considered, of more practical interest, and in these magnificent basins of park like country interspersed with pines, and backed by gigantic mountains, are resorts replete with interest for the artist, the sportsman, the man of science, and the seeker for health. Most of them lie at heights of from 7000 to 9000 feet, and so good is the shelter that usually snow does not long remain on the ground, while Herefordshire cattle in excellent condition are able to fatten on the good herbage, and to lie out all the winter without shed or stable. Dr. Williams predicted for these parks a great future as high altitude sanitaria for the American continent, especially as several of them have been brought within easy distance of Denver, the queen city of the plains, by various lines of railway. The resorts on the foothills and on the prairie plains, at elevations of 5000 to 7000 feet, include, besides Denver, Colorado Springs, Manitou, Boulder, Golden, and other health stations, which can be inhabited all the year round, and where most of the comforts and luxuries of American civilisation are attainable in a climate where not more than half a day a week in winter is clouded over, where the rainfall is only about 14 inches annually, most of which falls during summer thunderstorms, where the sun shines brightly for 330 days each year, and where the air is so transparent that objects twenty miles off appear close at hand, and high peaks are calculated to be visible at a distance of 120 miles. Dr. Williams summed up thus:—The chief features of the climate of Colorado appear to be (1) Diminished barometric pressure, owing to altitude, which, throughout the greater part of the State, does not fall below 5000 feet. (2) Great atmospheric dryness, especially in winter and autumn, as shown by the small rainfall and low percentage of relative humidity. (3) Clearness of atmosphere and absence of fog or cloud. (4) Abundant sunshine all the year round, but especially in winter and autumn. (5) Marked diathermancy of atmosphere, producing an increase in the difference of sun and shade temperatures, varying with the elevation in the proportion of 1° for every rise of 235 feet. (6) Considerable air movement, even in the middle of summer, which promotes evaporation and tempers the solar heat. (7) The presence of a large amount of atmospheric electricity. Thus the climate of this state is dry and sunny, with bracing and energising qualities, permitting outdoor exercise all the year round, the favourable results of which may be seen in the large number of former consumptives whom it has rescued from the life of invalidism and converted into healthy active workers; and its stimulating and exhilarating influence may also be traced in the wonderful enterprise and unceasing labour which the Colorado people have shown in developing the riches, agricultural and mineral, of their country.

Entomological Society, January 18.—Sixtieth Annual Meeting.—Mr. Frederick DuCane Godman, F.R.S., President, in the chair.—An abstract of the treasurer's accounts having been read by Mr. J. Jenner Weir, one of the auditors, the secretary, Mr. H. Goss, read the report of the Council. After the ballot it was announced that the following gentlemen had been elected as officers and Council for 1893:—President, Mr. Henry J. Elwes; Treasurer, Mr. R. McLachlan, F.R.S.; Secretaries, Mr. Herbert Goss and the Rev. Canon Fowler; Librarian, Mr. George C. Champion; and as other members of the Council, Mr. C. G. Barrett, Mr. Charles J. Gahan, Mr. F. DuCane Godman, F.R.S., Mr. Frederic Merrifield, Mr. Osbert Salvin, F.R.S., Dr. David Sharp, F.R.S., Colonel Charles Swinhoe, and Mr. George H. Verrall. The President then delivered an address which, though containing reference to the Society's internal affairs and an allusion to the successful resistance made by naturalists and others to the War Office scheme for establishing a rifle range in the New Forest, consisted for the most part of full obituary notices of Fellows of the Society who had died during the year, special mention being made of Mr. Henry W. Bates, F.R.S., Prof. Hermann C. C. Burmeister, Dr. Carl A. Dohrn, Mr. H. Berkeley James, Mr. J. T. Harris, Sir Richard Owen, K.C.B., F.R.S., Mr. Henry T. Stainton, F.R.S., Mr. Howard Vaughan, and Prof. J. O. Westwood, the Hon. Life President. Votes of thanks to the President and other officers of the Society having been proposed by Lord Walsingham, F.R.S., and Dr. D. Sharp, F.R.S., and seconded by Mr. J. H. Leech and Mr. W. H. B. Fletcher, Mr. Godman, Mr. McLachlan, Mr. H. Goss, and Canon Fowler severally replied, and the proceedings terminated.

Linnean Society, January 19.—General Meeting, Prof. Charles Stewart, President, in the chair.—After the confirmation of the minutes the President referred in suitable terms to the losses sustained by biologic science in the deaths of Sir Richard Owen and Prof. J. O. Westwood, who had been Fellows of the Society for 56 and 64 years respectively.—Mr. George Brook showed photographs of corals which he had lately taken and had reproduced by permanent process at a cost below lithography, with the added advantage of permitting amplification by a hand lens.—The President read a paper on the auditory organ of the angel fish (*Rhina squatina*).—Mr. W. Carruthers, F.R.S., V.P.L.S., then laid before the Society the results of a collection made by Mr. Alexander Whyte in the Malanji country, in the Shire highlands, in October, 1891, and the plants were determined by the officers of the Botanical Department, British Museum, about sixty, or, roughly speaking, one fifth, proving new to science. Whilst Sir J. D. Hooker defined the flora of Kilimanjaro as Abyssinian in character, the Malanji flora displays a much closer relationship to the Cape.—The last paper was by Mr. G. F. Scott Elliot, and was his report as botanist to the Anglo-French Sierra Leone Boundary Commission, in which he gave an account of the economic aspects of the districts traversed.

Geological Society, January 11.—W. H. Hudleston, F.R.S., President, in the chair.—The following communications were read:—Variolite of the Lleyn, and associated volcanic rocks, by Catherine A. Raisin, B.Sc. Communicated by Prof. T. G. Bonney, F.R.S. The district in which these rocks occur is the south-western part of the Lleyn peninsula, marked on the Geological Survey map as "metamorphosed Cambrian." Some of the holocrystalline rocks are probably later intrusions. The igneous rocks, which are described in detail in the present paper, belong to the class of rather basic andesites or not very basic basalts; they show two extreme types, which were probably formed by differentiation from an originally homogeneous magma. Corresponding to the two types of rock are two forms of variolite. These are fully described, and their mode of development is discussed. The variolites occur near Aberdaron, and at places along the coast. Their spherulitic structure often is developed towards the exterior of contraction-spheroids, and in this and in other particulars they correspond with those of the Fichtelgebirge and of the Durance. The volcanic rocks include lava-flows and fragmental masses, both fine ash and coarse agglomerate. They are associated with limestones, quartzose, and other rocks, which are possibly sedimentary, but which give no trustworthy evidence of the age of the variolites. Prof. Judd complimented the authoress on the evidently great amount of labour and patient research devoted to this investigation. He thought the occurrence of the spherulitic structure round the surfaces of "pillow like masses," similar to those described by Prof. Dana, was exceedingly interesting, especially when one considered the probably very great antiquity of these Caernarvonshire rocks. He thought, also, the suggestion that early crystallised magnetite grains had formed the nuclei of the spherulites, was a very interesting and probable one. Mr. Alfred Harker, Profs. Bonney, Hull, and J. F. Blake also spoke.—On the petrography of the island of Capraja, by Hamilton Emmons. Communicated by Sir Archibald Geikie, For. Sec. R.S. The rocks of Capraja consist generally of andesitic outflows resting on andesitic breccias and conglomerates. The southern end seems to have formed a distinct centre of volcanic activity, whose products are younger in age and more basic in character than the rocks of the rest of the island, and may be termed "anamesites." The lavas appear to have flowed from a vent at some distance from the cone, which probably occurred here, and gave out highly scoriaceous fragments. In the other parts of the island andesite is almost everywhere formed, with patches of the underlying breccias here and there in the valley bottoms. The chief centre of activity probably lay west of the centre of the island. Petrographical details of the andesites and anamesites, descriptions of the groundmass and included minerals of each, and chemical analyses are given. As regards the age of the constituents, the author arranges them in the following order, commencing with the oldest:—Magnetite, olivine, augite, mica, felspar, nepheline. After the reading of this paper Dr. Du Riche Preller gave an outline of the leading geological and the

analogous petrological features of the several islands of the Tuscan Archipelago, of Corsica, Sardinia, the Carrara mountains, and the Maremma hills The President also spoke

Zoological Society, January 17 —Sir W H Flower, F R S President, in the chair.—The Secretary read a report on the additions that had been made to the society's menagerie during the month of December, 1892 —Mr F. C Selous exhibited and made remarks on the head of a hybrid antelope between the Sassaby (*Bubalis lunata*) and Hartebeest (*B caama*), also a head of a female Koodoo (*Strepsiceros kudu*) with horns, and heads of some other South African antelopes —Mr O Thomas exhibited some examples (from the Baram River, Sarawak, collected by Mr Hose) of the monkey that he had lately described as *Semnopithecus cruciger*, and stated that, in spite of the confirmation afforded by these specimens, Mr. Hose thought that this species might possibly be only an erythrism of *S chrysomelas* —A communication was read from Mr E. Y Watson, entitled "A proposed classification of the *Hesperiidæ*, with a revision of the Genera." This contained a preliminary classification of the *Hesperiidæ*, including the numerous modern genera, which were arranged under three subfamilies according to the sexual differences, the resting posture, the antennæ, the spurs on the hind tibiæ, and the position of vein 5 (relative to veins 4 and 6) of the fore wing The subfamilies were named Pyrrhopyginæ, Hesperiinæ, and Pamphilinæ, and the two last were subdivided into sections without names In all 234 generic names were dealt with, of which 49 were treated as synonyms, while 45 new genera were described Complete diagnoses were given of all the admitted genera —A communication was read by Mr E E Austen, entitled "Descriptions of New Species of Dipterous Insects of the Family *Syrphidæ*, in the Collection of the British Museum, with Notes on Species described by the late Francis Walker" This communication contained descriptions of twenty-three new species belonging to the division *Bacchini*, and of one belonging to the *Brachyopini* (genus *Rhingia*) An attempt was made to divide the genus *Baccha*, as at present existing, into three groups, based chiefly upon the shape and markings of the abdomen The true position of the remarkable genus *Lycastrirhyncha*, founded by Bigot on a species from Brazil, and afterwards cancelled by its author in favour of *Rhingia*, was established It was shown that this genus had nothing to do with *Rhingia*, but was one of the *Eristalini*, closely allied to *Eristalis* It was also shown that the genus *Lycastris*, founded by Walker for a species from India, was not identical with *Rhingia* (as had been likewise suggested by Bigot), but belonged to the *Xylotini*, and was allied to *Criorrhina* A communication was read from Mr. Gilbert C Bourne, containing descriptions of two new species of Copepodous Crustaceans from Zanzibar, proposed to be called *Canthocamptus finni* and *Cyclops africanus* —Mr Sclater exhibited and made remarks on the typical specimen of a rare Argentine bird (*Xenopsaris albinucha*) described by the late Dr Burmeister in 1868

Anthropological Institute, January 24 —Anniversary meeting —Dr Edward B Tylor, F R S, in the chair —The following were elected officers and council for the ensuing year —President, Prof A Macalister Vice Presidents, J G Garson, Chas H. Read, F W Rudler Secretary, C Peek Treasurer, A. L Lewis Council G M. Atkinson, Henry Balfour, E W. Brabrooke, Hyde Clarke, J. F. Collingwood, Prof D J Cunningham, W L. Distant, J. Edge Partington, A J. Evans, H Gosselan, Prof A C Haddon, T V Holmes, R Biddulph Martin, R Munro, F G H Price, Oldfield Thomas, Arthur Thomson, Coutts Trotter, M J Walhouse, Gen. Sir C P Beauchamp Walker

EDINBURGH

Royal Society, January 16 —Prof Copeland, Vice-President, in the chair —A paper, by Dr W. Pole, on the present state of knowledge and opinion in regard to colour blindness, was communicated. He discussed alone the red-green form of colour blindness In such a case the solar spectrum presents only two hues separated by a nearly colourless portion—a mixture of blue and yellow light, giving rise to a gray colour According to Young the three primary colour sensations correspond to red, green, and blue or violet, and Maxwell and Helmholtz, reasoning on this theory, conclude that the colours seen in dichromic vision are green and blue. According to Dr Pole, they are yellow and blue. He asserts that comparisons between normal and abnormal visions show that in general matches of colours made by a normal eye are also matches when regarded by a dichromic eye He concludes that the two dichromic colours are colours known in normal vision He then gives reasons for the conclusion that these colours are normal blue and yellow In answer to the suggestion that the real subjective impressions may differ from what they are supposed to be, he says that the correspondence is proved by a large amount of evidence obtained by comparison with normal phenomena He thinks that the following conclusions may be drawn from the second edition of Helmholtz's work on optics —(1) The original mode of explanation of colour blindness by Young's theory is essentially withdrawn as no longer consistent with modern knowledge The universal concurrent testimony, that the ordinary colour dichromic vision generally corresponds with is normal yellow and blue and white, is no longer disputed, and although there are variations of sensations in regard to red and green, the old ideas of blindness to red and green as separate and contrasting defects are abandoned, (2) that Young's general theory of three fundamental colour sensations is still adhered to, but that the colours are now believed to differ considerably in the spectrum; (3) that dichromic vision might exist consistently with the retention of three fundamentals, (4) that the most prevalent form of dichromatism might be explained by the junction of the red and green fundamentals forming yellow In conclusion, he regretted that the colour vision committee of the Royal Society, in a recent chart dealing with colour blindness, had adhered to the old view held by Clerk Maxwell Sir George Stokes remarked that the fundamental part of Young's original theory was that there were three colour sensations, and though he supposed them to be red, green, and violet, that was not essential Maxwell only chose red, green, and blue, as representative sensations He was doubtful of the wisdom of publishing the charts alluded to lest it might lead to misconception The object of publishing them was to give to the public a general idea of the conclusions derivable from the trichromic theory

SYDNEY

Royal Society of New South Wales, December 7, 1892 —Prof Warren, President, in the chair —The Chairman announced that the Clarke Medal for 1893 had been awarded by the Council to Prof Ralph Tate, of the Adelaide University —A letter was read from the Hon Ralph Abercromby, enclosing a cheque for £100, which he desired to place in the hands of the Council of the Society with the object of bringing about an exhaustive study of certain features of the Australian weather, the particulars to be furnished in a later letter The following papers were read —Observations on shell heaps and shell beds, the significance and importance of the record they afford, by E J Statham —A new mineral from Broken Hill, by C W Marsh (communicated by Prof Liversidge) —Notes on some Australian stone weapons, by Prof Liversidge, F R S —Notes on the recent cholera epidemic in Germany, by Dr. Schwarzbach —Results of observations of Wolf's comet II., 1891, Swift's comet I, 1892, and Winnecke's periodical comet, 1892, at Windsor, New South Wales, by John Tebbutt —On the comet in the constellation Andromeda, by John Tebbutt —Languages of Oceania, by Dr John Fraser

August 17 —*Engineering Section* —C. W Darley in the chair —Papers read —Various systems of tramway traction, by W F How ——November 16 —Some notes on the economical use of steam, by T H. Houghton —Recent bridge building in New Zealand, by A Alabaster

PARIS

Academy of Sciences, January 23 —M Lœwy in the chair —Note on Nicolas de Kokcharow, by M Daubrée —Contributions to the study of the function of camphoric acid, by M A Haller —On the pepto-saccharifiant action of the blood and the organs, by M. R Lépine If blood is poured into several parts of water at 56° C a considerable quantity of sugar is formed in a few seconds, and the formation goes on for about an hour with decreasing rapidity. In cold or lukewarm water sugar is also produced, but its production is for the most part compensated by simultaneous glycolysis. It is also probable that the production of sugar is preceded by that of peptone If an organ which does not enclose glycogen in any perceptible quantity be macerated for about an hour in three or four parts of water, the aqueous extract only contains a very small quantity

of substances capable of reducing Fehling's solution, and hardly any sugar If to this aqueous extract be added a small quantity of peptone, and the whole be kept at 56°C during an hour, a certain quantity of sugar is formed, as proved by fermentation and the phenylhydrazine test Hence the aqueous or glycerine extract contains a ferment which may be termed pepto-saccharifiant It is probable that the formation of sugar is not confined to the liver, as ordinarily supposed, but that several organs play a part in it —Observations of the planet Charlois T (December 11, 1892), made at the Toulouse Observatory, by M B Baillaud —Contribution to the investigation of the solar corona apart from total eclipses, by M H Deslandres (see Astronomical Column) —Observations of the sun made at the Lyon Observatory (Brunner equatorial) during the latter half of 1892, by M Guillaume —On the limitation of degree for the general algebraic integral of the differential equation of the first order, by M Autonne —On Van der Waals's equation and the demonstration of the theorem of the corresponding states, by M G Meslin —Magnetic properties of bodies at different temperatures, by M P Curie —The magnetic permeabilities of a series of diamagnetic bodies, including, amongst others, bismuth, antimony, phosphorus, sulphur, and some potassium salts, were determined by enclosing them in an exhausted glass vessel exposed to a magnetic field, and subsequently repeating the experiment with the glass alone Most of the substances showed a remarkably constant coefficient Water and quartz did not show a perceptible variation with temperature, and potassium nitrate had the same coefficient when solid and when fused That of bismuth, on the other hand, fell steadily up to the point of fusion, and then (at 273° C) abruptly from 0 957 to 0 038, after which it remained constant Electrolytic antimony had a much feebler coefficient than the ordinary variety —Contribution to the study of equalisers of potential acting by flow, by M G Gouré de Villemontée —Luminous phenomena observed at the Lyon Observatory on the evening of January 6, 1893, by M Gonnessiat —A method for measuring objectively the spherical aberration of the living eye, by M C J A Leroy.—On the atomic weight of palladium, by MM. A Joly and E. Leidie —Action of the alkaline alcoholates on camphoric and other anhydrides, by M P Cazeneuve —Modification of arterial pressure under the influence of pyocyanic poisons, by MM Charrin and Teissier.—On some cases of infectious arthrodentary gingivitis observed in animals, by M V Galippe —Primary bedding of platinum in the Ural, by M. A Inostranzeff The native platinum occurs embedded in a rocky matrix consisting of the variety of peridotite known as dunite It is found in Mount Solovieff, which consists of alternate layers of chrome-iron and serpentine —On the existence of overfolds in the Blida Atlas (Algeria), by M. E Ficheur

BERLIN.

Physical Society, January 6 —Prof du Bois Reymond, President, in the chair —Prof. Raoul Pictet gave an account of experiments made by Messrs. Sarasin and De la Rive by which the rate of the electric waves discovered by Hertz had been measured, and their identity with waves of light in the ether determined By using large metallic surfaces sixteen metres in diameter as reflectors, and by allowing the discharge of the primary spark to take place under oil instead of in the air, it was found possible to obtain stationary electric waves in a long gallery and to determine their nodal points. In the discussion which ensued Prof Kundt stated that Dr Zenker was the first person who had explained the photographing of colours by means of stationary waves; that stationary light-waves were first experimentally determined by Dr Wiener, and that Seebeck was the first to take photographs of coloured objects. After Prof H W Vogel, pictures due to the action of li ht were first taken by a doctor named Schulz, in Halle. In 1727 this observer treated a solution of nitrate of silver in a small box with calcium chloride and obtained a greyish precipitate He then covered the box with a lid in which was a hole the shape of some letter, and on subsequently examining the precipitate he saw a dark image of the letter on it. The experiment was found to fail in the dark Schulz hence concluded that the image of the letter was due to the action of light.

Meteorological Society, January 10.—Prof Schwalbe, President, in the chair —Dr Kremser spoke on the imperfection of the means available for the study of atmospheric currents, which, even in the most elevated stations, are profoundly modified by the topography of the neighbourhood The direction and rate of these currents can only be ascertained by observing the motion of a small pilot-balloon of some one cubic metre capacity, a specially constructed theodolite being used for this purpose —Prof Hellmann exhibited a series of photographs of snow crystals taken by Dr Neuhauss, together with the oldest existing figures of these crystals, due to Olaus Magnus in 1455 The chief points of interest shown by these photographs were the not infrequent asymmetry of the crystals and the occurrence on them of small ice lumps

Physiological Society, January 13 —Prof du Bois Reymond, President, in the chair Dr Behring gave an account of the present state of affairs as regards what may be called the blood-serum therapeutists, illustrating his remarks by experiments he had made with serum from an immune horse on mice inoculated with tetanus bacilli A number of mice were inoculated with more or less strong doses of the bacilli Those which had previously been treated with the horse serum did not die, and in many cases where the serum was injected after the inoculation death did not ensue Observations on man are in progress, and will be published as soon as sufficient data are to hand on the treatment of tetanus and diphtheria by the use of serum from immune animals —Dr Hahn, of St Petersburg, gave an account of experiments made in conjunction with Profs Pawlow and Nencki on the action of an Eck's fistula, and the conducting of blood from the portal vein directly into the inferior vena cava Among the various results of the operation he stated that the output of urea was lessened and that of uric acid increased, a result which the experimenters attributed to a cessation in the conversion of carbamic acid into urea due to exclusion of the liver They further found that carbamic acid produced symptoms similar to those exhibited by the animals on which they had operated —Prof Kossel and Dr Raps exhibited an automatic mercurial pump for blood gas analysis

THE MILKY WAY

The Milky Way from the North Pole to 10° of South Declination, drawn at the Earl of Rosse's Observatory at Birr Castle By Otto Boeddicker (London Longmans, Green, and Co, 1892)

DR OTTO BOEDDICKER devoted the clear moonless nights for five years, from October 1884 to October 1889, to delineating the Milky Way as it appeared to his unaided eyes at Parsonstown, Ireland His drawings were deposited in the library of the Royal Astronomical Society, and a note accompanying them was read at the meeting of the Society in November 1889 The work now before us consists of four excellent lithographic reproductions of these drawings, a brief introductory preface being added by Dr Boeddicker

The working maps for the drawings were taken from Argelander's "Uranometria Nova," the Milky Way being inserted by means of stump and lead pencil This medium was found very unsuitable for photographic reproduction, and in preparing the lithographic stones for these charts photography was used for the stars, and the Milky Way was introduced by hand work. Mr W H Wesley, the Assistant Secretary of the Royal Astronomical Society, is responsible for this latter portion of the work, and the results are a splendid testimony to his care and skill Dr Boeddicker is to be congratulated upon having secured the services of so excellent an artist

Plate I is a detailed drawing of the Section Cygnus-Scutum, Plate II of the Section Cassiopeiæ, and Plate III of the Section Aurigæ-Gemini-Monocerotis In these plates an attempt has been made to represent accurately the appearance of the galaxy, all the differences of luminosity being represented as they actually appeared to Dr Boeddicker In Plate IV a general view on a smaller scale of the whole Milky Way from the North Pole to 10° south declination is given, the contrast being deliberately exaggerated in order to bring out clearly all the details

The area of the Milky Way indicated on these drawings is very much greater than that on any previously published representations, while for delicate details and faithful reproduction of contrast the plates are unapproached. In many respects Dr Boeddicker's drawings are a new revelation, branches, wisps, and feelers being shown extending from the main body so as to include stars, clusters and nebulæ, and even whole constellations not previously recognized as connected with or forming part of the Milky Way Polaris, γ Arietis, Prœsepe, the Pleiades, the Hyades, the great nebula in Andromeda, and nearly the whole of the constellation Orion, are thus joined to the galactic circle Numerous bright patches, channels, rifts, and interlacing lines of luminous matter hitherto unsuspected are revealed by Dr Boeddicker's long and patient work, and exponents of disc, spiral, and other theories as to the construction of the Milky Way will find considerable difficulty in accounting for the details shown.

It is very difficult to compare drawings of the Milky Way made by different observers without optical aid There are such wide variations in unaided vision, so many peculiarities introduced by long and short sight, by astigmatism, by irradiation in the retina, and by other physical and physiological imperfections, that it may safely be asserted that no two persons get exactly the same naked eye impression of such a vague object as the Milky Way As no details are given about Dr Boeddicker's eyes we are probably justified in inferring that they are practically normal, but we doubt whether any other observer, even with special training, could check or correct these charts with reasonable prospect of convincing the original artist of error in the representation of the Milky Way as it appeared to him Individual peculiarities of sight are minimized by the use of slight optical aid, and two equally experienced observers would be more likely to agree in their delineations of the Milky Way if they used similar telescopes, of say 1-inch aperture, or even ordinary opera glasses Dr Boeddicker's appeal to other observers to "verify and correct" his work will probably bring him plenty of correspondence, but can scarcely lead to any important correction in his magnificent drawings

Dr. Boeddicker considers that "the first step necessary towards the knowledge of the sidereal universe is a thorough acquaintance with the Milky Way as it appears to the naked eye," and hopes that by comparison and the superposition of naked-eye drawings on photographs "some knowledge of the structure of the Milky Way *in the line of sight* may be obtained" This idea is founded on the theory that there is a direct connection between the magnitudes of stars and their distances Littrow's analysis of Argelander's catalogue of stars certainly seemed to justify belief in this connection, but recent work has entirely disproved the hypothesis Measurements of the parallax of stars indubitably prove that some faint stars are near, while some of the brightest are at such distances as to have no appreciable parallax Thus α Orionis, α Virginis, α Leonis, and α Cygni have no parallax, while the 5th magnitude star 61 Cygni has a parallax of between 0″4 and 0″5 Photographs of the Pleiades show that we have in that cluster stars differing by as much as 13 magnitudes at approximately the same distance from us Russell's photograph of κ Crucis plainly indicates a direct physical connection between that star and many stars of the 14th and 15th magnitudes which should, according to the theory, be nearly 1000 times more distant. Streaks of nebulæ connect α Cygni and γ Cygni with long lines and stars of about the 16th magnitude in Dr. Max Wolf's photographs of the Milky Way From considerations of parallax observations of stars and from examination of photographs we are forced to conclude that there is no real connection between magnitude and distance, and that the differences of magnitude of stars are due to differences of size and physical condition. Stars differ enormously in light-giving power, and the actual light emitted by α Cygni must be nearly a million times greater than that from the faint stars directly connected with it and at practically the same distance from us. There is therefore very little chance of adding to our knowledge of the Milky Way "in the line of sight" by superposition of naked-eye drawings on photographs.

In his preface Dr. Boeddicker frequently speaks of

"nebulosity," "nebulous light," and "nebulous matter," when he means luminosity and luminous matter In ante spectroscopic days the terms nebula and cluster were used almost indiscriminately, a nebula being looked upon as simply an irresolvable cluster, and this error still survives in many astronomical text-books and compilations, but Dr Boeddicker should have avoided it. When we consider that the majority of the stars in the cluster which we call the Milky Way are of the Sirian type, we see how misleading is the use of the terms nebulous light and nebulous matter A T

THE THEORY OF SUBSTITUTIONS AND ITS APPLICATIONS TO ALGEBRA

The Theory of Substitutions and its Applications to Algebra By Dr Eugen Netto Translated by F N. Cole, Ph.D (Mich Ann Arbor, 1892)

THE theory of substitutions abstractly considered is concerned with the enumeration and classification of the permutations of a set of n different letters $x_1, x_2, \ldots, x_n$ It is scarcely apparent at first sight that a far-reaching mathematical theory could be built on a basis so simple, still less that there should be any connection between this and the complicated question of the solution of algebraical equations by means of radicals It may be worth while, in order to excite the interest of mathematical readers in the work before us, to mention one or two points in the Theory of Substitutions which will give an inkling of the nature of its connection with the interesting problem just mentioned.

The operation of replacing—say in any function $\phi(x_1, x_2, x_3)$—any permutation of the letters, say x_1, x_2, x_3, by any other, say x_1, x_3, x_2, is called a *substitution*. This operation is denoted explicitly by $\begin{pmatrix} x_1, x_2, x_3 \\ x_1, x_3, x_2 \end{pmatrix}$, or shortly by a single letter s. Thus $s\phi(x_1, x_2, x_3) = \phi(x_1, x_3, x_2)$, and again If t denote the substitution $\begin{pmatrix} x_1, x_2, x_3 \\ x_3, x_2, x_1 \end{pmatrix}$, $t\phi(x_1, x_3, x_2) = \phi(x_3, x_1, x_2)$ We may indicate the successive application of the two substitutions s and t by multiplying the symbols st in the order of application thus $st\phi(x_1, x_2, x_3) = \phi(x_3, x_1, x_2)$ and $ts\phi(x_1, x_2, x_3) = \phi(x_2, x_3, x_1)$ In particular, the repetition of the same substitution may be represented by powers of the symbol, thus $s^2\phi(x_1, x_2, x_3) = \phi(x_1, x_2, x_3)$. The identical substitution $\begin{pmatrix} x_1, x_2, x_3 \\ x_1, x_2, x_3 \end{pmatrix}$ is represented by unity. The total number of different substitutions of n letters is obviously $n!$, consequently, if we form the consecutive powers of any substitution we shall ultimately arrive at a power s^m which will be the identical substitution, m being some positive integer not exceeding $n!$ m is called the *order* and n the degree of the substitution

If among the substitutions of any given degree we can select a set which have the property that the product of any two furnishes another substitution belonging to the set, we obtain what is called a *group of substitutions*. The whole of the $n!$ substitutions of n letters obviously form a group, and the identical substitution by itself forms a group. It is easy, however, to see that in general there are other groups among the substitutions of a given degree Consider, for example, any rational function $\phi(x_1, x_2, \ldots, x_n)$ which is not wholly asymmetric: there must exist a set of substitutions each of which leaves the value of ϕ unaltered A substitution which is the product of any number of these must also leave ϕ unaltered: hence the set in question forms a group. We have here a fundamental point in the theory of substitutions, viz, the existence of a group of substitutions and the correlation therewith of rational functions which are unaltered by all the substitutions of the group The group is said to belong to all the functions which it leaves unaltered, and these functions are said to form a family which is characterized by the group. Thus the group of a wholly asymmetric function is the identical group consisting of the substitution [1], the group of the wholly symmetric functions consists of the whole of the $n!$ substitutions of the n^{th} degree, the group of the alternating functions consists of all those substitutions which are equivalent to an even number of transpositions, and so on It is obvious that every rational function determines a group of substitutions, and it may be shown that, conversely, for every group of substitutions we may construct an infinity of rational functions which are unaltered by the substitutions of the group The significance of this correlation between a group and a family of functions depends on the following important theorem, which is due in substance to Lagrange If ψ be a rational function which is unaltered by all the substitutions of the group of ϕ (in other words, if the group of ψ contain the group of ϕ) then ψ can be expressed as a rational function of ϕ, and the n elementary symmetric functions

$$C_1 = \Sigma x_1, C_2 = \Sigma x_1 x_2, \ldots, C_n = x_1 x_2 \ldots x_n$$

A particular case of this is the theorem that if the groups of ψ and ϕ be identical, then each can be expressed as a rational function of the other, and of the elementary symmetric functions A limiting case of this theorem is the familiar result that every rational symmetric function can be expressed as a rational function of the elementary symmetric functions As a special example consider the the two wholly asymmetric functions $\psi = ax_1 + bx_2$, $\phi = a/x_1 + b/x_2$ these both belong to the identical group, since they are changed by every substitution of the letters x_1, x_2. Hence ψ can be rationally expressed as a function of ϕ, C_1, C_2. The actual expression is in fact:

$$\psi = \{2(a-b)^2C_2 - (a^2+b^2)C_1^2 + (a+b)C_1C_2\phi\}\{-(a+b)C_1 + 2C_2\phi\}/(a-b)^2(C_1^2 - 4C_2).$$

The application of the theory of substitutions is limited in the first instance to rational functions Its use in the theory of the solution of algebraical equations by means of radicals is based on the following important result in the theory of irrational functions Any root of a solvable equation $f(x) = 0$ can be expressed as a rational integral function of certain elements $V_1, V_2, \ldots, V_1$, the coefficients of which are rational functions of the coefficients of $f(x)$ and of primitive roots of unity. The quantities $V_1, V_2, \ldots, V_n$ are on the one hand rational integral functions of the roots of $f(x) = 0$ and of primitive roots of unity, and on the other hand are determined by a series of equations:

$$V_a^{p_a} = F_a(V_{a-1}, V_{a-2}, \ldots, V_v),$$

where p_a is a prime number and F is a rational function of the V—s For example, in the case of the cubic

$x^3 - C_1x^2 + C_2x - C_3 = 0$, if $\Delta = -27C_3^2 + 18C_1C_2C_3 - 4C_1^3C_3 - 4C_2^3 + C_1^2C_2^2$, $S = 2C_1^3 - 9C_1C_2 + 27C_3$, $T = 9C_3 - 3C_1C_2$, the relations in question are

$$V_3^2 = -27\Delta,\ V_2^3 = \tfrac{1}{2}(S + V_3),\ V_1^3 = \tfrac{1}{2}(S - V_3),$$

$$V_1 = x_1 + \omega^2x_2 + \omega x_3,\ V_2 = x_1 + \omega x_2 + \omega^2x_3,$$

$$V_3 = T + 3\omega(x_1^2x_3 + x_2^2x_1 + x_3^2x_2) + 3\omega^2(x_1^2x_2 + x_2^2x_3 + x_3^2x_1);$$

$$x_1 = \tfrac{1}{3}\{C_1 + V_1 + V_2\},\ x_2 = \tfrac{1}{3}\{C_1 + \omega V_1 + \omega^2 V_2\},$$

$$x_3 = \tfrac{1}{3}\{C_1 + \omega^2 V_1 + \omega V_2\}$$

By means of this theorem and certain elementary principles of the theory of substitutions an elegant and simple demonstration can be given of Abel's theorem that the solution by radicals of the general equation of the n^{th} degree is impossible when $n > 4$ see § 217 of the work before us.

Although the theory of substitutions bears, as we have just shown, on some of the oldest and most interesting of the problems of algebra, it has been comparatively little studied, especially by English speaking mathematicians Dr Cole has therefore rendered us a service of great importance by translating one of the standard treatises on this subject Of the three that were at his disposal we think that he has chosen the one most likely to be useful to a beginner While Serret in his "Higher Algebra" and Jordan in his "Traité" treat the theory from an abstract and more general point of view, Dr Netto constantly associates with the substitution the function on which it is supposed to operate This gives a powerful concrete aid to the comprehension of the propositions of the abstract theory and also helps the student to grasp their application The great danger in subjects of such generality is that the stream of theorems is apt to run off the mind of the learner without soaking in, like water off the proverbial duck's back

Dr Netto's book will be found to contain all the ordinary theorems regarding the classification of substitutions, *e g* the existence of groups, transitive and intransitive, primitive and non primitive, simple and compound, the theory of the algebraic relations between the values of multiple-valued functions and between functions belonging to or included in the same family, and also a considerable number of theorems regarding special groups The applications embrace the theory of resolvents in general and of the Galois resolvent in particular, the general theory of the solvability of equations by means of radicals, the theory of the group of an equation and a discussion of the criteria of solvability, besides special applications to the cyclotomic and Abelian equations, and to equations three roots of which are connected by a rational relation

The translation has been admirably done, both from the lingulstic and from the mathematical point of view We found, it is true, here and there passages which were somewhat obscure, but in every case, on comparing with the original, we found the rendering to be absolutely faithful. Such obscurities therefore must be charged either to the author, or to the nature of the subject, or to the idiosyncrasy of the critic, and not to the translator We congratulate Mr. Cole on the successful completion of his arduous task, and heartily recommend the result to every lover of the most ancient and the most beautiful of all the sciences.

G CH

THE BRAIN IN MUDFISHES.

Das Centralnervensystem von Protopterus annectens, *eine vergleichend Anatomische Studie* Von Dr Rudolf Burckhardt. (Berlin R Friedlander und Sohn, 1892.)

THE Mudfishes, Dipnoi, from many peculiarities in their structure, have attracted the especial attention of anatomists and zoologists Important monographs on Lepidosiren have been written by Owen and Wiedersheim, whilst Huxley, Gunther, and Beauregard have described the anatomy of Ceratodus Serres, in 1863, made a contribution to the anatomy of the nervous system of Protopterus, Fulliquet in 1886, and Parker in 1888, have also added to our knowledge of its structure, and now Dr Burckhardt has published a well-illustrated monograph on the central nervous system of *Protopterus annectens* He had obtained an ample supply of this fish from Herr W Jezler, a merchant whose business engagements had taken him to the neighbourhood of Bathurst, Senegambia On more than one occasion Dr Burckhardt had received living fish, so that he was able to study the microscopic anatomy by the use of the most recent technical methods, and has thus added materially to our knowledge of the brain of this animal.

The author found, in the anterior horn of grey matter of the spinal cord, remarkably large nerve-cells, which possessed both branching protoplasm processes and an axial-cylinder process In the lateral and posterior horns nerve cells somewhat smaller in size were seen. The medulla oblongata gave origin to nerves which he names hypoglossal, vagus, glosso-pharyngeal, acusticofacialis, and trigeminus He also describes two slender nerves as abducens and trochlearis, so that the Dipnoi are not, as some have said, destitute of these nerves The cerebellum formed the anterior boundary of the 4th ventricle Large nerve-cells, corresponding to those of Purkinje in the mammalian brain, were not seen The mid-brain was distinct, and gave origin to a root of the trigeminus, to the optic tract and to the oculo-motor nerve grey matter containing nerve-cells was grouped around the aqueduct of Sylvius

Whilst Protopterus corresponded closely with the lowest vetebrates in the regions of the mid and hind brains it presented striking peculiarities in the pineal region The roof of the 3rd ventricle was complicated, and possessed a velum, which represented a middle choroid plexus; a conarium, and a structure like that which Edinger has named "Zirbelpolster" The epiphysis (*Zirbel*) was attached to the skull by the arachnoid membrane.

The fore brain was well developed, and divided into two hemispheres He recognized in it a posterior ventral swelling, which, because it contained cells similar to those found in the dentate gyrus (*fascia dentata*) of the higher brains, he describes as a lobus hippocampi He distinguished a fissure which separated the lobus olfactorius from the pallial part of the hemisphere, so that he harmonizes the fore brain in its fundamental divisions with the mammalian brain as described by Broca and Turner. He directs attention to an elevation ventrad of the lobus olfactorius, which he calls the lobus post-olfactorius. This lobe is also found in the brains of

Selachia and Amphibia, and apparently corresponds to the lobus olfactorius posterior described by His in the human embryo, which forms the anterior perforated spot in the adult human brain As regards its structure the hemisphere possessed central grey matter containing nerve-cells which lay around the hemisphere ventricle, also a mass of grey matter which he calls corpus striatum, whilst in the more posterior part of the ventral region of the hemisphere were nerve cells which represented a cortical layer. In the dorsal region of the hemisphere also cortical nerve-cells were found, which were arranged as an inner and an outer layer The cells of the cortex gave origin to nerve fibres A definite anterior commissure was present, the fibres of which passed on each side into the lobus hippocampi Burckhardt, also, figures, as distinct from the anterior commissure, fibres which he regards as the corpus callosum of Osborn The most important tract of nerve fibres was the basal bundle, which ascended from the spinal cord into the corpus striatum

One of the most interesting chapters in Burckhardt's memoir is that in which he gives an account of the saccus endolymphaticus Wiedersheim had described in 1876, in *Phyllodactylus europæus*, a sac with many branching diverticula, filled with otolith-sand and lying in relation to the choroid plexus of the 4th ventricle Hasse had previously seen in Amphibia a similar structure which Coggi had investigated in the frog Burckhardt has for the first time observed and figured it in Protopterus The saccus communicated by a narrow neck with the sacculus and utriculus of the auditory vesicle, and with its diverticula overlaid the region of the 4th ventricle, and extended as far back as the 1st pair of spinal nerves

The memoir contains a short chapter on the phyletic development of the brain of Protopterus Starting with Selachia, he considers that one line of development has been through Protopterus to Ichthyophis, and thence to the Urodela and Anura; another through Ceratodus to Reptilia and Mammalia, whilst a third line is from the Selachia to the Ganoids and Bony Fishes

OUR BOOK SHELF.

The Chemical Basis of the Animal Body. An Appendix to Foster's "Text-Book of Physiology" (fifth edition) By A Sheridan Lea, M A, D.Sc, F R S (London Macmillan and Co, 1892)

LIKE its parent volume, this well-known appendix has grown in bulk considerably, so that it now constitutes a treatise (separately paged and indexed) on the chemical substances occurring in the body. It contains numerous references to the text of Foster's "Physiology," and so the two may be most profitably read together.

The plan pursued in the present edition is the same as in former editions; the chemistry of the body is described under the headings of the names of the chemical substances. This plan has its advantages It for instance gives a completeness to the description of any particular substance, whereas the other plan of describing the facts of animal chemistry, under the headings of the tissues, organs, and functions involves a certain amount of repetition and the facts relating to any one group, such as the proteids and carbohydrates will be found distributed in different chapters Dr. Sheridan Lea's plan has, however, the disadvantage that it destroys continuity Many of the paragraphs are necessarily short, and one passes from one subject to another with a certain amount of abruptness The style of the writing is, however, interesting and clear, so that this disadvantage is reduced to a minimum The parts that treat the subject in a fuller style, such as those in which ferment action, the origin of urea in the economy, or the relation of hæmoglobin to bile pigment are discussed, are models of lucid writing

The book opens with a description of the proteids and ferments, the most important of physiological substances, but those of which, from the chemical standpoint, we know least The simpler materials found in the body or its excreta are treated next This is the more chemical part of the book, and the author expresses his indebtedness to Dr S Ruhemann for assistance here One doubts whether this part of the work will prove attractive to ordinary students There is no question that all medical students should be educated up to it, but at present organic chemistry and structural formulæ are subjects they are inclined to fight shy of The concluding chapters are again devoted to substances of which we have a physiological rather than a chemical knowledge, namely, the pigments.

The figures of crystals, which form a new feature in the present edition, have been taken from the works of Krukenberg, Kuhne, and Funke One cannot conclude this notice without alluding to the extensive references to literature that are given throughout This will prove a most valuable assistance to all original workers, and to those more earnest students who desire to go deeper into the subject The references are provided with a separate index. They are chiefly to German literature The German leanings of the author are seen also in the spelling of sarkosin, kreatin, &c The final *e* is always omitted in the names of the amido acids It would be a good thing in the future if international uniformity in the names of chemical compounds were adopted In the meantime it seems a pity that Dr Lea has not seen fit to use the spellings recommended by the Chemical Society of London

The author is to be congratulated on having brought his labours to a successful conclusion, and we can pay the present volume no better compliment than to say that it is well worthy of those that have preceded it

W D H

Chambers's Encyclopædia New Edition Vol X (London and Edinburgh W and R Chambers, 1892)

THE editor and publishers of the present work may be cordially congratulated on the fact that it has now been successfully completed A better encyclopædia of like scope does not exist in our own or any other language Nominally it is merely a new edition, but in reality, as the editor claims in the preface, it must be regarded as to all intents and purposes a new work One of the chief difficulties in an undertaking of this kind is to secure that each subject shall have the degree of attention which properly belongs to it, no single subject or group of subjects being permitted to usurp space which ought to be otherwise occupied. The editor has grappled with this difficulty so effectually that few readers will have occasion to complain of any lack of proportion in the length of the various articles Another striking merit of the work is that all important subjects have been entrusted to specialists, so that students may have full confidence in the accuracy of the information offered to them about matters in which they happen to be particularly interested. The space at the disposal of the writers was so limited that what they have to say is not, of course, exhaustive, but it is sound as far as it goes, and is generally presented with most praiseworthy simplicity and

clearness The present volume falls in no respect below the level of those which have preceded it Among the writers of scientific articles are Prof James Geikie, who deals with the triassic system and with volcanoes, Prof Knott, who expounds the principles of thermodynamics, Dr R W Philip, who writes of tubercle, and Sir F Bramwell, who has a paper on water-supply.

Arthur Young's Tour in Ireland (1776–79) Edited, with Introduction and Notes, by A W Hutton Two vols (London G Bell and Sons, 1892)

THIS reprint will be of real service to all who study the evolution of economic conditions in Ireland, and much of it ought also to excite and maintain the interest of the general reader Arthur Young, as every one knows, was a remarkably accurate observer of such things as travellers have opportunities of noting, and his book on Ireland is in its own way hardly less valuable than his more celebrated work on France The work was first published in 1780, in the course of which two English editions and one Irish edition were issued Since that time it has not until now been reprinted as a whole Mr Hutton has done his work as editor admirably, and a most useful bibliography has been prepared by Mr J P Anderson

LETTERS TO THE EDITOR

Some Lake Basins in France

A FEW weeks since M Delabecque, Ingénieur des Ponts et Chaussées at Thonon, kindly presented me with a copy of a work issued under his superintendence and to a great extent executed by himself,[1] to which I should be glad to call the attention of students of physiography M Delabecque, commissioned by the French Government, has made a series of soundings of ten lakes in France, near the Alpine region, and this Atlas records the results of his work Contour lines, in most cases 5 metres apart, indicate the forms of the lake basins, the use of varying tints in blue makes these more distinct Chief among the lakes included is the Léman, in the survey of which, as only one shore is French territory, the Swiss engineers have cooperated A copy of this on a reduced scale, and without colours, appeared in Prof Forel's book, "Le Lac Léman" (see NATURE, Nov 3, 1892) Next in importance come the lakes of Annecy and of Bourget, the remainder are situated either in the French Jura or on the margin of the outer limestone zone of the Alps, a little south of the Rhone

Excluding the Lake of Geneva, which was noticed in the article just mentioned, these lakes are especially interesting for their bearing on the difficult problem of the origin of lake-basins Except the Lac de Bourget, none of these can be said to lie in a great mountain valley, or on the probable track of a great glacier. If then their basins have been excavated by glaciers, we might fairly expect the Alps and Jura to be "spattered" with lakes, for no appeal can be made to exceptional circumstances while if the contours of their beds present resemblances to those of the larger Alpine lakes, such as the Lake of Geneva, the same explanation ought to apply in the main to both groups

Without a reproduction of the charts it is impossible to give more than a rough idea of the evidence which they afford, but the following statements may be helpful. As a general rule the lakes deepen as they broaden, the deepest water being commonly found in the widest part If in the course of the lake the shores markedly approach so as to form a kind of "narrow," this corresponds with a submerged neck or "col," which separates the bed into two basins, rising perhaps 10 metres or more above their general level Not seldom the bed of a lake consists of a linear series, three to six in number, of shallow basins, so that a contour line, drawn along the axis of the lake, undulates up and down with an "amplitude" of from perhaps 3 to 5 metres A rather long, blunt-ended oval is the prevalent form of these lakes, but to this there are exceptions So far as can be ascertained the contours of the land above the water line are reproduced beneath it For instance, under the steep slopes of the Mont du Chat the bed of the Lac de Bourget plunges abruptly down to a depth of over 120 m (its greatest depth being about 145 m)

Of the Jura lakes, the Lac de St Point (848 95 m above the sea) is rather more than 6 kilometres long, the general width being rather less than one-tenth of this, a considerable part of its floor is 30 to 35 metres deep, and its greatest depth is about 42 metres It contains no less than 6 basins, parted by "cols" about half-a-dozen metres above their lowest parts This lake is on the course of the Doubs, and lies parallel with the general strike of the Jura, *i e* from N E to S W The Lac de Brenets on the same river, nearly 100 metres lower down, is a narrow, winding lake, roughly 150 metres wide and perhaps 8 or 9 times as long At its upper end is a sharply projecting, rather shallow bay, but the channel of the Doubs can be traced clearly through this, deepening gradually from 5 to nearly 27 metres and the whole lake is evidently only an enlargement of the river

The subalpine lakes are no less interesting, and their testimony generally agrees with that summarised above Want of space forbids us to mention more than the lake of Annecy This is deepest (about 65 m) in its northern and widest part (nearest to the effluent) The sub-aqueous contours on the western side are interrupted, to within about 10 metres from the bottom of the lake, by a prominence, just like a drowned hilly spur The shallowest soundings over this, near its northern (outer) part, are only 3 3 metres, and the ground falls rapidly down from 5 to 55 metres On its northern or "lee" side (assuming a glacier to have followed the course of the water) is a submerged valley over 40 metres deep The Lake of Annecy exhibits another very singular feature Near its northern end the bed deepens very rapidly from 30 to 80 metres, this funnel shaped cavity is less than 200 metres in diameter, and is probably a submerged swallow hole These notes may, it is hoped, suffice to indicate the importance of this work The gratitude of students is due to M Delabecque for supplying them with a valuable group of facts, the collection of which must have entailed great labour These, however, appear to me not to lend themselves very readily to the support of the glacial excavation hypothesis, but to be more favourable to that which regards the larger Alpine lakes as mainly formed by movements of the earth's crust after the erosion of the valleys in which they lie T G BONNEY

[1] "Atlas des Lacs Français, Ministère des Travaux Publics." No publisher's name appears on the sheets, but I am informed by M Delabecque that the Atlas can be obtained at Georg's Library, Geneva.

Dust Photographs

IN Mr Croft's paper on "Breath Figures," printed in NATURE for December 22 of last year (pp 187, 188) he states — "Two cases have been reported to me where blinds with embossed letters have left a latent image on the window near which they lay" The statement is not quite clear as I do not understand whether the letters were in contact with the glass or not

Perhaps it may be interesting to place on record an observation of my own, made a few years ago, which struck me at the time as curious, but which I have not been able to verify since

At the stations of the District Railway there is a useful arrangement by which passengers are informed of the destination of the next train. It consists of a shallow box with glass sides into which by a mechanical contrivance boards are let down on which the names of the stations are painted in white letters on a blue ground The board with the words 'INNER CIRCLE' is most frequently exposed. At night the box is (or was) illuminated obliquely on either side by a tolerably powerful lamp

One night I was waiting for the train at the Victoria Station, There was some dislocation in the service, the destination of the next train was uncertain and the box was empty On glancing at it somewhat sideways I was however astonished to see the words 'INNER CIRCLE' on the glass side of the box in quite clear dark letters on a pale illuminated ground I drew the attention of one of the platform officials to it He saw it with perfect distinctness, and seemed to think he had

noticed it before Of course when the apparatus is in full working order there is little opportunity for doing so

The only explanation I could think of was —(i) that the light of the lamp had produced some molecular change in the paint coating the notice board ; (ii) that this had affected differently the blue and the white paint , (iii) that the same cause had set up some differential electrical condition of the board and the glass , (iv) that a bombardment of particles of the blue paint had taken place on to the glass to which they had adhered , and that (v) the particles so adhering, by dispersing the light, produced the effect of the pale illuminated ground while the spaces occupied by the letters being relatively clean stood out dark

MR W B CROFT'S paper on Breath-Figures in your issue of December 22 reminded me of some curious impressions of monumental brasses which are to be seen on the walls of Canterbury Cathedral When I saw these impressions a few years ago, it occurred to me that they might have been produced by mere contact, the brass plates having possibly been hung for many years against the walls, in secluded corners, at a time when the Reformers would not let them remain in their proper matrices on the church floor I had forgotten the particulars of these figures, but Dr Sheppard, of Canterbury, has kindly sent me the following notes by favour of Canon Fremantle —"A number of impressions of brasses are in the basement (which is open to the air) under Henry IV 's chantry in the Cathedral A very good impression is on the western column of the crypt of Trinity Chapel . . On the walls appear the shapes of the effigies Sometimes the stone is unstained all over the area of the figure, and surrounded by a broad dark smudge and sometimes the case is reversed, and the figure is the exact negative of the former kind , that is to say, the area of the figure is indicated by an uniform dark tint, whilst the surrounding stone is unstained " Dr Sheppard suggests "that an exact pattern seems to have been made in paper and then fixed to the wall whilst it was brushed over with linseed oil But this does not account for the white effigies on a dark ground "

I would commend these impressions to the notice of those interested in the subject It may be that, though some were made intentionally, others are the result of simple contact

Fossil Plants as Tests of Climate

IN continuation of my recent letter, permit me to call attention to a communication on the bread fruit trees in North America, by Mr F H Knowlton, of the National Museum, Washington, U S , which appears in your American contemporary *Science* for January 13 The forty living species of *Artocarpus* are all confined to tropical Asia and the Malay Archipelago *A incisa*, the true bread fruit tree, and one or two others, are largely cultivated in the tropics. They are small or medium-sized trees with a milky juice, large leathery leaves, and monœcious flowers The female flowers are long club-shaped spikes, which uniting form one large mass known as the "bread fruit," the interior containing a pulp when ripe like new bread

The first fossil bread fruit was discovered in boulder county Colorado in late cretaceous rock, and was named by the late Prof Leo Lesquereux *Myrica (?) Lessigiana*, other fragments he called *Aralia pungens* The subsequent researches, or more perfect specimens of Dr. A S Nathorst, proved these to belong to one species, *Artocarpus Lessigiana* Dr Nathorst is the discoverer of another species closely allied to *A. incisa*, which he calls *A Dicksoni*, which he obtained from the cretaceous flora of Waigatt, West Greenland, which the previous labours of Profs. Heer and Nordenskiold had shown to be of a tropical or sub tropical character, containing as it does numerous species of ferns of the order Gleicheniaceæ, and several species of cycas

CHAS E DE RANCE.

H.M Geological Survey, Alderley Edge, Manchester

Lunar Rainbow in the Highlands

THIS interesting phenomenon (a very unusual one in this latitude) was observed near here on the morning of the 3rd inst , about six a.m The moon was two days past full, and was not shining particularly brightly, being obscured, except at considerable intervals, by driving mist and light clouds. The bow, however, was exceedingly well marked, and formed a singularly beautiful object, stretching as it did completely across the north-western end of Loch Oich, glimmering against the dark background of the mountains, and sinking into the water on the southern shore of the loch The general colour of the bow was yellow deepening into orange, several of the prismatic colours, however, being intermittently visible, especially a tinge of violet on the upper side O S B

OPTICAL CONTINUITY[1]

KEENNESS of sight is measured by the angular distance apart of two dots when they can only just be distinguished as two, and do not become confused together It is usually reckoned that the normal eye is just able or just unable to distinguish points that lie one minute of a degree asunder. Now, one minute of a degree is the angle subtended by two points, separated by the 300th part of an inch, when they are viewed at the ordinary reading distance of one foot from the eye If, then, a row of fine dots touching one another, each as small as a bead of one 300th part of an inch in diameter, be arranged on the page of a book, they would appear to the ordinary reader to be an extremely fine and continuous line If the dots be replaced by short cross strokes, the line would look broader, but its apparent continuity would not be affected It is impossible to draw any line that shall commend itself to the eye as possessing more regularity than the image of a succession of dots or cross strokes, 300 to the inch, when viewed at the distance of a foot Every design, however delicate, that can be drawn with a line of uniform thickness by the best machine or the most consummate artist , admits of being mimicked by the coarsest chain, when it is viewed at such a distance that the angular length of each of its links shall not exceed one minute of a degree One of the apparently smoothest outlines in nature is that of the horizon of the sea during ordinary weather, although it is formed by waves The slopes of *débris* down the sides of distant mountains appear to sweep in beautifully smooth curves, but on reaching those mountains and climbing up the *débris*, the path may be exceedingly rough

The members of an audience sit at such various distances from the lecture table and screen, that it is not possible to illustrate as well as is desirable, the stages through which a row of dots appears to run into a continuous line, as the angular distance between the dots is lessened I have, however, hung up chains and rows of beads of various degrees of coarseness Some of these will appear as pure lines to all the audience , others, whose coarseness of structure is obvious to those who sit nearest, will seem to be pure lines when viewed from the furthest seats

Although 300 dots to the inch are required to give the idea of perfect continuity at the distance of one foot, it will shortly be seen that a much smaller number suffices to suggest it.

The cyclostyle, which is an instrument used for multiple writing, makes about 140 dots to the inch The style has a minute spur wheel or roller, instead of a point , the writing is made on stencil paper, whose surface is covered with a brittle glaze. This is perforated by the teeth of the spur wheel wherever they press against it The half perforated sheet is then laid on writing paper, and an inked roller is worked over the glaze. The ink passes through the perforations and soaks through them on to the paper below , consequently the impression consists entirely of short and irregular cross bars or dots

[1] Extract from a lecture on "The Just Perceptible Difference," delivered before the Royal Institution on Friday, January 27, by Francis Galton, F R S.

I exhibit on the screen a circular letter summoning a Committee, that was written by the cyclostyle. The writing seems beautifully regular when the circular is photographically reduced; when it is enlarged, the discontinuity of the strokes becomes conspicuous. Thus, I have enlarged the word *the* six times; the dots can then be easily seen and counted. There are 42 of them in the long stroke of the letter *h*.

The appearance of the work done by the cyclostyle would be greatly improved if a fault in its mechanism could be removed, which causes it to run with very unequal freedom in different directions. It leaves an ugly, jagged mark wherever the direction of a line changes suddenly.

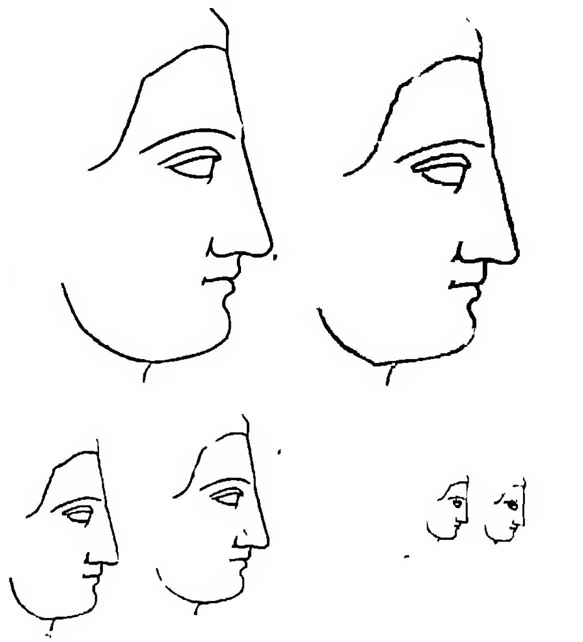
A much coarser representation of continuous lines is given by embroidery and tapestry, and coarser still by those obsolete school samplers which our ancestresses worked in their girlhood, with an average of about sixteen stitched dots to each letter. Perhaps the coarsest lettering that is ever practically employed is used in perforating the books of railway coupons so familiar to travellers. Ten or eleven holes are used for each figure.

A good test of the degree of approximation with which a cyclostyle making 140 perforations to the inch is able to simulate continuous lines, is to use it for drawing outline portraits. I asked the clerk who wrote the circular just exhibited to draw me a few profiles of different sizes, ranging from the smallest scale on which the cyclostyle could produce recognisable features, up to the scale at which it acted fairly well. Here are some specimens of the result. The largest is a portrait of $1\frac{1}{2}$ inches in height, by which facial characteristics are fairly well conveyed, somewhat better than by the rude prints that appear occasionally in the daily papers. It is formed by 366 dots. A medium size is $\frac{3}{4}$ inch high and contains 177 dots, and would be tolerable if it were not for the jagged strokes already spoken of. The smallest sizes are $\frac{1}{3}$ inch high and contain about ninety dots; they are barely passable, on account of the jagged flaws, even for the rudest portraiture.

I made experiments under fairer conditions than those of the cyclostyle, to learn how many dots, discs, or rings per inch were really needed to produce a satisfactory drawing, and also to discover how far the centres of the dots or discs might deviate from a strictly smooth curve without ceasing to produce the effect of a flowing line. It must be recollected that the eye can perceive nothing finer than a minute blurr of one three-hundredth part of an inch in angular diameter. If we represent a succession of such blurs by a chain of discs, it will be easily recognised that a small want of exactitude in the alignments of the successive discs must be unimportant. If one of them is pushed upwards a trifle and another downwards, so large a part of their respective areas still remain in line, that when the several discs become of only just perceptible magnitude, the projecting portion will be wholly invisible. When the discs are so large as to be plainly perceptible, the alignment has to be proportionately more exact. After a few trials it seemed that if the *bearing* of the centre of each disc from that of its predecessor which touched it, was correctly given to the nearest of the 16 principal points of the compass, N., NNE., NE., &c., it was fairly sufficient. Consequently a simple record of the successive bearings of each of a series of small equidistant steps is enough to define a curve.

The briefest way of writing down these bearings, is to assign a separate letter of the alphabet to each of them, *a* for north (the top of the paper counting as north), *b* for north-north-east, *c* for north-east, and so on in order up to *p*. This makes *e* represent east, *i* south, and *m* west.

To test the efficiency of the plan, I enlarged one of the cyclostyle profiles, and making a small protractor with a piece of tracing paper, rapidly laid down a series of equidistant points on the above principle, noting at the same time the bearing of each from its predecessor. I thereby obtained a formula for the profile, consisting of 271 letters. Then I put aside the drawing, and set to work to reproduce it solely from the formula. I exhibit the result; it is fairly successful. Emboldened by this first trial, I made a more ambitious attempt, by dealing with the profile of a Greek girl copied from a gem. I was very desirous of learning how far the pure outline of the original admitted of being mimicked in this rough way. The result is here; a ring has been painted round each



dot in order to make its position clearly seen, without obliterating it. The reproduction has been photographically reduced to various different sizes. That which contains only fifty dots to the inch, which is consequently six times as coarse as the theoretical 300 to an inch, is a very creditable production. Many persons to whom this portrait has been shown failed to notice the difference between it and an ordinary woodcut. The medium size, and much more the smallest size, would deceive anybody who viewed them at the distance of one foot. The protractor used in making them was a square card with a piece cut out of its middle, over which transparent tracing paper was pasted. A small hole of about $\frac{1}{8}$ of an inch in diameter was punched out of the centre of the tracing paper; sixteen minute holes just large enough to allow the entry of the sharp point of a hard lead-pencil were perforated through the tracing paper in a circle round the centre of the hole at a radius of $\frac{1}{4}$ inch. They corresponded to the 16 principal points of the compass, and had their appropriate letters written by their sides. The outline to be formulated was fixed to a drawing-board, with a T rule laid across it as a guide to the eye in keeping the protractor always parallel to itself. The centre of the small hole was then brought over the beginning of the outline, and a dot was made with the pencil through the perforation nearest to the further course of the outline, and this became the next point of departure. While moving the protractor from the old point to the new one it was stopped on the way, in order that the letter for the bearing might be written through the central hole.

A clear distinction must be made between the proposed plan and that of recording the angle made by each step from the *preceding one*. In the latter case, any error of

bearing would falsify the direction of all that followed, like a bend in a wire

The difficulties of dealing with detached portions of the drawing, such as the eye, were easily surmounted by employing two of the spare letters, R and S, to indicate brackets, and other spare letters to indicate points of reference The bearings included between an R and an S were taken to signify directive dots, not to be inked in The points of reference indicated by other letters are those to which the previous bearing leads, and from which the next bearing departs Here is the formula whence the *eye* was drawn. It includes a very small part of the profile of the brow, and the directive dots leading thence to the eye

The letters should be read from the left to the right, across the vertical lines. They are broken into groups of five, merely for avoiding confusion and the convenience of after reference

U, V, T are points of reference

By succeeding in so severe a test case as this Greek outline, it may be justly inferred that rougher designs can be easily dealt with in the same way

At first sight it may seem to be a silly waste of time and trouble to translate a drawing into a formula, and then, working backwards, to retranslate the formula into a reproduction of the original drawing, but further reflection shows that the process may be of much practical utility Let us bear two facts in mind, the one is that a very large quantity of telegraphic information is daily published in the papers, anticipating the post by many days or weeks The other is that pictorial illustrations of current events, of a rude kind, but acceptable to the reader, appear from time to time in the daily papers. We may be sure that the quantity of telegraphic intelligence will steadily increase, and that the art of newspaper illustration will improve, and be more resorted to Important local events frequently occur in far-off regions, of which no description can give an exact idea without the help of pictorial illustration, some catastrophe, or site of a battle, or an exploration, or it may be some design or even some portrait. There is therefore reason to expect a demand for such drawings as these by telegraph, if their expense does not render it impracticable to have them Let us then go into details of expense, on the basis of the present tariff from America to this country, of one shilling per word, 5 figures counting as one word, cypher letters not being sent at a corresponding rate. It requires two figures to perform each of the operations described above, which were performed by a single letter So a formula for 5 dots would require 10 figures, which is the telegraphically equivalent of 2 words, therefore the cost for every 5 dots telegraphed from the United States would be 2 shillings, or £2 for every 100 dots or other indications.

In the Greek outline there is a total of 400 indications, including those for directive dots, and for points of reference. The transmission of these to us from the United States would cost £8 I exhibit a map of England made with 248 dots, as a specimen of the amount of work in plans, which could be effected at the cost of £5 It is easy to arrange counters into various patterns or parts of patterns, learning thereby the real power of the process The expense of pictorial telegraphs to foreign countries would be large in itself, but not large relatively to the present great expenditure by newspapers on telegraphic information, so the process might be expected to be employed whenever it was of obvious utility

The risk is small of errors of importance arising from mistakes in telegraphy I inquired into the experience of the Meteorological Office, whose numerous weather telegrams are wholly conveyed by numerical signals. Of the 20,625 figures that were telegraphed this year to the office from continental stations, only 49 seem to have been erroneous, that is two and a third per thousand At this rate the 800 figures needed to telegraph the Greek profile would have been liable to two mistakes A mistake in a figure would have exactly the same effect on the outline as a rent in the paper on which a similar outline had been drawn, which had not been pasted together again with perfect precision The dislocation thereby occasioned would never exceed the thickness of the outline

The command of 100 figures from 0 to 99, instead of only 26 letters, puts 74 fresh signals at our disposal, which would enable us to use all the 32 points of the compass, instead of 16, and to deal with long lines and curves I cannot enter into this now, nor into the control of the general accuracy of the picture by means of the distances between the points of triangles each formed by any three points of reference Neither need I speak of better forms of protractor There is one on the table by which the ghost of a compass card is thrown on the drawing It is made of a doubly refracting image of Iceland spar, which throws the so-called "extraordinary" image of the compass card on to the ordinary image of the drawing and is easy to manipulate All that I wish now to explain is that this particular application of the law of the just perceptible difference to optical continuity gives us a new power that has practical bearings

POSTSCRIPT —A promising method for practical purposes that I have tried, is to use "sectional" paper, that is, paper ruled into very small squares, or else coarse cloth, and either to make the drawing upon it, or else to lay transparent sectional paper, or muslin, over the drawing Dots are to be made at distances not exceeding 3 spaces apart, along the course of the outline, at those intersections of the ruled lines (or threads) that best accord with the outline Each dot in succession is to be considered as the *central point*, numbered **44** in the following schedule, and the couplet of figures corresponding

11	21	31	41	51	61	71
12	22	32	42	52	62	72
13	23	33	43	53	63	73
14	24	34	**44**	54	64	74
15	25	35	45	55	65	75
16	26	36	46	56	66	76
17	27	37	47	57	67	77

to the portion of the next dot, is to be written with a fine pointed pencil in the interval between the two dots. These are subsequently copied, and make the formula. By employing 4 for zero, the signs of + and − are avoided, 3, standing for −1, 2, for −2, and 1, for −3 The first figure in each couplet defines its horizontal coordinate from zero, the second figure, its vertical one. Thus any one of 49 different points are indicated, corresponding to steps from zero of 0, ±1, ±2, and ±3 intervals, in either direction, horizontal or vertical Half-an-hour's practice suffices to learn the numbers The figures 0, 8, and 9 do not enter into any of the couplets in the schedule, the remaining 51 couplets in the complete series of 100 (ranging from 00 to 99), contain 21 cases in which 0, 8, or 9 forms the first figure only; 21 cases in which one of them forms the

second figure only, and 9 cases in which both of the figures are formed by one or other of them These latter are especially distinctive This method has five merits—medium, short, or very short steps can be taken according to the character of the lineation at any point, there is no trouble about orientation, the bearings are defined without a protractor, the work can be easily revised, and the correctness of the records may be checked by comparing the sums of the small coordinates leading to a point of reference, with their total values as read off directly "

A method of signalling is also in use for military purposes, in which positions are fixed by coordinates, afterwards to be connected by lines F G

BRITISH NEW GUINEA[1]

MR. THOMSON'S work on British New Guinea has been looked for with some impatience Now that it has come it falls short of our expectations We had hoped for a comprehensive work marshalling into order and summarising the observations and investigations made in the British part of New Guinea, by so many missionaries, explorers, naval and government officers and scientific men, for many years Instead of this we find that the book is made up almost entirely of the explorations during the past four or five years of the administrator, boiled down out of the official reports by Mr. J. Thomson, the secretary of the Queensland branch of the Geographical Society of Australasia Throughout the volume there is everywhere evidence that its author is new to literary composition In consequence, the terse and vigorous English of the original reports suffers severely in the process, so much so that we regret that their important parts have not been presented to us as extracts in the explorer's own words. Mr Thomson has himself never visited New Guinea, if we may judge by internal evidence, although his phraseology in many places is not unlikely to lead the reader to suppose that he has had a share in the results presented in its pages Had the author had some personal acquaintance with the country of which he writes he would have formed opinions, we believe, different from many of those he has expressed on his own account throughout the book

The work opens with a sketch "of the historical aspects of the whole of the great Papuan land," but we miss in it the names of many who deserve honourable mention for their contributions to the "making" of New Guinea We find no mention of the investigations of Dr Otto Finsch carried on in all three possessions, of those of Mr O Stone, of the missionaries in Geelvink Bay, of Mr Romilly, of the Special Commissioners Sir Peter Scratchley and the Hon John Douglas, of Mr Milman, and of Commanders Pullen and Field, who have all contributed to our knowledge of different regions

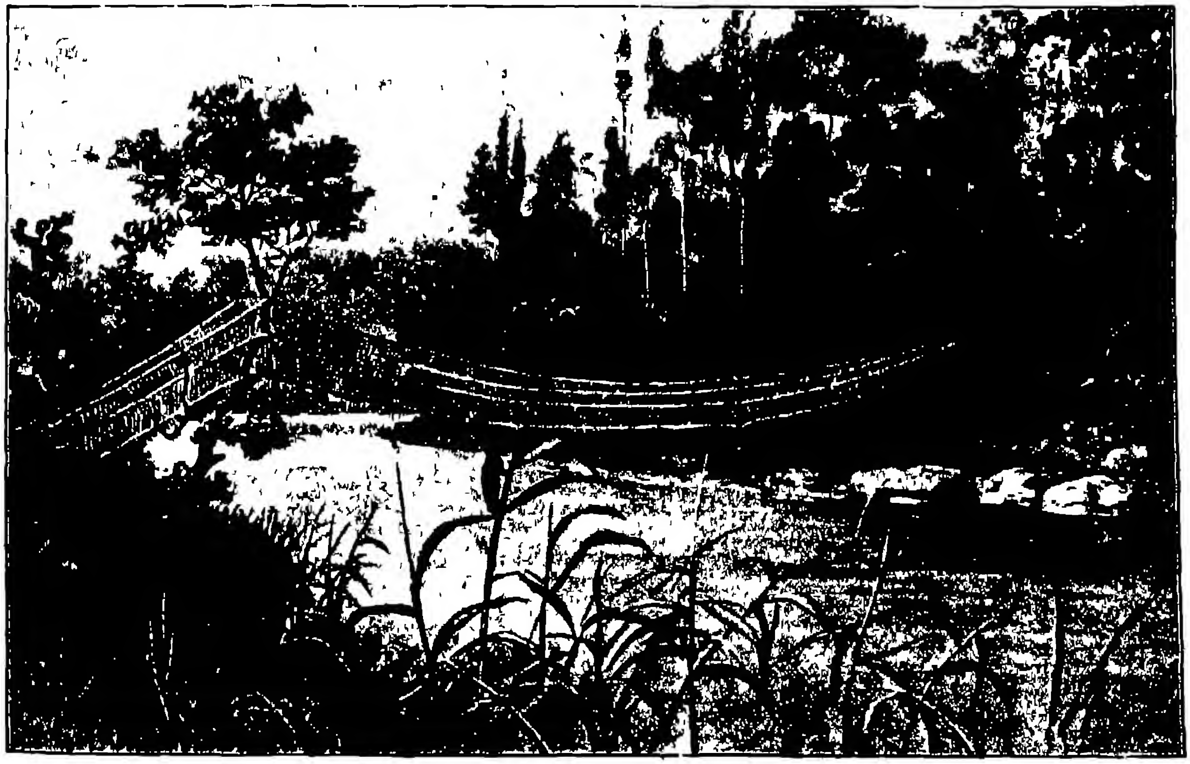

FIG 1 —Native suspension bridge across the Vanapa river

This chapter is prefaced by a quotation from the writings of Plinius Minor.—"It appears to me a noble employment to rescue from oblivion those who deserve to be eternally remembered, and by extending the reputation of others, to advance at the same time our own" These words are the true key-note of the book from which our Brisbane Pliny—Plinius Major—has never once deviated throughout his task It is doubtless no small compliment to any man to have his deeds held up in the light of "eternal remembrance" by one of his fellows, but the task requires the delicate hand of a judicious fellow, and we fear that our Pliny has marred the compliment in the paying. So inspired with veneration for his patron is he that every act of his appears almost extraordinary, and his name too august ever to be mentioned without the humblest obeisance expressed in the constant recapitulation of his titles, dignities, and office, which must be as nauseous to

[1] "British New Guinea" By J P Thomson, F.R S G S, &c (London George Philip and Co., 1892)

that officer as to every reader of Mr Thomson's book In this "noble employment," however, we hope that our historiographer for Papua may reap the reward hoped for by his prototype

The next two chapters deal with Sir William Macgregor's explorations in the Louisiade and D'Entrecasteaux archipelagoes In Chapter IV is an account of the pursuit and punishment of the natives of Chads and Cloudy bays for the murder of European traders visiting their shores The country lying to the south-east and north-west of Port Moresby forms the subject of the following two chapters Speaking of that portion to the south-east Mr Thomson says, "It may not be altogether unreasonable to assume that in the future . . fields once the scene of battle and feudal strife may be beautified by sites of local industry and manufacture, and enlivened by the joyous shouts of merry children and the harmonious peals of village bells" Quite forgetful of this happy picture, which he thinks is reasonable to expect, he sums up in the closing lines of his recapitulatory chapter the climatic aspects of the possession as "of an exceptional character, and their influence on Europeans so severe that very few constitutions can withstand their effect, a feature which will always be a great hindrance to settlement and a constant menace to life"—quite the region likely to produce European homes noisy with the "joyous shouts" of "merry children"! It is difficult to comprehend why Australian writers on New Guinea will so persistently—for Mr Thomson is not the only author who thus sins, nor have we quoted the only specimen of this style of writing in his book—overlaud the capabilities and "the vast natural and artificial resources" of the country, heedless whether they may induce their too trustful readers to embark in hopeless enterprises in this "never, never land"

FIG 2—Highlanders of Mount Musgrave

The seventh chapter, containing an account of Sir William Macgregor's splendid feat of the ascent of Mount Owen Stanley, is naturally the most interesting portion of the book During this expedition almost if not *the* only native bridge yet known in New Guinea was met with It was suspended from trees on each bank, and is very similar in every respect to those built by the Malays of Sumatra and the Dyaks of Borneo How elegant and picturesque a construction it is may be seen by the illustration on page 345

FIG 3.—Fly River natives.

On Mount Musgrave friendly relations were established with the highland tribes, and a photograph of great interest and value, which we are personally in a position to pronounce very characteristic, was obtained by Mr. Goodwin. This also, through the courtesy of the publishers, we are enabled to reproduce here (Fig. 2). Sir William

Macgregor says that the features of these people, which are "remarkably good, indicate more character and strength than those of the coast man, and the cheek bones in many are rather broad and prominent The nose is generally of the semitic type, with nostrils either not arched or much more so than is usual in Papuans The chin and under jaw are stronger" They may be compared with the Fly river people, also here figured (Fig 3)

European names were bestowed on the chief physical features of the country passed through by the expedition "of necessity," because of its "entire unacquaintance with their orthography (*sic*) through limited intercourse with the native inhabitants" This being in Dr Macgregor's case evidently a right and sufficient reason for the nomenclature bestowed, how can Mr Thomson with justice animadvert, as he does on an earlier page, on the fact that "the most important affluents [of the Kemp-Welch river] have received [from Mr Cuthbertson] European appellations? This disregard of the native nomenclature is, in the interests of geography, much to be regretted" However, we are pleased to learn that the European names selected by the administrator have been bestowed "upon the broadest national sentiment, as being compatible with the principles which prompted the bestowal of an English name on the range by the officers of H M S *Rattlesnake*" It is not improbable that the explorer of the Kemp Welch felt the same necessity, and was actuated by the same broad sentiment Evidently the actor here sanctifies the act We must, however, take exception to the statement made by Mr Thomson that it was to the *range* that the name Mount Owen Stanley was given It is evident from observations in his book, that the author is aware of the discussion that followed on the reading of Dr Macgregor's paper on his ascent of the mountain before the Royal Geographical Society in London. On that occasion the president of the society clearly pointed out that this name was bestowed, as has been marked on all maps for forty years, on the *peak*, not on the *range* Throughout the book this imperious disregard for nomenclature is exhibited D Albertis' name of Snake Point in the Fly river has without reason been changed to D'Albertis Junction, Annabel Harbour, close to Boundary Cape, although marked on the official map of Sir Peter Scratchley's voyage to the north-east coast, becomes Douglas Harbour, Fort Harbour, Clayton Inlet in Porlock Bay, and the peaks named on the same occasion, as well as the region delineated by the present writer at the base of Mount Owen Stanley, are also all ignored on the map attached to the volume now being considered One fails to comprehend what principle except personal feeling the author has followed, on the one hand in his agreeing to the change of the thoroughly established Mount Owen Stanley to a new name, and on the other, in his restoring to the Aird river, which had recently been re-christened the Douglas, the name given to it by Captain Blackwood half a century before Not only are these arbitrary changes an unwarrantable violation of the laws of nomenclature, but they are in the remover an illegitimate assertion of authority over previous fellow-explorers, as well as an assumption of an honour to which he has no title.

Mr Thomson has drawn on the face of his map two large red circles, from purely arbitrary centres of the equally arbitrary radius of 6° 8′ 56″, which are tangential somewhere in the valley of the Strickland river. It is impossible to divine their purpose, except perhaps to form a seasonable puzzle for his readers

The writer of this notice feels entitled to remark on the following observation, occurring on page 109 —"Although great care was exercised, the expedition was unable to identify places on the Owen Stanley range, named and described by Mr Forbes We are reluctantly constrained to omit these names." In the Proceedings of the Royal Geographical Society, which Mr Thomson quietly ignores, the writer has already pointed out that along the route by which the administrator approached Mount Owen Stanley, it would have been impossible to have seen the features "named and described by Mr Forbes." Mr Thomson, posing as a court of geographical appeal, has graciously condescended to intimate that if these names had been "judiciously and appropriately applied to well-defined places," they "would have received full recognition" from him "It is also," he continues, "regretable that in describing localities to which he assigns positions, that explorer has omitted to supply the data employed in their determination" To every unprejudiced person it must be evident that the map published by the writer could not have been plotted in England without data, any more than that of Sir William Macgregor, who has not supplied to the general public, so far as the writer knows, the data by which his localities are fixed It will be time, however, to submit to Mr Thomson these data, when it is acknowledged that a back parlour critic of a country in which he has never set foot is a competent judge of either the judiciousness and appropriateness of the names applied, or the accuracy of the localities, or the data on which they are based

Chapters VIII, IX, and X are devoted to an account of the administrator's ascent of the Fly river, and of his visit westwards to the Anglo-Dutch boundary, and the eleventh to his voyage along the north-east coast D'Albertis long ago gave us a very accurate account of his 400 mile navigation of the Fly river Sir William Macgregor carried his flag right to the German territory, and added several unknown rivers and new mountains to the map, but both in this region, as on the north-east coast, his voyages, though they contributed many additional facts, added little essentially new to the observations of his predecessors, except his account of the piratical Tugere tribe, living on our boundary line west of the Fly river, of whom so much had been heard but so little known

This handsome volume, which presents us in a collected form with the record of the important contributions, geographical and biological, of a most energetic officer, to our growing knowledge of New Guinea, would have been more valuable and welcome, even in its restricted range, but for the bias unduly exhibited throughout its pages, the verbiose platitudes by which it is marred, and the extreme looseness of its descriptions, as "Morna [an island] is of the usual formation," "features of oriental type," "the Papuan dialect," and such-like expressions, which are numerous In a long appendix we have a *résumé* of the results of the geological, botanical, and some of the zoological collections made by Sir W Macgregor and others Of these the chapter by Mr Etheridge, Government Palæontologist of New South Wales, is specially valuable. Several important zoological groups, however, such as the birds, are, curiously enough, entirely disregarded Vocabularies of many of the dialects spoken in widely separated districts of the possession are given, and are very valuable, and we sincerely hope that no opportunity may be lost of amplifying them In fine, we regret to feel that this work will not yet relieve those who desire to make themselves acquainted with the accurate and complete history of British New Guinea, from the labour of searching through the original reports of the explorations, not of the administrator alone, but of the many other equally trustworthy workers who have contributed to its records

HENRY O FORBES

NOTES

PROF R VIRCHOW will deliver the Croonian lecture before the Royal Society on March 16, the subject to be the position of pathology among the biological sciences

WE greatly regret to have to announce the death of Mr G M Whipple, Superintendent of the Kew Observatory He died on Tuesday night after a long illness.

THE *Journal of Botany* records the death, on January 18, at Brighton, of Dr Benjamin Carrington, the highest authority on British Hepaticæ

DR H J JOHNSTON LAVIS has been appointed Professor of Vulcanology in the University of Naples A chair of vulcanology existed for some time at Catania, but was abolished on the death of Prof Silvestri

SOME important work with regard to technical education in London was done by the London County Council on Tuesday The Council began the consideration of the recommendations of the special committee appointed to investigate the subject, and adopted the following proposals—that the Council should devote to technical education some portion of the funds from time to time recoverable under the Local Taxation (Customs and Excise) Act, 1890, that, in order to promote efficient and united action, it is desirable that the Council should delegate, so far as is permitted by law, its powers in respect of technical education to a composite body, to be called the Technical Education Board, to be appointed by the Council, partly from its own members and partly from other persons whose co operation is desired, and that the Board should be appointed for a term of three years It was agreed that the City Companies should be asked to contribute to the funds for technical instruction a fair proportion of their corporate income as distinguished from their trust property

ON Saturday the overhead electric railway at Liverpool was opened by Lord Salisbury, who afterwards delivered a very effective speech on the great things which are likely to be achieved for mankind by electricity

THE London Amateur Scientific Society will hold its annual general meeting on Friday, February 10, at 7 30 p m, at the Memorial Hall, Farringdon Street The president will deliver an address, and the officers and council for the ensuing year will be elected At the conclusion of the annual general meeting the ordinary meeting will be held, when objects of interest—botanical, zoological, and geological—will be exhibited

A CONVERSAZIONE was held the other evening at Firth College to celebrate the completion of the additional building The addition comprises new physical and biological laboratories, workshop and class rooms, and considerably increases the accommodation available for teaching purposes The cost, £5,500, has been wholly raised from local subscriptions

ANOTHER disastrous shock of earthquake occurred at Zante on Friday last It was followed by a terrific thunderstorm, accompanied by rain and hail All the ovens in the island were destroyed by the successive shocks, so that no bread or biscuits could be made Thousands of the inhabitants have been made homeless On Monday there were three further shocks. The King and Queen of Greece have visited several of the villages, and have been deeply affected by the scenes of utter ruin and desolation which have everywhere met their eyes. On Tuesday they visited the naphtha springs of the island, which are believed to be the centre of the disturbance The mayor of the village of Deme Elatia, some distance from the town of Zante, telegraphed that a large chasm, from which smoke was constantly issuing, had been discovered near that place

DURING the first part of the past week the weather in these islands was under the influence of barometrical depressions situated in the north-west. Rain fell in most places, and the temperature exceeded 50° in the south and west, and even reached 56° in London On Friday an anticyclone which lay over the Baltic, spread westwards, and under its influence the temperature became much lower, sharp frosts occurring at night over England, the readings on the grass in the southern part falling as low as 17°, but in the north and west the day temperatures were between 45° and 50° The weather in the southern parts of the country became bright and fine with local fogs, which extended as far as central England. During the early part of this week depressions from the Atlantic again skirted our western coasts in a north easterly direction, causing south-westerly gales in the north and west, and a considerable increase in temperature, the maxima on Monday exceeding 50° in Ireland and the extreme south-west of England The depression rapidly increased in intensity, and by Tuesday the warm south-west winds had spread over the whole country, the rise of temperature amounting to over 20° in the south east of England A bright aurora was observed in the north east of Scotland on Sunday night The *Weekly Weather Report* of the 4th instant shows that the temperature exceeded the mean in all districts during that week Bright sunshine did not differ materially from the mean in any district, the percentage of possible duration ranged from twenty five in the south-west, to twelve in the east of England

THE *American Meteorological Journal* for January contains an article by Prof D P Todd bearing upon the selection of stations for observing the total eclipse of April 16 next, together with a map showing the entire region of visibility He has gone to considerable trouble in collecting data, especially cloud observations for the month of April, for the last three years, together with particulars respecting the stations and the best means of reaching them The utility of a systematic examination of the cloud conditions of the eclipse localities is apparent It is only in this way that the best observing stations can be selected

THE meeting of the American Psychological Association at the University of Pennsylvania on December 27 and 28 seems to have been very successful According to a writer in the New York *Nation*, no one who attended the meeting failed to be impressed with the quite unusual enthusiasm of the members and the still more unusual peace and serenity that prevailed in all the discussions This writer is of opinion that, apart from Dr Sanford's observations on dreams, the paper of most general interest was President Hall's account of the history and prospects of experimental psychology in America A "breezy stimulus" was brought to the meeting by Prof Hugo Munsterberg, of Harvard, who has recently gone from Freiberg to be director of the Harvard Psychological Laboratory He stirred up a vigorous discussion upon the very foundations of experimental research This discussion, as well as others, was enriched by the contributions of Prof Titchener, of Cornell The next meeting of the association is to be held at Columbia College, New York, during the Christmas recess, 1893

THE Annual Report of the Botanical Department, Jamaica, has just been published The Director, Mr W Fawcett, F.L S, has a good deal to say about the work of his Department, one of the oldest and most successful in the colonies It was started as long ago as 1777, and ever since, as Mr Fawcett recalls, it has successfully "introduced valuable exotics, and the productions of the most distant regions to the West Indies," and laid the foundations of the present prosperity in place of the poverty which followed the abolition of slavery The work of establishing the Hope Gardens as the headquarters of the Department near Kingston is still kept in view, although the amount allowed for this purpose appears much less than the Director considers desirable, taking into account the present importance of the island A hill garden is looked upon as essential to the development of the high lands in Jamaica, and Mr Fawcett shows that as about one half of the total area of the island is above 1000 feet elevation, it is impossible to ignore the

legitimate claims of those who are engaged in cultural industries above that limit Good progress has been made in the scientific work connected with the herbarium and library, and numerous subjects, such as the extension of grape culture, the distribution of valuable economic plants, experiments in onion and tomato culture, fodder plants for the hills, have received attention. Students from Harvard University were engaged during the year in studying and making collections of tropical plants, and one of these devoted himself to preparing glass models of flowers and fruits with dissections to illustrate the science of botany Two apprentices, natives of Lagos, West Africa, were attached to the Hope Gardens, with the view of qualifying themselves to take charge of botanical stations in their own country

MR. FAWCETT's opinion respecting the practical aims and functions of departments like his are conveyed in the following words "Botanic Gardens in the tropics do the work on the plant side of Agricultural Departments in temperate climates They are in themselves experimental stations, and are much more efficient in introducing new cultural products, and in distributing plants and imparting useful information than most agricultural departments The whole of the Botanic Gardens in the British Empire are more or less in communication with one another, exchanging seeds and publications, and all look up to the Royal Gardens at Kew as to their head for advice and assistance Imperial Federation is already in existence as regards the Botanical Gardens and their work If any special variety of plant or any new culture comes into notice information and plants are sought either directly from the local institutions, or more probably through Kew as the botanical clearing house The Director of Kew has at his disposal the services of experts in every branch of botanical inquiry, and he is always most willing to assist colonial establishments in every way Besides, any intricate question that arises in chemistry, in diseases of plants, in insect pests, in the commercial value of new products, can nearly always be determined by reference to Kew Colonial botanical gardens are therefore not isolated units, but branches of an organisation as wide as the British Empire itself"

THE first part of "A Handbook to the Flora of Ceylon," by Dr H Trimen, F R S, director of the Royal Botanic Garden, Paradenyia, will shortly be published It will be illustrated by twenty-five coloured plates, and the entire work is intended to consist of four similar parts

THE first number of *Erythea*, a new monthly botanical journal for Western America, has been published It is edited by Mr Willis L Jepson, under the direction of members of the botanical department of the University of California

MR T SOUTHWELL records in the February number of the *Zoologist* the occurrence of Sowerby's whale (*Mesoplodon bidens*) on the Norfolk coast On December 19 last he received a telegram stating that a strange "fish" was ashore at Overstrand, near Cromer, and on the following day he and Mr. S. F Harmer, of the Museum of Zoology and Anatomy, Cambridge, went to Overstrand, where they found an adult female of this rare species About 8 a m, on Sunday, December 18, one of the Overstrand fishermen saw from the cliff an object lying in shallow water near the beach, which he at first took to be a log of wood, but soon perceived to be a large "fish." After obtaining assistance, he fastened a noose over its tail and secured it by an anchor, till it was placed on a trolley and drawn up the gangway to a shed on the cliff where the visitors saw it. The animal was alive when first observed, but died before it was taken from the water. Before the arrival of the visitors it had been eviscerated, and a very advanced fœtus removed from it, The total length of the old female, measured in a straight line to the centre of the tail, was 16 feet 2 inches, and that of the young one 5 feet 2 inches, across the flukes of the tail the adult measured 3 feet 8 inches The present, says Mr Southwell, is the nineteenth known example of this remarkable animal, all of which have been met with in the North Atlantic during the present century, but, with the exception of one taken in 1889 at Atlantic City, which came into the possession of the United States National Museum at Washington, and of which no account has, he believes, at present been published, in no other instance has an example in perfect condition come under the notice of a cetologist Individuals or their remains have been found in Scotland and Ireland, but the only previous English example was met with at the mouth of the Humber in September, 1885

COLONEL H W FEILDEN, in the course of an interesting paper on animal life in East Greenland, contributed to the February number of the *Zoologist*, suggests, as he has done before, that the Musk ox might with advantage be introduced into Great Britain He sees no reason why it should not thrive on the mountains of the Highlands of Scotland In the winter season the Musk ox is covered with a long stapled fine wool in addition to its coat of hair This wool is of a light yellow colour, and as fine as silk. Sir John Richardson states that stockings made from this wool were more beautiful than silk ones Young Musk-oxen are very easily reared and tamed, and, Colonel Feilden thinks, there could not be any great difficulty in catching either old or young in Jameson's Land

GOVERNOR FLOWER has recommended that all of the New York State's pecuniary contributions to agriculture should be turned over to Cornell University, with power to apply the same in such a manner as the trustees and faculty of that institution may devise To the New York *Nation* this seems an excellent suggestion The agricultural disbursements from the State Treasury, except the portion specifically set apart as premiums for agricultural fairs, have become, it says, as distinctly a part of the "spoils system" of politics as the work on the canals or the appointments of wardens in the State prisons The Dairy Commission was started with an appropriation of 10,000 dollars for the purpose of suppressing oleomargarine The expenditure has grown to 100,000 dollars per year, while the fight against oleomargarine is not a whit more effectual than it was in the beginning

THE Government of Cape Colony has now at work, in charge of its own experts, eight water-boring diamond drills, and there is a great demand on the part of farmers for the use of the instruments Experiments have been made on twenty seven farms, on twenty-two of which water has been found The *Agricultural Journal* of Cape Colony says that the results have sometimes been astonishingly successful On a farm in the division of Colesberg, for instance, three holes were sunk, the first two unsuccessfully In the third, however, the water was struck, first at 2 feet 6 inches, then at 8 feet 6 inches, then at 16 feet, then 22 feet, then 32 feet 6 inches, and on reaching a depth of 47 feet a stream of water shot up above the ground, gauged at 21,600 gallons in twenty-four hours, delivered through a 1-inch pipe, and with every indication of the supply proving permanent. In most cases the water is of excellent quality Some exceedingly interesting experiments are about to be tried in Bushmanland by the Government Sites are now being selected for a line of boreholes right across the country It is well known that the veld makes splendid sheep runs after occasional rains, and should the experiments prove successful, the value of the land will be greatly increased With respect also to the Government railway grant of 6000 square miles of land in Bechuanaland, it is intended that water shall be bored for there as soon as drills can be set at liberty

PROF O C. MARSH gives in the February number of the *American Journal of Science* an interesting restoration of

Anchisaurus, the skeleton chosen for the purpose being the type specimen of *Anchisaurus colurus*, which the writer has already described This restoration, as shown on an accompanying plate, indicates that *Anchisaurus colurus* was one of the most slender and delicate dinosaurs yet discovered, being only surpassed in this respect by some of the smaller bird-like forms of the Jurassic. The restoration, Prof Marsh thinks, will tend to clear up one point long in doubt The so-called "bird-tracks" of the Connecticut river sandstone have been a fruitful subject of discussion for half a century or more That some of these were not made by birds has already been clearly demonstrated by the fact that the impressions of fore feet, similar to those made by reptiles, have been found with them Although no osseous remains were found with them, others have been regarded as footprints of birds, because it was supposed that birds alone could make such series of bipedal, three-toed tracks and leave no impression of a tail It is now evident, however, says Prof Marsh, that a dinosaurian reptile like *Anchisaurus* and its near allies must have made footprints very similar to, if not identical with, the "bird tracks" of this horizon On a firm but moist beach, only three toed impressions would have been left by the hind feet, and the tail could have been kept free from the ground On a soft, muddy shore, the claw of the first digit of the hind foot would have left its mark, and perhaps the tail also would have touched the ground Such additional impressions the writer has observed in various series of typical "bird tracks" in the Connecticut sandstone, and all of them were probably made by dinosaurian reptiles No tracks of true birds are known in this horizon

THE U S Secretary of the Interior, in his report, just issued, for the fiscal year ending June 30, 1892, refers to a good many subjects of more than passing interest Speaking of Indian educational work during the year, he states that it has been greatly extended and improved The attendance of Indian children in school has increased over 13 per cent, the enrolment for 1892 being 19,793 as against 15,784 in 1889 Five new Indian reservation boarding schools have been established during the present administration, and are in successful operation, and six others are in process of establishment, and it is anticipated will be opened soon Six non-reservation schools have also been established and others are being prepared The standard, character, and ability of all *employés* have been greatly improved, as have also the appliances and equipments for the proper training of Indian pupils and the efficient administration of the Indian school service A uniform system of text-books and course of study has been adopted, and a compilation of the rules for the conduct of the schools has been prescribed The interest in the welfare of the Indians has been constant and the work in their behalf persistent, and the Secretary thinks that this has resulted in their being raised still nearer to civilisation

THE U S Geological Survey, according to the Secretary for the Interior, has had a very marked effect on the mining industries of the country The increase in value of mineral products during the past year was 75,000,000 dollars, and the increase during the thirteen years since the institution of the survey is 300,000,000 dollars. While a part of this development represents the normal growth of the population and industries, the increase is much more rapid than that of population, and is, moreover, accompanied by a decided relative decrease in importations of mining products, indeed, the mining products of the country have more than doubled during the past thirteen years, while the population has increased only 30 per cent. The secretary, therefore, thinks it fair to ascribe a material part of the present industrial activity in extracting and utilising mineral resources to the services of the Geological Survey through its correspondence, and especially through its widely distributed maps and reports. The cost of mineral production during the past year has been reduced about 15 per cent, and during the period since the institution of the survey no less than 40 per cent, a saving to the consumers of mineral products amounting to millions of dollars annually being thus effected A considerable part of this saving must be ascribed to the diffusion of exact information concerning mineral localities by the geological surveys of the Federal Government and several of the States.

DEALING with the state of the Seal Islands, the Secretary for the Interior says that during the season of 1892 only 7500 seals were killed on the islands, and that the diminished number of seals upon the rookeries shows the terrible waste to seal life in the destructive methods employed in pelagic sealing Heroic measures, he maintains, are necessary for the preservation of the sealing industry In 1890 no less than 50,000 seals were taken in the sea, and more than that number in 1891 Every seal taken in the ocean represents many more destroyed, and the 52,087 taken in the ocean in 1891 indicates the destruction of 300,000 more, three-fourths of which were females

THE accumulation of ice in winter, blocking harbours, estuaries, &c, interferes greatly with the commerce of Northern peoples The idea arose to make steamers which should break a temporary path through the ice, and in Gothenburg (Sweden) such a vessel was built in 1881 In the severe winter of 1885 it made a wide passage between that town and Vinga, on the open sea, through an ice-bank about a foot thick, which it charged at a speed of about 8½ knots an hour Christiania has been led to get one of these ice breaking steamers, also Oersen in Denmark, and Stockholm The *Murtaja*, recently built for Stockholm (and described in *Génie Civil*), acts both by its weight in charging the ice bank, and by its spoon-like bow resting on the ice and crushing it. The hull is divided into compartments, those at the bow and stern serving as reservoirs for water, which is transferred from the one to the other by a pump With the stern reservoir full, the draught of water at the stern is about 21 inches, at the bow about 15 inches When the bow rises on the ice the water is quickly brought forward to add to the weight It need hardly be said the bow, and indeed the whole of the hull, are made very strong, the material used being Swedish scrap iron and Martin steel

IT is known that sewage water, spread over irrigation fields, reappears from drains placed at a few feet depth, in a limpid state, like spring water. This water, unlike that of sewers, proves remarkably favourable to fishes, probably because of its dissolved organic matter, which the filtration in the soil has not wholly removed. This fact has been lately observed by Herr Oesten on the irrigation farm at Malchow, near Berlin, where the water is collected in eight ponds, and in these ponds salmon and carp have flourished greatly.

IN determining the thermal conductivities of liquids, two methods have been employed In the one, a column of liquid is warmed at the top and the rate of propagation downwards through the column is observed In the other, the lamellar method, which was first employed by Guthrie, a thin layer of liquid is placed between two conducting surfaces Mr R Wachsmuth has shown, by means of an ingenious piece of apparatus, that in the first method currents in the liquid are unavoidable. The apparatus, as described in *Wiedemann's Annalen*, consisted of a beaker placed inside another containing water. The inner beaker was filled with water and blue iodide of starch, which has the property of suddenly turning colourless when heated to a temperature somewhere between 30° and 70°C according to the degree of dilution. A copper cylinder was placed on the rim of both beakers so that its bottom was in contact with the surface of the emulsion. When steam was

made to pass through the cylinder, a colourless stratum was seen to extend downwards from the surface The separating surface was sharply defined at first, but after a few minutes a number of secondary stratifications appeared, which on close inspection showed wavy outlines Many of them were of a deeper blue, *i e.* cooler, at their upper than at their lower surfaces, so that there was evidence of a vortex-like motion in the liquid. For really trustworthy results Mr Wachsmuth used an arrangement of two copper plates and a thermopile, the lower plate being placed in contact with ice

THE volume on "The Partition of Africa," by Mr J Scott Keltie, which has been for some time in preparation, will be issued in a few days by Mr Stanford. The work, which has been brought thoroughly up to date, is illustrated by a carefully-selected series of facsimiles of early maps, as well as by a number prepared specially to show the present condition of the continent in its many different aspects.

MR A E SHIPLEY, Fellow of Christ's College, Cambridge, and Demonstrator of Comparative Anatomy in the University, has been for some time engaged on an illustrated text-book of invertebrate zoology, which will be published (Adam and Charles Black) early in the spring. It is specially adapted for the use of University students reading for such examinations as the first part of the Natural Sciences Tripos, or for the B Sc. degree in London

MESSRS MACMILLAN AND CO have published a second edition of Mr D E Jones's "Examples in Physics" The book has been carefully revised, and some sixty pages of matter have been added New sets of problems from recent papers have been put in the place of the examination questions at the ends of the chapters

THE first volume of the *Seismological Journal* is now in the press, and will shortly be issued It is uniform in size and in character with the Transactions of the Seismological Society, and will correspond with what would have been volume XVII of those publications had they been continued The yearly subscription for the journal is 5 yen, 5 dollars, or £1 This includes delivery or postage It may be paid by P O O or a draft on any foreign bank in Yokohama Address, John Milne, 14, Kaga Yashiki, Tokio

MESSRS WHITTAKER AND CO have published "The School Calendar and Handbook of Examinations, Scholarships, and Exhibitions, 1893" This is the seventh year of issue A preface is contributed by Mr F Storr.

A DEFINITELY crystallised compound of iron and tungsten of the composition FeW_2 is described by Drs. Poleck and Grützner, of the University of Breslau The crystals of this interesting substance were discovered in drusy cavities of a massive piece of a crystalline iron tungsten alloy containing no less than 80 per cent of tungsten The alloy had been prepared by an electrolytic process from *wolframite* at the works of Biermann's Metal Industry in Hanover, and exhibited in the numerous cavities small but very well formed crystals of a silver-grey colour and exhibiting very brilliant faces They were extremely heavy and of exceptional hardness Upon analysis they yielded numbers corresponding closely with those calculated for the compound FeW_2. Dr. Milch, of the Mineralogical Department of the University, subjected the crystals to a goniometrical investigation, and found them to consist of trigonal prisms whose faces were inclined exactly at 60°, and which were terminated by a basal plane inclined exactly at 90°. Singularly, however, no other faces were ever discovered upon them, so that it was impossible to ascertain to what sub section of the hexagonal system the crystals belonged. The crystals are so hard that they readily scratch topaz, and appear to be of about the same hardness as corundum

THE discovery of these crystals of a definite compound of iron and tungsten, and the fact that they are endowed with such a high degree of hardness, afford a ready explanation of the long known property of tungsten in improving the hardness of steel Berzelius, in his *Lehrbuch*, already remarked that tungsten readily formed alloys with most of the other metals, and in the year 1858 Muchet in this country took out a patent for the employment of tungsten in the manufacture of steel Thereupon the wolfram minerals, previously considered as almost worthless, rapidly came to acquire a considerable value Bernoulli has since shown that tungsten is capable of alloying in all proportions with iron until it reaches a proportion of 80 per cent, when the mass becomes infusible even at the hottest procurable white heat This alloy containing so high a percentage of tungsten, approximating indeed to that (86 4) contained in the crystals above described, exhibits a silver-grey lustre like that of the crystals and possesses almost the same hardness, scratching glass and quartz with ease Latterly the manufacture of this alloy has been carried on at the Hanoverian metal works above referred to, and brought into commerce. There can be little doubt that the remarkable property of tungsten in increasing the hardness of steel is due to the formation of more or less of this compound FeW_2, and the nearer the proportions of the two metals approach to those of the compound itself the more nearly does the resulting alloy approach in hardness to that displayed by the crystals of FeW_2 above described

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*, ♀) from India, presented by Capt U Cooke, a Two-spotted Paradoxure (*Nandinia binotata*) from West Africa, presented by Lady Fleming, a Brush-tailed Kangaroo (*Petrogale penicillata*, ♂), two Black striped Wallabys (*Halmaturus dorsalis*, ♀ ♀) from New South Wales, presented by Mr Wilberforce Bryant, a Mauge's Dasyure (*Dasyurus maugei*) from Australia, presented by Mr Robert Hoare, a Red and Yellow Macaw (*Ara chloroptera*) from South America, presented by Mr. H H. Dobree, a Grey Parrot (*Psittacus erithacus*) from West Africa, presented by the Executor of the late Mrs Bolaffe, an Æthiopian Wart Hog (*Phacochærus æthiopicus*, ♂) from Matabeleland, South Africa, deposited, two Chukar Partridges (*Caccabis chukar*, ♂ ♀) from North-west India, presented by Major Ingoldsby Smythe, fourteen Prairie Marmots (*Cynomys ludovicianus*, 6 ♂ 8 ♀) from North America, an Arctic Fox (*Canis lagopus*) from the Arctic Regions, two Rufous Tinamous (*Rhynchotus rufescens*) from Brazil, purchased, three Black and Yellow Cyclodus (*Cyclodus nigro luteus*), three Diamond Snakes (*Morelia spilotes*), a Short Death Adder (*Hoplocephalus curtus*), a Purplish Death Adder (*Pseudechis porphyriaca*), a North Australian Banded Snake (*Pseudonaia nuchalis*) from New South Wales, received in exchange

OUR ASTRONOMICAL COLUMN

COMET HOLMES (1892 III)—During the past week no very important change has taken place in the appearance of the comet, the following is the current ephemeris —

Ephemeris for 12h M T Paris

SPECTRA OF PLANETARY NEBULÆ AND NOVA AURIGÆ —In the December number of the *Memorie della Società degli Spettroscopisti Italiani*, among many interesting communications, is one by M Eugen Gothard, relative to the great similarity between the spectra of the late Nova and the planetary nebulæ By the aid of a 10½-inch reflector and a 10-inch objective prism, together with Schleussner's orthochromatic plates, he has been able to obtain these photographs, the wave-lengths of the lines of which are given in the table below In the memoir copies of the photographs on a somewhat larger scale are given, that of the Dumb bell nebula (G C No 4447) showing the image of the nebula itself, just as if no prism had been used The wave-lengths of the Nova given in this table were obtained from photographs taken on September 27 with 2h 15m exposure, and on October 28 with 3h exposure, and, in M Gothard's words, "gave the surprising result that the spectrum of the new star perfectly agrees with that of the planetary nebulæ "

The following is the table of the wave lengths, lines I, II, VI, and VII representing the nebula lines, and III, IV, and V the hydrogen lines —

		I	II	III	IV	V	VI	VII
(1) G C No 4447	—	502	—	434	411	396 5	386 5	373

SUN SPOTS AND MAGNETIC PERTURBATIONS IN 1892 —In an article under this heading in *Astronomy and Astrophysics* for January M Ricco brings together the facts relative to these two phenomena, the magnetic perturbations being taken from the photo magnetographs of the United States Naval Observatory As the author describes in detail both kinds of observations, and in addition, a tabulated statement of the records, we cannot do better than abridge the table, by omitting the numerical statements as to the magnitudes of the spots and perturbations, leaving our readers to refer if necessary to the journal itself

In the column "spots" this means principal spots, E denotes extraordinary, V L, very large, L, large, M, medium, S, small, and N, none

Transit Centre Meridian	Spots	Helio-graphic latitude	Time of Maximum	Mag Perturbations	Retardation in time. h
Jan 4, 2 p m	V L	+20	Jan 6, 4 a m	V L	38
Jan 28, 3 p.m	L	−16	Jan 29, noon	L	21
Feb 2–4	N	—	Feb 2–4	S	—
Feb. 12, 4 a m	E	−30	Feb 14, 1 a m	E	45
March 1–5	N	—	March 1–5	M	—
March 7, 2 a m	N	—	March 7, 2 a m	L	—
March 10, 2 p m	E	−29	March 12, 11 a m	V L	45
April 23, 8 p m	L	+11	April 25, 11 p m	L	51
April 24, 4 p m	L	+16	April 26, 1 p m	L	45
May 1–2	N	—	May 1–2	M	—
May 16, 5 p m.	E	−16	May 18, 6 p m	E	49

From this table some very interesting facts may be gathered Out of the eleven cases which M Ricco gives, no less than seven instances occur where the passage of the spots over the central meridian is followed by a terrestrial magnetic disturbance, and not only this, but the magnitudes of both vary directly The point which the author wishes to emphasize most is the apparent constancy of the interval of time between these two phenomena, and an important fact is that at both appearances of the great February spot the same retardation occurred In the above table, with the exception of January 29, the mean interval is 45½ hrs, "thus indicating a velocity of propagation from the sun to the earth of about 913 kms per second," or "more than 300 times less than that of light "

NEW MINOR PLANETS —Photography seems to be rapidly increasing the number of our minor planets, that is to say, if the announcements really refer to new ones Wolf and Charlois between them have discovered five this year, the former two (1893 B and C), the latter three (1893, A, D, and E)

THE LUNAR SURFACE —At the present day the general idea with regard to the peculiar features of the moon is that they are the results of stupendous volcanic actions, the number and activity of which surpassed anything that we can imagine Owing to the extraordinary circularity in the craters, ring plains, walled plains, and to the well-known fact that many of the craters have not the raised lava floor half way up or near the summit of the cone, which is such a typical terrestrial characteristic, doubt as to their volcanic origin has often been raised In a small pamphlet which we have received from Mr S E Peal, Sibsagor Assam, the author suggests a "theory of glaciation" in the light of recent discoveries with regard to the maximum surface temperature, and also to the non viscosity of ice at low temperatures, together with the admitted possibility of snow existing on the moon The author assumes the moon to be constituted somewhat like our earth, and at one time to have been at a higher temperature, having an atmosphere, water, &c, and draws attention to the facts that there are no polar caps, that colour is conspicuous by its absence, "a feature quite opposed to terrestrial experience, except at the poles," and therefore "may not the entire globe be swathed in snow?", and the absence of river valleys and drainage sculpturing, indicating that a piling up of dry material has taken place in opposition to a fluvial erosion At the time when the lunar globe had so far cooled down as to be practically rigid, the tidal action would gradually turn all continents and land surfaces into shoals, and at the temperate stage of development the growth of the polar caps would be restricted to the shallows, extending from them as the temperature became reduced This advancing sheet of ice would sometimes be deformated by submarine heat vents resulting in a large or small bay, depending on the magnitude of the vent Extending seawards the "horns of the bay would meet around and enclose this area of higher mean temperature, converting it into a lagoon" Nocturnal radiation and solar heat alternately would perhaps freeze and thaw the ice formed thereon, and with a rare atmosphere and intense cold aqueous vapour would arise from "the water (floe-covered) floor during the day at least, and be carried over the ice edge by diffusion when the fall in temperature would precipitate it into snow, thus gradually forming a vast rampart" Century after century would see the level floor gradually lowered, and the ramparts increased in height The author accounts for all the peculiar forms of craters, walls, &c, by different local conditions (i e land or water or submarine vents), but they are all the result "of water floors left in a slowly extending glaciation of the crust."

GEOGRAPHICAL NOTES

AT the French Congress of Learned Societies, which meets on April 4 at the Sorbonne, the section of historical and descriptive geography, is to be devoted specially to the early geographical conditions of France, and to the work of French travellers. The programme includes the consideration of the earliest traces of human habitations, maps of caverns, &c, and proceeds to classify existing dwellings according to their situation and altitude Local names in danger of falling out of use are to be collected, and the limits of the old districts such as Brie, Beauce, Sologne, &c, to be investigated in order to place on record the geographical conditions which led to their formation

IN the *Scottish Geographical Magazine* for February Mr J G Goodchild gives a most interesting description of a large scale topographical model of the site of Edinburgh, which he has recently constructed. The model, which is on exhibition

in the Museum of Science and Art, Edinburgh, is based upon Bartholomew's map of Edinburgh on the scale of 15 inches to a mile, but the altitudes are taken point by point from the large town plans of the Ordnance Survey The model is in many ways original in its mode of construction Its object is purely geographical, having been suggested by a leading citizen as a method of showing the contrast between the circuitous roads and frequent steep gradients of the old coaching days, and the straighter and more level lines of communication by which modern engineers have overcome the restraint of physical configuration

IN the same number of the *Scottish Geographical Magazine* there is a paper on the Deserts of Atacama and Tarapaca, read to the Society by Mrs Lilly Grove, and some interesting notes on South Eastern Alaska by Prof J J Stevenson, illustrated by a map.

MR. H J MACKINDER's third educational lecture for the Royal Geographical Society was given on Friday night, the subject being the belt of Steppe which traverses Asia from west to east He showed how the distinctive physical and climatic conditions of the Steppe favoured the growth of nomadic nations, every man of whom was a member of the most mobile cavalry force which ever existed Pastoral pursuits and marauding were natural to the Steppe peoples, and the descent of their hordes on the settlements bordering the Steppe were turning points in the history of surrounding nations. Reference to the successive periods of conquest by the Scythians, Huns, Turks, and Mongols showed the power of these nomads on the affairs of other countries, and until the advent of the Steppe bred Cossacks no western power has ever secured control of the central Asian plains

FOLLOWING on the death of Captain Stairs we have to record the death of his fellow-officer in the Emin relief expedition, Mr R H Nelson Mr Nelson returned to Africa, and was in charge of the district of Kikuyu in Ibea, when he succumbed to an attack of dysentery on December 26, 1892

THE INSTITUTION OF MECHANICAL ENGINEERS

THE first general meeting for this year of the Institution of Mechanical Engineers was held on Thursday and Friday evenings of last week, the 2nd and 3rd inst , in the theatre of the Institution of Civil Engineers

There were two papers set down for reading, as follows — "Description of the experimental apparatus and shaping machine for ship models at the Admiralty Experimental Works, Haslar," by R. Edmund Froude, of Haslar , "Description of the pumping-engines and water-softening machinery at the Southampton Waterworks," by William Matthews, waterworks engineer

After the disposal of the usual formal business, the President (Dr. William Anderson) referred to the International Engineering Congress which was to be held in Chicago during the month of August next He had received a letter from Mr James Dredge, of London, who had been elected honorary president of the congress. Every one, Dr Anderson said, knew of Mr Dredge, so there was no occasion for him to say anything further on that head , but he trusted that English engineers would take steps necessary to a creditable representation

The next business was an alteration in the bye laws, the chief referring to the class of membership Hitherto the institution has consisted of members, associates, and graduates The two latter classes are, however, of small importance and practically the institution is composed of full members. The qualification for membership was that the candidate should be an engineer not under twenty four years of age , so that a member might be a Great George Street magnate, or the head of a big engineer ing firm, down to a draughtsman or the foreman of a machine shop, supposing of course he were an engineer and not simply a mechanic or artisan. These conditions of equality do not appear, however, to meet the views of the council of the Institution, so there are to be two classes of engineers on the register, the big and the little These are to be known respectively as members and associate members, but as far as we can see the broad distinction is that the member has achieved success whilst the associate member has still his way to make Honour to whom honour is due is a good maxim, but it may be doubted whether the practically self-elected council of an irresponsible body should be the arbiters, not only of fame, but of professional status

Resolutions embodying the proposed changes were moved from the chair, and carried unanimously It need not be said that the new rule is not retrospective

These matters having been settled, the secretary proceeded to read Mr Froude's paper describing the apparatus in the Haslar establishment, over which he presides To make clear the details of mechanism given would be quite impossible without the aid of drawings These were supplied at the meeting in the shape of wall diagrams, but as members had not an opportunity of studying them beforehand, there were very few who were able to keep up with the reading of the paper, excepting those who already knew all about the matter This is too often—we may say generally—the case in meetings of the technical societies , excepting always the Institution of Civil Engineers Before this Society a paper is read on one evening, and, if its importance be sufficient it is discussed during three sittings, each a week apart Members have therefore an opportunity of grasping the details of the papers read, and preparing what they have to say beforehand It is for this reason that the discussions before the Civil Engineers have always been instructive

Mr Froude's paper deals with but a fragment of its subject, but it takes the part which was more especially of interest to his audience namely, the mechanical details involved in the apparatus used for testing the models by which a forecast is made of the performance of future naval vessels It is well known that these forecasts are made possible by the late Mr Froude's discovery of the law of "corresponding speeds," so that the speed, with a given power, of the full sized ship can be deduced from the performance of the model The way in which the late Mr Froude carried out his investigations, and how the original experimental works grew up at Torquay, under the wise encouragement of the Admiralty, are well known to all interested in physical science It would be difficult to overestimate the good that has followed this work , for one thing it has done much to put us on an equality with our old rivals, the French—long, indeed, our masters in the science of ship design Perhaps there is nothing upon which we could better found our claim to naval supremacy—in this long era of naval peace—than the possession of the only naval testing tank of its kind It is a distinction we shall probably not long be able to boast, for the Russians, Italians, and Americans all contemplate constructing establishments of a like nature

The paper commences with describing the principal features of the present Admiralty experiment establishment at Haslar As at the former works at Torquay, the chief object consists of a long covered water-way, in which models of ships are towed to ascertain their resistance The towing is done from a dynamometer carriage driven at definite speeds by a stationary engine working a wire rope The models are made of hard paraffine, generally about 14 feet long, and something upwards of 1 inch in thickness as finished. They are cast in a mould with an allowance of about ¼" for finishing the shape The latter operation is done by hand, guidance grooves being cut in the model, so that the exact form may be preserved The working of this shaping or copying machine, and the way in which it enables the lines of a drawing to be translated into model form, constitute one of the most interesting parts of the installation The water-way, canal, or tank at Haslar is nearly 400 feet long, and of nearly uniform section throughout The sides are of concrete and vertical, and the railway, on which the dynamometer carriage runs, is bedded on the tops of the side walls of the water-way, in place of being suspended over the water from the roof, as in the original design The experimental carriage, which has to be nearly 21 feet gauge, is a trussed structure Its principal peculiarity consists in the fact that the members of the several trusses composing it are wooden trunks or boxes about 4" square in cross sections, made of ⅜" deal, and put together with screws and shellac varnish. At the joints formed by the intersection of the various members of the trusses, the sides of the boxes are made to overlap one another over a large area, providing a large surface for screwing and for the adhesion of the shellac varnish The dimensions of the boxes forming the several members of the girders are designed so as to bring the sides of the boxes into the right planes to suit these overlaps The whole structure thus provided is remarkably rigid and light The general design of the carriage is arranged so as to leave clear a sort of central alley provided with a railway, the rails of which are close to the sides

of the alley The object of this secondary railway is to carry the smaller carriages, on which are mounted the actual experimental apparatus of different kinds, so that these may be adjusted on this railway to any desired position fore and aft on the main carriage The carriage is driven by means of wire rope from a stationary 10" Tower spherical engine, a high power being required so as to start the truck quickly for high speed experiments. The ordinary speeds range between 100 and 500 feet per minute, for some classes of models experiments are occasionally made up to about 850 feet per minute or nine and a half miles per hour The truck has been run at over 1200 feet per minute, or about fourteen miles per hour The governor, by which the speed of the engine is regulated, is a very interesting and ingenious piece of mechanism, which has been modified from the design of that which was used on the engine at Torquay There are two symmetrical bell cranks carrying weights, and attached to each other by links, having slotted holes so as to allow the bell cranks to have a very small range of freedom of angular motion. When a given speed of rotation is reached, the centrifugal force of the weights overcomes the tension of a spiral spring, provided for the purpose, and the governing action is brought into play in the following manner —There is a hooked rod, by means of which the increase in the angular altitude of the weights (due to centrifugal force) brings a friction disc break into play, which in turn has the effect of extending a spiral spring connected with the engine throttle valve, which is thus closed so as to shut off steam. It will be easily seen how much more delicate an adjustment this device gives than the old Watt governor with the balls acting directly on the valve The extension of the spring, and the consequent distance of departure of the throttle valve from its full open position are proportional to the frictional turning movement applied to the stationary wheel, which movement is itself proportional to the pressure brought to bear upon it by the bell-cranks, in other words it is proportional to the excess of the speed above that at which the centrifugal force of the weights just equals the tension of the spiral spring To give greater sensitiveness of action the bell cranks are not hung on pin joints but on flat springs after the fashion of a clock pendulum, safeguards being provided in case of the springs breaking With the Torquay governor, which was similar in principle to that described, although differing in appearance, the adjustment was so delicate that a variation of speed in the running of the carriage of half a foot per minute was seldom exceeded even at the highest speeds The value of working against the resistance of spiral springs will be noticed in this mechanism, their steadying action being especially valuable It would be impossible for us to attempt to describe the mechanism constituting the copying apparatus of the model shaping machine, and we can only hope to give a mere outline of the general principles A rough hollow model of the ship to be constructed is cast in paraffine wax, a material which is found to lend itself most perfectly to the necessities of the experiments The drawing from which the operator has to work is stretched on a table, and the grooves representing the water lines are copied from the drawing by means of the mechanism These grooves are formed by a pair of revolving cutters, the fore and aft motion being communicated to the model whilst the cutters move laterally One cutter is on each side—for of course full models are required—and they approach or recede symmetrically in such accordance with the longitudinal travel of the model as to trace in plan upon it the intended horizontal section This due accordance of the lateral motion of the cutters with the longitudinal motion of the model is accomplished by the operator so regulating the cutter motion as to maintain a tracer in contact with the corresponding water line on the drawing. By suitable mechanism the drawing itself is made to imitate the longitudinal travel of the model, while the tracer imitates the lateral travel of the cutters. In the Torquay machine the tracer was guided by an adjustable template set to the curve of each water-line, but afterwards the tracer was made to follow the line on the drawing by the operator In the present machine the cutters are raised or lowered to get the different water-lines. The cutters run at 2700 revolutions per minute. The grooves having been cut, the surplus material is removed by hand

We shall not follow Mr Froude in his description of the further details of the mechanism, as it would be unintelligible without the drawings by which he illustrated his description. The various arrangements are, however, fully worthy of study by all who are interested in ingenious mechanical devices, but we must refer our readers to the printed transactions of the institution, in which the diagrams will appear when the volume is published. There is also a weighing machine, which is necessary to obtain the actual dead weight of the model, so that the amount of ballast required to get the necessary displacement corresponding to trial draught may be determined This machine will weigh up to 1000 lbs with great accuracy, and is similar in principle to an ordinary chemical balance, except that it is a steel yard, having one arm 6 inches and the other 5 feet in length.

The discussion on this paper was opened by Mr W H White, the Director of Naval Construction, who is the official head of the Admiralty department, of which the Haslar establishment forms a branch Mr. White spoke of the advantage these model experiments had been to the navy, saying that the great advance in the speed of ships which had been obtained of late years would not have been reached to the full extent had it not been for the model experiments carried out at Torquay and Haslar by the late Mr Froude and his son, the author of the paper. Mr J I Thornycroft also pointed out the great economy that had been made in expenditure upon navy ships by finding out beforehand what the proposed vessel would do, and what was required in the way of power to reach that performance Mr Thornycroft made especial reference to the ingenuity of the device whereby a line on the drawing, which might not be quite accurate, would be made to give the desired result in the model, and this without an expensively constructed apparatus Various other speakers having been heard, and Mr Froude having briefly replied, so far as there was anything to reply to, the meeting adjourned until the next evening

On the members assembling on Friday evening, the 3rd inst, the president, Dr Anderson, again occupied the chair, and Mr Matthews's paper on the Southampton waterworks was read This contribution is interesting, as it describes what we understand is the largest water softening plant yet installed The quantity of water that can be satisfactorily dealt with is from 2¼ to 2½ million gallons per day of 24 hours Of course the principle of softening hard water by lime is very far from new, but it has made slow progress, in spite of the vast quantities of hard water, otherwise unobjectionable, that there are in the chalky southern half of our island This limited application of a means whereby a bad water in one respect can be made a good one in all respects does not appear, to judge by the proceedings of last Friday, to spring from any inherent defect in the system—beyond that which would arise from the disposal of the refuse lime in crowded cities—but rather from the carelessness of public authorities and water supplying companies to the wants and comforts of the people at large

The meeting terminated with the usual votes of thanks, the President announcing that the summer meeting would be held this year at Middlesborough on Tuesday, August 1, and the following days

THE SEVEN IMAGES OF THE HUMAN EYE

IT is well known that in the human eye, besides the refracted image, which serves the purposes of vision, there are formed three reflected images known under the name of "Purkinje's images" M Tcherning has discovered three additional ones, so that the total number is brought up to seven [1]

In its passage into the interior of the eye each ray of light has to pass through the cornea, the aqueous humour, the crystalline lens, and the vitreous humour before finally arriving at the retina. At the surface of each of these constituents the ray is liable to be partially reflected, thus giving rise to four reflected images. These were all seen and described by Purkinje at the beginning of the century, but only three were observed by Helmholtz and others These three can be easily observed by two persons on holding a lighted match between their eyes, and moving it about so that the reflections seem to come from the pupil. One of them, that reflected by the front of the cornea, is much brighter than the two others, which are formed by the front surfaces of the crystalline and the vitreous humour respectively The fourth image is due to reflection from the posterior surface of the cornea It may be discovered by careful observation of the brightest image by means of a magnifying glass. As

[1] See *Séances de la Société Française de Physique*, Avril-Novembre, 1892

it approaches the border of the pupil, and especially as it passes on to the iris, it is seen to be accompanied by a small, pale, but well-defined image, which always lies between the first image and the centre of the pupil, the distance between them decreasing as they move towards the centre, where they finally coincide By means of the ophthalmophakometer—an instrument consisting of three incandescent lamps and a telescope arranged on an arc of 86 cm radius—it was found possible to measure the radii of curvature of all the reflecting surfaces The foci of the two reflecting surfaces of the cornea were found to coincide, a fact which accounts for the coincidence of the two corresponding images at the centre of the pupil, and for Helmholtz's failure of finding the fainter one

It is evident that since the light reflected from the successive surfaces does not fall upon the retina, it is lost for visual purposes But a comparison of the percentages of loss in the case of the eye, and in that of a simple lens tells greatly in favour of the former as an optical instrument In the eye the percentage of useful light is 97, in a simple lens 92, and in a compound optical instrument correspondingly less But the light reflected by any of the internal surfaces is also liable to be reflected back into the eye or the optical instrument, with the effect of superimposing a more or less faint patch of light upon the image on the retina This is termed the noxious light (*lumière nuisible*) by M Tcherning In a simple lens this amounts to ⅓ per cent, whilst in the eye it is as low as 0·002 per cent But faint as it is, it is capable of giving rise to two light impressions due to double reflection, one at least of which has been actually observed in the human eye "The easiest way of observing it," says M Tcherning, "is to look straight forwards in a dark room, holding a lighted candle in the hand about 20 cm from the line of vision On moving the candle gently from side to side a pale image of the flame is seen on the opposite side of the line of vision, distinct enough to show that it is inverted, it moves symmetrically to the candle with respect to the line of vision The rays which form this image have undergone, besides several refractions, two reflections, one at the posterior surface of the crystalline and another at the front surface of the cornea" Another image was expected to be formed by a similar reflection at the anterior surface of the crystalline It was found in an artificial eye, but not in the human sense-organ However, an easy calculation of the optical system of the eye explains this circumstance The focus of the reflected rays is very near the crystalline lens itself, so that they must be much dispersed by the time they reach the retina To enable the image to be formed on the retina, the object would have to lie between the cornea and the crystalline, but on attempting to form a luminous point at that place by optical means it is found that the "useful rays" fill the eye to such an extent as to render everything else invisible

It is found that different eyes differ in their capacity of seeing the first of the two additional subjective images Short-sighted people find it very indistinct unless the candle is held close to the eye, or convex glasses are used As the maker of optical instruments utilises the accessory images for testing the degree of polish and the accurate centreing of the lenses, so the physician is enabled to make valuable inferences from them as to the structure and condition of the eye he is examining, and the additional images discovered by M Tcherning appear to be of considerable physiological importance E E F d'A

A BOTANIST'S VACATION IN THE HAWAIIAN ISLANDS

SOME weeks ago we reprinted from the *Botanical Gazette* (Indiana) a part of the first instalment of Prof. D H Campbell's interesting account of his vacation in the Hawaiian Islands. The following is the chief portion of the second and concluding instalment, published in the January number —

Beside visiting the isle of Oahu, I made short trips to the islands of Hawaii and Kauai. The former, the largest of the group, and the only one where volcanic action is still going on, is reached by steamer in about thirty-six hours from Honolulu. On the way, the islands of Molokai, Lanai, and Maui are passed. The first, a barren-looking and forbidding spot, is the location of the leper settlement, to which all persons afflicted with leprosy are sent as soon as their condition becomes known.

Maui, the largest of the islands next to Hawaii, consists of two portions connected by a narrow isthmus The whole eastern half is nothing more nor less than the body of an immense extinct volcano, ten thousand feet high, and with a crater nearly ten miles across The other end of the island is an older formation This island is said to be very interesting botanically, but, unfortunately, my time did not permit me to visit it.

Very soon after sighting Maui, the three great mountain masses of Hawaii began to loom up The day was clear, and the whole formation of the island became visible It consists of three great volcanic cones, of which only one is now active The highest summit, Mauna Kea, is nearly 14,000 feet above the level of the sea; the next, Mauna Loa, lacks but a few hundred feet of this, yet so great is the breadth of these masses that one fails to realise their immense height Our first landing was at Mahukona, on the leeward side of the island, a most forlorn expanse of bare lava with scarcely a trace of vegetation, except a few unhappy-looking algaroba trees planted about the straggling buildings that constituted the hamlet

We lay all day at this inhospitable station, not getting away until evening A beautiful sunset and a fine glimpse of the peak of Mauna Kea glowing with the last rays of the sun, form my most pleasant recollections of this desolate place

What a change the next morning! On awakening we found ourselves entering the harbour of Hilo Here everything is as green as can be imagined, and luxuriant vegetation comes down to the very ocean's edge The town is built on a bay fringed with cocoa-nut trees and embowered in a wealth of tropical vegetation Owing to the great annual rainfall (about 180 inches), as well as to the fact that Hawaii is the most southerly of the islands, the vegetation here is the most luxuriant and tropical found in the whole group I remained in Hilo for six days and collected some most interesting specimens Through the kindness of Mr. Hitchcock of Hilo, I was enabled to spend the night at his camp in the woods near the town, and the greater part of two days collecting in the vicinity The forest here is most interesting Mr Hitchcock was starting a coffee plantation and has cut trails through the woods in several directions, so that collecting was very convenient There is great danger of losing one's self in these woods where there are no trails, as much of the forest is an almost impassable jungle In these moist forests ferns and mosses luxuriate, and every trunk and log is closely draped with those beautiful growths Flowers are almost entirely wanting, a fact repeatedly observed by collectors in tropical forests I saw here fully developed specimens of tree-ferns The finest of these were species of Cibotium Many had trunks from fifteen to twenty feet high, and some must have been fully thirty The most beautiful were some with trunks ten to fifteen feet high, as these were more symmetrical and had finer fronds than the taller ones. I measured the leaves of one that had fallen over, and roughly estimated the length as eighteen feet. I have no doubt that specimens fully twenty feet long could be found These giant fronds, arching high over one's head as one rides on horseback under them, present a sight at once unique and beautiful Growing upon the trunks of these ferns were many epiphytic species, the most peculiar of which was *Ophioglossum pendulum*, with long strap-shaped leaves, a foot or two long, and a spike of sporangia sometimes six inches long Exquisite species of Hymenophyllum and Trichomanes, the most ethereal of all the fern tribes, with almost transparent, filmy leaves, were common, sometimes completely enveloping the trunks of the trees Of the terrestrial ferns, which abounded everywhere, two were especially notable as representing groups unknown in the United States. One of these, *Gleichenia dichotoma*, forms extensive thickets on the borders of the forest, and in the Hilo district extends down almost to the sea-level. The other, *Marattia Douglasii*, a very large fern with leaves eight to ten feet long in well grown specimens, has fleshy dark green leaves, and thick stipules sheathing the base of the leaf stalks. Several species of Lycopodium and Selaginella were common, and a good variety of mosses and liverworts. In these forests wild bananas are common, and most magnificent plants they are Sheltered from the wind, the superb great leaves develop to their full size, without being torn in the least, and the whole plant is a study of beautiful form and colour

Coffee is being extensively planted in this region as well as upon the lee side of the island, and as the quality of the berry

is exceptionally fine, this promises soon to be a leading industry in the islands.

About Hilo especially, but common also elsewhere, was a very conspicuous black fungus, that covered the leaves completely in many cases, and attacked indiscriminately a great variety of trees

From Hilo I proceeded to the volcano of Kilauea, some thirty miles distant, and about 4000 feet above the level of the sea As this volcano has so often been the theme of travellers' descriptions I will not linger over it In the vicinity are many interesting plants, among them a species of Vaccinium with sub acid yellow and red berries something like cranberries These "ohelo" berries are much esteemed, and are especially good when cooked Some two miles from the volcano is a superb grove of koa trees, the largest trees I saw anywhere in the islands One of these standing alone, and with magnificent spread of branches, must have been ten feet in diameter The road to the volcano lies for much of the way through a fine forest In the lower part the ohia trees were loaded with their beautiful crimson fruit, and present a very showy appearance Of flowers, the species of Ipomæa were the most conspicuous, but the scarlet flower-bracts of Freycinetia were conspicuous at times, for here this latter plant may often be seen running to the tops of the tallest trees

The glory of this road, however, is *the tree-ferns*, which all along excite one's admiration The carriage road is not yet completed, and about thirteen miles must be done on horseback Of this more than a mile is over a corduroy road made out of the trunks of ferns! Such a road, if not very durable, is yet very pleasant to horses As these trunks lay prostrate, in the damp atmosphere, most of them were already sending out new fronds, and in due course of time the road will be fringed with a hedge of great fern-leaves Indeed, in some of the more open parts of the road farther down, where the ground is completely occupied by a small tree-fern growing in dense thickets, as these are grubbed out to make way for cultivation, their trunks are piled up to form fences, and soon sprout out so that they make a beautiful and close hedge of fern-leaves

On leaving the volcano I went down on the other side of the island The rain being almost entirely intercepted by the mountains, this leeward side is very dry, and the ride to Punaluu, where we were to take the steamer, was not especially pleasant Vegetation is very scanty, and nothing particularly interesting was noted in this line. The soil on this side of the island, especially in the district of Kona, is very fertile, and when water can be had, produces magnificent crops of all the tropical staples, pine apples, cocoa nuts, coffee, sugar, &c, all especially fine, and we feasted on these cocoa nuts and pine-apples as we sailed along this picturesque, if somewhat barren, coast

A short, flying trip was made to the Island of Kauai, the richest botanically of all the islands, as it is the oldest geologically According to Hillebrand, not only is the number of species larger than in the other islands, but the species are more specialised Here I saw several species of the curious woody Lobeliaceæ, of which there are several genera that form either shrubs or small trees I saw several species of Cyanea, with stems six to eight feet high, with long leaves crowded at the top of the stem and many white or purplish flowers, much like those of Lobelia, but somewhat larger and less open

As in all the islands, there is on Kauai a great difference between the windward and leeward sides I drove for about thirty miles along the windward side of this island through some of the most beautiful scenery of all the islands. Near the sea were rolling plains and hills, with here and there groves of Pandanus and Hau—the latter a dense spreading small tree with large yellow hibiscus flowers—and at one point we drove through a magnificent grove of kukui trees, the finest I saw anywhere As we reached that part of the island which is most fully exposed to the moisture-laden trade-winds, vegetation became extremely luxuriant. Numerous valleys with clear streams flowing down them, their bottoms given up to rice plantations, were to be seen here, with the rice in all stages, from the young spears just standing above the water to golden-yellow patches of ripe grain At Hanalei, my destination, I found excellent accommodation and a delightful bathing beach, the latter especially attractive after a thirty-five mile drive over dusty roads Hanalei is beautifully situated on a picturesque bay, with bold mountains rising directly back The next morning a native was hired to go with me into the woods, and the day was spent in collecting. The variety of trees, as well as other phænogams, is much greater here than in Hawaii, the ferns, also, were very fine. Here I obtained a prize in a fine lot of the prothallia and young plants of Marattia, as well as some other interesting things

Want of space forbids going into details, but no botanist visiting the islands can afford to miss Kauai

In position, the Hawaiian Islands are unique, being more isolated than any other land of equal area upon the globe More than 2000 miles separates them from the mainland, and 1860 miles from the nearest high islands Of purely volcanic origin, thrown up from an immense depth, they have always been thus isolated As might be expected, the flora is very peculiar, more so than in any other country According to Hillebrand, of 800 species of spermaphytes and pteridophytes that are strictly indigenous, 653, or 75 per cent, are endemic. Taking out the pteridophytes, the spermaphytes show over 81 per cent, and the dicotyledons over 85 per cent that are found only in this group

For a thorough study of this very curious flora, a long time would be necessary, as many species are extraordinarily local, and many of the most interesting localities are very difficult of access The islands differ extremely among themselves, and exhibit in a most interesting manner the correspondence that exists between the variety and differentiation of forms and the ages of the islands The formation of the islands has proceeded from north to south, and Kauai, the northernmost of the large islands of the group, is also the oldest and much the richest botanically, especially as regards spermaphytes, and, according to Hillebrand, the genera and species are more differentiated Hawaii, the southernmost of the islands, is much the poorest in forms, although in the Hilo district the conditions are most favourable for a luxuriant development of forms.

In the latter island is the last active volcano of the group, Mauna Loa, with its two craters, of which the well-known crater of Kilauea is the great sight of the islands, and visited constantly by tourists from all parts of the world

A few days after my return to Honolulu from Kauai, and six weeks from my first arrival there, I boarded the *Monowai*, the through Australian steamer bound for San Francisco, which was reached in due season after an uneventful passage And so ended my first trip to the tropics

INSTRUMENTS FOR THE EARTHQUAKE LABORATORY AT THE CHICAGO EXPOSITION

THE first earthquake instrument ever invented, a drawing of which is shown on the wall, is in all probability that of Chōkō, dating from the year A D 132 The first instrument used for keeping systematic records in Japan was Palmieri's modification of the contrivance sketched out by the late Robert Mallet Since this not only have all forms of seismographs and seismoscopes employed in Europe and America been employed, but many special forms have been designed in Japan, with the result that rather than Japan borrowing from Europe and America, these countries are using inventions which had their origin in Japan A few of these instruments are exhibited in this laboratory. The main feature in their construction is that they all work from "*steady points*," and for small earthquakes at least, we can say with confidence that the diagrams they yield are absolute measurements of the earth's motion From diagrams written on stationary plates we know the extent and the direction of the principal vibrations in a shock, but when the movements are recorded on a moving surface, we know the period or the rapidity with which the movements follow each other. From these latter diagrams the acceleration or suddenness of movements may be calculated, and the factors given to engineers enabling them to construct to resist known forces, rather than simply building strongly because an earthquake is strong

INSTRUMENTS EXHIBITED

1 *Seismograph writing on a glass disc* —Here we have horizontal pendulums writing the earth's motion as two rectangular components on the surface of a smoked glass plate. The vertical motion is given by a vertical spring lever seismograph The rate at which the plate revolves is accurately marked by an electrical time ticker. The movements of the latter are governed by a pendulum swinging across and making contacts with a small vessel of mercury.;

The revolving plate is kept in motion by clockwork, which is set in motion by an electric seismoscope (See No 8)

2 *Seismograph writing on a drum*—In this instrument the record is written on a band of paper, the diagram being less difficult to interpret because it is written to the right and left of a straight line and not round a circle

3 *Seismograph writing on a band of paper*—In this instrument not only is the diagram written along a straight line but it is written with pencil,—the trouble of handling smoked paper being therefore avoided When the earthquake ceases, the drum ceases to revolve, but if a second or third earthquake should occur, it is again set in motion By this means a series of earthquakes may be recorded, the resetting of the instrument being automatic

4 *Seismograph without multiplying levers*—This instrument is intended to record large motions, the horizontal levers not being prolonged beyond the steady points to multiply the motion For large earthquakes, when the ground is thrown into wave like undulations, special instruments which measure tilting are employed

5 *Duplex pendulum seismograph.*—In this case a steady point is obtained by controlling the motion of an ordinary pendulum with an inverted pendulum The record consists of a series of superimposed curves written on a smoked glass plate

6 *Mantelpiece seismometer*—This is intended for the use of those who simply wish to know the direction and extent of motion as recorded at their own house It is a form of duplex pendulum, and it gives absolute measurements for small displacements

7 *Tromometer.*—This is one form of an instrument which is used to record movements which are common to all countries, called earth tremors Every five minutes, by clockwork contacts and an induction coil, sparks are discharged from the end of the long pointer to perforate the bands of paper which are slowly moving across the brass table If the pointer is at rest, then a series of holes are made following each other in a straight line, but if it is moving, the bands of paper are perforated in all directions round what would be the normal line of perforations

The earth movements which cause these disturbances are apparently long surface undulations of the earth's crust, in form not unlike the swell upon the ocean

A more satisfactory method of recording these motions, which has been used for the last two years, is by a continuous photograph of a ray of light reflected from a small mirror attached to a small but extremely light horizontal pendulum

8 *Electrical contact maker*—These instruments are delicate seismoscopes, which on the slightest disturbance close an electric circuit, which, actuating electric magnets, set free the machinery driving the recording surfaces on which diagrams are written.

9. *Clock*—At the time of an earthquake the dial of this clock moves quickly back and forth and receives on its surface three dots from the inkpads on its fingers. It thus records hours, minutes, and seconds, without being stopped

10. *Model of an earthquake*—The bent wires represent the path traced by an earth particle at the time of the earthquake of January 15, 1887 The numbers indicate successive seconds This model was made by Prof S Sekiya.

11. *Safety lamps.*—These are lamps which if overturned are at once extinguished. One of these is a European invention and the other Japanese.

12. *Pictures*—The pictures on the walls show the effects of the Great Earthquake of October 28, 1891, the devastation following the Eruption of Bandaisan in 1887, and several of the more important volcanoes in Japan. They were made by Prof. W K. Burton.

JOHN MILNE, F OMORI
Seismological Laboratory, Imperial University of Japan, Tokio.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Last Term the Board of Faculty of Natural Science recommended that an honour examination in Natural Science should be instituted, bearing the same relation to the Final School that Moderations bear to the Final School of Literae Humaniores. The recommendation of the Board was not unanimous, and on the matter coming before the Hebdomadal Council last week, it was put aside on the ground of want of unanimity among the various scientific departments There was much to be said both for and against the proposed examination It would probably have raised the standard of the chemical and physical work done by biologists, but would have forced an additional subject on the chemists and physicists, which they were very unwilling to assent to

CAMBRIDGE.—The Adams Prize has been awarded to Prof J H Poynting, F R S., late Fellow of Trinity College, for a memoir on the methods of determining the absolute and relative value of gravitation and the mean density of the earth

The Professor of Pathology (Mr Roy) gives notice that on Thursday, February 9, a lecture and demonstration will be given by Dr Hafkine, of the Pasteur Institute, on his method of conferring immunity against Asiatic cholera The lecture will be delivered at the Pathological Laboratory at 4 30, and will be open to members of the University

The office of Esquire Bedell has been rendered vacant by the death of Mr F C. Wace, a distinguished mathematician, formerly Fellow and Lecturer in Mathematics at St John's College, and thrice elected Mayor of the Borough of Cambridge

SCIENTIFIC SERIALS

Wiedemann's Annalen der Physik und Chemie, No 1—Essay towards an extension of Maxwell's Theory, by Hermann Ebert The author obtains expressions for dispersion and absorption of waves of the order of light-waves analogous to those obtained by Goldhammer, and shows that they may be derived from Maxwell's fundamental conceptions by applying them to the case of rapidly changing displacements.—A new kind of magnetic and electric measuring apparatus, by G Quincke. These are made of glass, ebonite, and wood No screws are used in their construction, and they are claimed to cost a tenth of the price of ordinary instruments, with equal accuracy In each of them the needles are suspended at the hollow centre of a vertical circular glass disc—On a null method for measuring the dielectric constants of conducting liquids, by Friedrich Heerwagen—On a phenomenon analogous to Newton's rings observed during the passage of Hertz electric plane waves through plane parallel metal plates, by Ludwig Boltzmann The author removes an apparent contradiction between Maxwell's theory and Hertz's observation that even excessively thin metal plates do not transmit electric waves a few decimetres long, by showing that this is not due to absorption, but to the limiting conditions at the surfaces of separation deducible from Maxwell's formulæ—On a medium whose mechanical properties lead to the equations propounded by Maxwell for electromagnetism, by L. Boltzmann—On some questions concerning Maxwell's theory of electricity, by L Boltzmann—The index of refraction of electric rays in alcohol, by H O G Ellinger—On the electrification of air in glow and brush discharges, by Ad. Heydweiler.—On the calculation of magneto optic phenomena, by P. Drude.—Spectra of aluminium, indium, and thallium, by H Kayser and C Runge—On the infra-red spectra of the alkalies, by H Kayser and C Runge. A criticism of Benjamin Snow's work on the same subject—Investigations concerning interior conduction of heat, by Richard Wachsmuth.—On the absolute value of the thermal conductivity of air, by A. Winkelmann—On a modification of the transpiration method suitable for the investigation of very viscous liquids, by C Brodmann The substance was made to pass from a funnel-shaped reservoir through a capillary tube into a beaker standing on one pan of a chemical balance. The time was noted at which the amount of liquid passed into the beaker was large enough to overcome the counterpoise in the other pan, and to disturb the equilibrium, and further small weights were added and similarly dealt with. The temperature was kept constant by a spiral water-pipe and felt jacket, and local differences and variations of level and buoyancy were corrected for The liquid experimented upon was glycerine, and the temperature curves were hyperbolas.—Notes on M Cantor's thesis on capillary constants, by Th. Lohnstein—Note on the purification of mercury, by W. Jaeger

Notes from the Leyden Museum—Of volume xiv numbers 1 and 2 were published in April, and numbers 3 and 4 in July last Edited by Dr. F. A. Jentink, this volume contains 282 pages and ten plates. The notes on Mammals are, by the editor on *Semnopithecus pyrrhus*, Horsfield, and on *Pithecia melanurus*, S. Muller (Pls. 3 and 4) In volume xii. Dr Jentink,

p. 222, gave a note about this latter very rare, nearly forgotten, and often misunderstood little rodent, figured by Alfred Duvaucel in F Cuvier's great work, the "Histoire Naturelle des Mammiferes." Cuvier could give no indication of its size, nor of its native country, guessing that "qu'il est originaire des provinces du Nord de Bengale, si ce n'est des parties occidentales de Sumatra." Dr S Muller, in 1834, obtained a specimen in Java, to the northern side of Mount Gede, and named the species This, and another specimen from Sumatra (also collected by Muller) are both in the Leyden Museum as stuffed specimens The skulls of these two specimens were detected in the Leyden Museum by Oldfield Thomas, and were included by Jentink in his catalogue of 1887, though with a query But all doubt on the subject was removed at the date of this paper, and now the animal has been taken alive by Mr J. D Pasteur on the northern slope of the Goenong Gedeh, Java, an account of which capture is given in a very graphic translation of a letter to Dr Jentink On birds there are papers by J Buttikofer on the specimens of the genus Tatare in the Museum, on the specific value of Levaillant's "Traquet Commandeur," and on the collections of birds sent by the late A T Demery from the Sulymah river, West Africa, pp 13-30 In this last paper 96 species are recorded, ten of which are new to Liberia, on *Batrachostomus poliolophus*, n sp from W Sumatra, by Ernst Hartert, on a weaver finch from Sumatra, and on a collection of birds from the islands of Flores, Sumba, and Rotti, by J Buttikofer, and on the birds of Sumba, by A H Meyer About fish there is a note by Dr Th W van Lidth de Jeude on *Orthragoriscus nasus*, Ranzani, which had been washed ashore in November, 1891, at Callantsoog A figure from a photograph is given — M Schepman describes a number of land and fresh water mollusca from Soemba, Timor, and other East Indian islands, several new species are diagnosed —Dr J G de Man continues his Carcinological studies in the Leyden Museum, and in No 6 describes several new species which are figured A very important contribution to our knowledge of the echinoderms is made by Dr Clemens Hartlaub's paper on the species and structure of the hard parts in Culcita; nine species are carefully described, their geographical distribution is given, *Culcita grex*, M T, is figured from a photograph, and a fairly complete bibliography is appended. The rest of the papers are descriptions of new forms of insects.

No 1 of vol. xv, dated as January, 1893, but published October 30 last, contains a review of the genus Rhipidura, with an enumeration of the specimens in the Leyden Museum A key to the 75 species now known is given—five are described for the first time M E Buchner has a note on the occurrence of *Mellivora indica*, Kerr, in the Trans Caspian district, on two supposed new species of Pentadactylus, by M Schepman There are also several papers on new forms of insects

SOCIETIES AND ACADEMIES.

LONDON

Royal Society, January 26 —"On the Three Bar Motion of Watt" By William Brennand Communicated by C B Clarke, F R S

"Further Researches in Connection with the Metallurgy of Bismuth" By Edward Matthey, F S A., F C.S, Assoc Roy Sch Mines Communicated by Sir G G. Stokes, Bart, F.R S

Paper IV —"Bismuth, its Separation from Arsenic"—In melting large quantities of bismuth containing arsenic it was found that the surface of the metal being exposed to the air arsenical fumes appeared, and that as the temperature of the metal was raised the arsenic came off in dense white fumes (As_2O_3) An alloy of bismuth containing 0 65 per cent of arsenic was carefully operated upon and freed from the whole of its arsenical contents, the temperatures being noted at which the separation takes place. When raised to a temperature of 513°C and maintained at this for a short period, the bismuth was found to be absolutely free from arsenic.

Paper V "Bismuth, its Separation from Antimony"—Whilst engaged in fusing some 400 or 500 kilogrammes of bismuth containing antimony it was noticed that a peculiar oily film formed on the surface of the alloy, which on being removed and tested was found to contain a considerable percentage of antimony. By continuing the operation and removing the film from time to time as it formed, the melted metal became bright, and was then found to be perfectly free from antimony. A quantity of about 350 kilogrammes of bismuth containing 0 80 per cent of antimony was melted and the temperature observed at which the antimony separated as described By maintaining a constant temperature of 458° C. the whole of the antimony separated, leaving the bismuth free from any trace of this metal The temperatures were determined by the pyrometer of M. H le Chatelier

Physical Society, January 13 —Prof G F Fitzgerald, F R S, President, in the chair —Mr F W Sanderson read a paper on science teaching In this communication the author considers the methods of teaching physical science, and remarks that other sciences may best be treated in some different manner. The method recommended is one found suitable in public schools where boys may remain till about the age of nineteen In elementary and secondary schools modification would be necessary with a view to making it more immediately useful, whilst in university and technical colleges other methods might be preferable The object of his public school method was to make physical science a definite means of education, rather than to produce skilled physicists Certain mathematical subjects, such as arithmetic, geometry, and algebra, should be taught before physics is begun, and taught in such a way as to aid subsequent physical work In teaching arithmetic it is deemed desirable to distinguish between the science and the art of it, and to have separate hours for instruction in each The subjects included in each part are described in some detail in the paper No existing arithmetic satisfies the author's requirements Geometry is considered of the first importance, practical geometry and the use of instruments forming the best introduction to the subject It is recommended that the elementary part be taught by the mathematical master with a view to formal geometry, *e g* Euclid As most practical geometries consist of isolated constructions they are useless for teaching the subject in a scientific manner A number of problems suitable for a graduated introductory course are given After elementary geometry, mensuration may be taken up with advantage, the facts being verified by drawing to scale, measuring, or by weighing, but no rules being given Trigonometry of one angle may then be commenced Here also free use should be made of the drawing board, each pupil finding the sines, cosines, and tangents of angles by drawing and measurement, and making tables Quite independent of the mathematical class the author has been in the habit of carrying boys on the engineering side through a course of graphical analytical geometry, in which they draw straight lines and the quadratic curves, &c., from their equations, solve simultaneous linear equations, quadratics, cubics, &c Other geometrical constructions follow The subject as to what branches of science should be taught in the different departments of a school is then considered, and schemes are given for the classical, modern and commercial, science, and engineering sides Some general principles which have been kept in view in arranging the physical teaching are next described In the first place the fundamental experiments and observations on which each scientific law is based are explained to the pupils, and when possible the experiments are performed by the boys in the laboratory Secondly, from the experiments the laws are stated as precisely as possible, the form of statement depending on the knowledge possessed by the class. The problem of expressing a law mathematically from its most fundamental statement is then fully considered Thirdly, mathematical deductions from the laws are followed out, and the pupils perform experiments to verify the results, and thus confirm the laws Fourthly, a course of exact physical measurements is given, which includes mensuration, hydrostatics, mechanics, sound, heat, electricity, and light. A first and second year's course is arranged in each subject, and in both years all the boys work the same experiment at the same time This necessitates multiplication of apparatus, but being of a simple character in the lower forms where the pupils are numerous it is not prohibitive. It is also stated that boys get better results with comparatively rough apparatus, if large, than with delicate and expensive instruments About half the time devoted to physics is spent in the laboratory Mathematics is introduced, as far as can be done without straining the pupils too much, and with young classes appeal is made to experiment where the strictly logical argument would be difficult to follow. Instead of teaching the applications of science as done in some technical schools, the author's method is to teach pure science, and let the applications come in as

illustrations. At the end of the paper detailed lists of experiments for practical courses in electricity and optics are given Samples of the apparatus used were exhibited at the meeting, those for optics being particularly simple and ingenious — Prof A. M Worthington said his experience led him to a very hearty agreement with Mr. Sanderson on all essential points, and he thought there was now a close agreement amongst teachers as to the best methods. He therefore wished to ask, Had not the time now come at which the Physical Society might usefully endeavour to exert direct influence on science teaching? As the scientific instruction of a person who intends following a scientific calling is generally divided into stages, and conducted in different places under different teachers, he thought it was desirable that those in charge of his training at each stage should say up to what point his instruction should be carried before he reaches them Other matters in which the society might do useful work were (1) reporting on text-books and condemning the bad ones, and (2) furthering the adoption of the decimal system. At present, he said, an enormous extension in the teaching of physical science is taking place, and it seemed within the power of the Physical Society to place itself at the head of the movement Another point which required to be settled was the relative importance of physics and chemistry at different stages of a student's education —Mr. L. Cumming agreed with the general principles laid down by Mr Sanderson In attempting to carry out such schemes numerous difficulties presented themselves, especially where the science master had not control over the subdivision of the boys' time He had tried teaching the science of arithmetic to boys in the lower forms, but the results were not encouraging, for he found very few who could do much in it They seemed to devote themselves much more readily to concrete problems and the art of manipulation of rules Graphical statics was very valuable. As regards experimental lectures, he believed them to be very important, especially in junior classes For scholarship boys a different method had been tried with success. Instead of performing lengthy experiments completely before the class, the essential parts were gone over, and for the minor points the results obtained in experiments made before or after the lecture were given, so that all the data for reducing the results were to hand This saved considerable time He had hoped Mr Sanderson would say something about the slide rule, and wished to learn his opinions on its use —Dr Stoney said he was very much struck with the methods of teaching brought forward by Mr Sanderson, and remarked that his own work would have been considerably lightened if such a scheme had been developed many years ago Experimental methods were very valuable, provided the inaccuracies of measurement be kept in view. Plotting curves was also very instructive, and might be made a means of furnishing the fundamental notions in the differential and integral calculus As to the introduction of chemistry, his experience went to show that this should be done at an early age Dynamics should also be begun early.—Mr. W B Croft thought that if the Society did make rules to regulate the teaching of physical science, these rules should not be too strict, for the ages and aims of boys might differ widely. At Winchester the science teaching was carried out on the lines recommended by a committee of the Royal Society appointed to consider the subject (Leaflets showing the scheme adopted were here distributed to members.) The object of the scheme was not merely to make science a means of education, but an integral part of the education of the pupils He also made a point of keeping the lecture experiments up to date —Mr. Rentoul said dynamics should not be taught as a mathematical subject, but experimentally. He thought it of the first importance that boys should learn how to find out facts for themselves, and for this practical work was essential. —Prof. Ayrton remarked that the conditions under which science was taught differed in different places. He himself taught with the object of enabling the persons under instruction to improve the industry For this purpose he believed the analytical method more suitable than the synthetical one advocated by Mr. Sanderson It also had the advantage of being more scientific, for it was more natural, being, in fact, that used by children from birth, for they had no other means of learning the nature and properties of their surroundings. In his first year's technical course the work was synthetical, whilst in the third year the students, having analysed existing apparatus, were taught to devise new or improved forms, and hence the work became more synthetical —Mr F J. Smith said it was important that students be taught to measure by the balance, micrometer, spherometer, and as soon as possible He also inquired how far Mr Sanderson's pupils could help themselves in making the apparatus required for the simple experiments —Dr Gladstone agreed with many points in the paper Lately he had had to do with schemes for improving the teaching in elementary schools Children were naturally philosophers, but at present their curiosity was considered objectionable and sternly repressed Efforts were now being made to alter this state of things Kindergarten classes in infant schools were a step in the right direction. It was very difficult to introduce analogous methods in the higher standards, but natural science had now obtained a footing Although the methods of teaching adopted might be those suitable for pure science, care should be taken to put in practical illustrations, for when suitably chosen they are sources of great interest to children —Mr. Sanderson, in reply, said the slide rule was used throughout the course Mechanics was taught by actual machines, such as pulley blocks, screw jacks, &c The boys made some apparatus, but to make all would require too much time —The President, when proposing a vote of thanks to the author of the paper, said that in Ireland the opinion that boys and girls cannot be taught science greatly predominated They found considerable difficulty in getting any continuation of the kindergarten teaching sanctioned. Possibly drawing might be allowed, but this seemed all they could hope for at present He wished to emphasise the fact that in such schools the object was education, and practical applications of science were not important except in so far as it created an interest in the subjects At present scientific teaching was in an experimental stage, and as in other things, progress is made by trial and error Many different methods were being tried, and it was important to know which were successful and which failures. He thought the Physical Society might be useful in collecting information on the subject by issuing a circular of questions to science teachers, and subsequently drawing up a report on the subject

Royal Microscopical Society, December 21 —Dr R Braithwaite, President, in the chair —After the formal business necessary to be done at the meeting preceding the annual meeting, the Society adjourned as a mark of respect to the lately deceased Sir Richard Owen, K C.B , the first president of the Society.

January 18 —Dr R Braithwaite, President, in the chair —This being the annual meeting the President gave an address on the development of mosses and sphagnums, illustrating his subject with drawings and slides under microscopes in the room —On the Rev Canon Carr proposing, and Mr. W T Suffolk seconding, a hearty vote of thanks was given to the President for his interesting address —The annual report and the treasurer's statement of accounts having been read and adopted, the following were elected as officers and council for the ensuing year, —President Mr. A D Michael, Vice-Presidents Dr R Braithwaite, Mr. F Crisp, Mr James Glaisher, and Prof. Charles Stewart, Treasurer Mr W. T Suffolk, Secretaries Prof F Jeffrey Bell, Dr. W. H Dallinger, Ordinary Members: Dr Lionel S. Beale, Mr A W. Bennett, Rev. Canon Carr, Mr E Dadswell, Mr C Haughton Gill, Dr R G. Hebb, Mr G C Karop, Mr. E M Nelson, Mr T. H Powell, Prof. Urban Pritchard, Mr F H Ward, and Mr. T Charters White.

OXFORD

University Junior Scientific Club, February 1.—The President in the chair —At the conclusion of private business Mr J E Marsh gave an exhibit of some products of the electric furnace He had brought for the inspection of the club some specimens, from M Moissan's laboratory, of fused lime and uranium reduced from the oxide. He explained the construction of the furnace, and the methods of using it and of obtaining the temperature of the arc. He further commented on M Berthelot's views as to the limit of temperature of the furnace, pointing out that the maximum value was that of the temperature of vaporisation of carbon, and that in all cases this was obtained. After a short discussion Mr F. Finn, who has just returned from Africa on a worm-hunting expedition, described the incidents of his journey His remarks were illustrated by a number of lantern slides showing scenes on the coast, chiefly at Mombasa and Zanzibar. His first stay was at Lamu, where he did not get any worms, the natives misunderstanding his signs and bringing bones. He described his impressions of Zanzibar at some

length, being agreeably surprised at the place Near here he obtained several reptiles and birds which are now in the Zoological Gardens His chief collection was made at Mombasa, however He speaks very highly of the hospitality of the Europeans on that coast —Mr F G Fremantle read a paper on Hermaphroditism, confining his attention to human beings He divided his subject into various classes, ranging from complete, or almost complete, neutrality of sex, to those cases where either male or female characteristics preponderated, concluding with some cases of pure deception The paper was illustrated with diagrams, and a large number of cases were cited in support of the statements made He showed that a perfect hermaphrodite both physiologically and anatomically could not exist, either the male or female characters preponderating in every case After a short discussion the club adjourned until February 17

CAMBRIDGE

Philosophical Society, January 30 —Prof T McK. Hughes, President, in the Chair —Mr Bateson exhibited a dog's skull, lent by Mr J Harrison of Northampton, in which the upper canines were bigeminous, each having two crowns both in the plane of the arcade —The following communications were made:—On a new fern from the coal measures, by Mr A C Seward The specimen described as a new species, *Rachiopteris Williamsoni*, resembles in certain particulars the genus *Myeloxylon*, but possesses distinctive characters not previously recognised in fossil fern petioles *Rachiopteris Williamsoni* may be briefly described as a petiole with scattered vascular bundles, those near the periphery appear to be rather collateral than concentric in structure, but the larger bundles have a more decided concentric arrangement of the xylem and phloem Each group of xylem elements is surrounded by a ring of small secretory canals The hypoderm is like that of *Myeloxylon*, and gum (?) canals are abundantly distributed in the ground tissue On the intestinal movements of *Daphnia*, by Mr W B Hardy — On Urobilin, by A Eichholz, Emmanuel College In this communication a new method of urobilin extraction was described, by which the pigment is preserved in the state of chromogen The properties of urobilin in normal and febrile urines were recapitulated in order to compare urobilin with the reduction products from bilirubin and hæmatin. The communication was then devoted to a description of experiments devised to settle the question as to the possibility of artificial production of urobilin from bilirubin and hæmatin. After pointing out how Maly's hydrobilirubin differs from true urobilin, and how consequently the identity of Hoppe Seyler's and Neucki and Sieber's urobilin from hæmatin reduction becomes doubtful, it was shown, in spite of statements to the contrary by McMunn and Le Nobel, that it is possible by complete reduction of both bilirubin and hæmatin to obtain substances in each case accurately resembling urobilin

PARIS

Academy of Sciences, January 30 —M de Lacaze-Duthiers in the chair —On some objects made of copper of a very ancient date, discovered in the course of M Sarzec's excavations in Chaldæa, by M Berthelot M de Sarzec has unearthed some relics of the most ancient Chaldæan civilisation, which confirm M Berthelot's views as to the existence of an age during which pure copper was used instead of bronze, the latter being introduced after the rise of the commerce in tin A fragment of a small votive figure, found among the foundations of an edifice more ancient than that of the King Our-Nina, was assayed for copper and chlorine by means of nitric acid. It contained neither silver, bismuth, tin, antimony, zinc, nor magnesium, only traces of lead, arsenic, and sulphur, and 77 7 per cent of copper, the bulk of the rest consisting of alkaline earthy carbonates and silica. Its composition resembles that of the statuette of the Chaldæan King Goudeah, and also that of the sceptre of the Egyptian King Pepi I, of the sixth dynasty, showing that in those early times tin was not known in the two most ancient homes of civilisation —On the diurnal variations of gravitation, by M Mascart A barometric tube enclosing a column of mercury 4 5m in length, balanced by the pressure of hydrogen contained in a lateral vessel, has been kept surrounded by earth for several years at the Parc Saint-Maur Observatory, only the short upper end emerging from the ground. A study of the daily motions of the column by means of photographic registration has recently, apart from the slow and steady changes due to inevitable differences of temperature, shown sudden variations lasting from 15 to 60 minutes, which can hardly be explained otherwise than as due to corresponding variations in gravitation. They have been as high as 1/20 mm, or 1/90000 The differences of sea level from high to low water would only produce 1/5th of this variation. The phenomena, if due to subterranean displacements, would be specially interesting in volcanic districts —On solar statistics for the year 1892, by M Rod. Wolf —On the pathogenic properties of the soluble substances formed by the microbe of contagious bovine peripneumonia, and their value for the diagnosis of the chronic forms of this disease, by M S Arloing —The H and K lines in the spectrum of the solar faculæ, by Mr George E Hale — On the differential equations of a higher order, the integral of which only admits of a given number of determinations, by M Paul Painlevé —On ordinary linear differential equations, by M Jules Cels.—On the systems of linear differential equations of the first order, by M. QUALITATIVE CHEMICAL ANALYSIS

Qualitative Analysis Tables and the Reactions of certain Organic Substances By E A Letts, D Sc, Ph D, F R S E., F C S, &c (Belfast Mayne and Boyd, 1892)

THE author in his preface says, "Every teacher has his own methods—acquired not only from his experience, but also largely through the researches of others—and this book embodies mine" Therefore the volume cannot fail to be welcome to those who take an interest in the teaching of analytical chemistry But it is surprising to find that Prof Letts has until quite recently followed the old method of dictating reactions and methods to his students, and allowing them to work from their own notes For the last fifteen years there has been no lack of text-books of qualitative analysis, and Prof Letts has found, what probably all teachers of the subject are aware of, that students rarely take accurate notes But, however exact they may be, every one knows that manuscript is not so easily deciphered nor so readily referred to as a printed page

The methods of work given are, of course, more or less on the ordinary lines The final test for bismuth depends upon the production of its black suboxide, and this reaction has much to recommend it, though probably many would prefer the oxychloride reaction The use of ammonium molybdate as a separative reagent in qualitative analysis we do not consider advisable for many reasons, but no complaint can be lodged against it on the score of its accuracy

There can be no doubt whatever that both Prof Letts and his students will find considerable advantage in the use of boldly-printed statements of methods But the author begins his preface by stating that although the book has been written chiefly for his own students, he will be glad if it prove of service to others also This lays the volume open to general criticism, and prompts us to complain that it is neither so clear nor so systematic as it might have been As to the want of clearness, there are a few expressions that can easily be altered in a second edition, and these we lay no particular stress upon. For example, at page 27, in the description of Bunsen's dry tests, we read:—"The charred end of the match is next moistened with fused carbonate of soda." At page 40 it states that the solution "is mixed with its own volume of chloride of ammonium" One assumes this to be a solution, but if so the strength of it is not given, and we fear that the bulk of the solution to which it is to be added will be likely to vary enormously according to the peculiarities of the student and the character of the substance he is at work upon.

The more important want of clearness may be exemplified by taking the case of a student who has Epsom salts given to him as a simple salt. This can hardly be called an out-of-the-way substance, but so far as we can discover, the student in following these tables would examine it by the following series of operations. Heating on platinum wire to see the colour of the flame. Heating on a borax bead in the outer and inner flames Heating on a carbonate of soda bead Heating on charcoal (if a white mass resulted, which with cobalt nitrate gave a "faint pink," the metal might be recognised here, but as magnesium sulphate does not readily yield this reaction in most cases the student would pass on). Heating on charcoal with sodium carbonate Heating in a glass tube closed at one end Repeating with bisulphate of potash Repeating with black flux Repeating with magnesium wire He would then dissolve the substance in water, and test a part of the solution for ammonia by heating it with caustic alkali Then heat a part on a platinum wire for the flame colouration, a test that has already been done on the solid, and then pass on to the examination of the solution in the ordinary way for the base, and finally search for the acid if it is not already found It may be taken for granted that this fiddling about with the substance is not intended, but the volume does not appear to contain directions as to how to go more directly to work

The want of system that we complain of is acknowledged by the author himself in picking out certain parts and labelling them as "systematic" If the whole were systematic this distinction would obviously be meaningless As this fault exists in many of the text-books and in much of the teaching that we have had experience of, we are tempted to make a few general remarks upon the matter without special reference to the volume under notice

That qualitative analysis is often regarded as a very unimportant branch of chemistry, may account for its comparative neglect One constantly meets with students who are able to perform quantitative operations of not too complex a character with commendable accuracy, and that can with a little guidance do many sorts of "research work," but are wholly unable to perform with certainty a qualitative analysis of a comparatively simple substance They may happen to find most or all of its constituents, but they have no confidence in their result, they do not feel sure that they have missed nothing, or indeed that everything they have found is unmistakably present, and generally they have little if any idea of the degree of accuracy of their work. They cannot distinguish between a principal constituent and one that is present in a comparatively small proportion This incompetency must be ascribed very largely to the fact that students are too often urged on to work that a casual observer might regard as more important. The foundation is neglected for the sake of the superstructure

But having regard only to that amount of practice in qualitative work that still remains possible for the average student, there is too often a lack of method that is surprising if not disastrous. As a rule, it is considered desirable to get first an idea of the general character of the substance given for examination by a few dry tests, but these, as often done, are not only of no use, but serve in a conspicuous manner to train the student in the making of careless and imperfect observations, and in the dodging about from one operation to another with no idea of the proper sequence or inter-dependence of the various parts of the work. In the analytical examination of even the simplest of substances, from the

time when the student receives it until he has made his last note, every operation ought to be in an order for which very definite reasons can be given, and the completed work ought to be of such a character that anything added to it would be superfluous, anything taken from it would leave it imperfect, and any change in the order of its various parts would be to its detriment. This character of work is generally sought after in the separation of metals from a solution, but the rest of a qualitative analysis, namely the preliminary examination and the testing for acids, is too often a collection of odd operations, which, if the student is lucky, will lead him sooner or later to the desired result, but if he is unlucky may fail to do so through no fault of his own.

CHAPMAN JONES.

POPULAR LECTURES ON PHYSICAL SUBJECTS

Gemeinverständliche Vorträge aus dem Gebiete der Physik. Von Prof. Dr. Leonhard Sohncke. (Jena: Gustav Fischer.)

IT is a matter of common remark that the books on scientific subjects which reach us from Germany are, as a rule, so special and detailed in character as to be totally devoid of interest, except to those immediately concerned with the subjects of which they treat. This being the case, it is all the more refreshing to meet with such a collection of popular addresses as Prof. Sohncke has gathered together in the volume before us. He has not restricted himself in his choice of subjects to any one branch of physics; on the contrary, the nine lectures of which the book is made up represent as many different divisions of natural philosophy, and were delivered quite independently before various audiences in Germany.

The first lecture of the series bears the somewhat obscure title, "What then?" and was suggested by a great strike among the coal-miners of Westphalia, which led to a temporary cessation of the German coal supply. The author depicts what would be the consequences if the world's coal supply were exhausted, in terms almost as pathetic as those of Prof. Jevons which moved an English Parliament to appoint a commission on the subject. But recognizing that, after all, coal is only stored up solar energy, Prof. Sohncke endeavours to look at the brighter side of the question by discussing the possibility of utilising the sun's energy in other forms, and so enabling man to remain "lord of creation" even in those days when the entire available coal supply of the world reposes on the shelves of some scientific museum.

Equally spontaneous is the lecture on "Migratory Mountains," in which an account of a holiday visit to the north-east corner of Germany gives an opportunity of describing the formation and movements of the mammoth sand-dunes in that locality.

Of the other lectures, that entitled "The revolution in our views concerning the nature of electrical actions" will probably commend itself to most readers because it treats of a subject now exciting general interest. It contains a short history of the arguments and experiments which led to the substitution of the ether theory of electrical action in the place of the older action-at-a-distance theories. While admitting the existence of a medium which transmits both optical and electrical disturbances, the author thinks it more probable that gravitation is a true action-at-a-distance, and in so doing he tacitly denies that a medium is a necessity. The notion of an empty space is so foreign to English men of science of this generation, that we certainly consider Prof. Sohncke's summing-up of the question to be worthy of attention. He says:—"Even if we could finally succeed in proving that action-at-a-distance is really the result of a transmission through some medium, we must not suppose that all difficulties are then removed. For the process of such a transmission is by no means simple, and cannot be explained without further assumptions; on the contrary, very formidable difficulties arise even here. Directly we try to give a concise explanation of the compression of a body and its subsequent expansion when performing elastic vibrations, we find that a choice must be made between two assumptions equally hard to accept. Either matter is itself capable of compression and expansion, or else it consists of separate vibrating atoms to which we must assign the property of exerting mutual forces on each other at a distance."

From a purely scientific standpoint, the lecture on "Newer theories of atmospheric electricity and thunderstorms" is undoubtedly the most valuable of the series, the subject being one on which Prof. Sohncke can speak with some authority. After describing the older theories of the origin of electrical charges in the atmosphere, he discusses those newer ones which were suggested by the discovery of Hertz that ultra-violet light facilitates the discharge of electricity from a charged body. Of these the best known is that of Arrhenius, who supposes the air, ordinarily a dielectric, to be rendered feebly-conducting by the action of light. According to this theory, the earth is negatively charged, and when its atmosphere is illuminated some of the charge is conducted away to the clouds. The conduction must be electrolytic, otherwise the air would become charged. Prof. Sohncke objects to this theory mainly on the ground that the discharging action of light cannot be considered as due to the air in any way, since it is manifested only when the light vibrations fall on, and are absorbed by, the negative electrode. Further, it is not easy to see how elementary gases such as oxygen and nitrogen can be electrolytes. In concluding he defends his own theory, according to which atmospheric electricity is produced when a cloud laden with particles of ice meets another charged with water drops, the electrification being due to the friction of ice against water. In support of his view the author quotes the fact that hailstones are found to be electrified on reaching the ground.

The appearance of a volume like the present one invariably gives rise to some regrets that the whole earth is no longer of one language and one speech, but we hope that some friend of popular science may be induced by the contents of the book to furnish a translation for English readers.

JAMES L. HOWARD.

BRITISH JURASSIC GASTEROPODA

A Catalogue of British Jurassic Gasteropoda, comprising the Genera and Species hitherto described, with references to their Geological Distribution and to the Localities in which they have been found By W H Hudleston, M A, F R.S., F.G S, and Edward Wilson, F G S 8vo, pp xxxiv+147 (London Dulau and Co, 1892)

NEXT in importance to a monograph on any group of fossils is a catalogue of the species giving their distribution, their synonymy, and references to the figures and descriptions The value of such a catalogue is enormously increased when, as in the present case, the authors have made a prolonged and careful study of the subject The late Prof John Morris was able, with scarcely any help from other workers, to publish a critical catalogue of all British fossils; the first edition appeared in 1843, the second in 1854 But since that date so much progress has been made in palæontology that the accomplishment of such a task by any one man would now be an impossibility Prof Morris always hoped to bring out a third edition of his work, and after his death a committee was formed to carry out this project But the labour appears to have been too great and the committee soon ceased to exist This is greatly to be regretted, for although the work must of necessity have been distributed among various authors, a certain amount of uniformity in treatment would at any rate have been secured and publication hastened

In the preface we are told that Mr Hudleston is mainly responsible for the Oolites and Mr Wilson for the Lias Under the term Jurassic the authors include everything from the Lias to the Portland-stone the Rhætic beds, although not regarded as strictly Jurassic, are treated in the supplement The total number of gasteropods recorded by Samuel Woodward from these formations in 1830 was only 89, whereas in the present work the number given is 1015 Of these 15 come from the Rhætic, 314 from the Lias, 681 from the Oolites, and 5 from the Lias and Oolites In the Lias the gasteropods are characterized by the species belonging to comparatively few genera. Although, as far as genera are concerned, the Lias shows considerable affinity to the Oolites, there is nevertheless a great break in the continuity of the species, only five being common to the Lias and Oolites Gasteropods are most abundant in the calcareous beds, so that the Lower Oolites have yielded by far the larger number of forms, the Inferior Oolite being richer than the Great Oolite In the Middle and Upper Oolites there is a decided decline in the gasteropods, especially of the argillaceous beds

After the introductory remarks the authors give a valuable bibliography of the British Jurassic Gasterpoda, and then a list of the genera, in which each is placed in its proper family and reference given to the original description. By the use of different type the genera are divided into four classes, (1) those fully accepted by the authors, (2) those accepted with doubt, (3) those given as Jurassic by other authors but not accepted, (4) synonyms. In the catalogue proper the authors have adopted Morris's plan, each page being divided into two columns, in the larger are given the name of the species, the references, the synonyms, and the cross-references, in the smaller the geological horizon and the more important localities, the locality first named being that from which the type was obtained or the first place from which the species was recorded in Britain The dates of publications are often omitted, but since they can be found in the bibliography this is not very inconvenient except in the case of serials The present *locale* of types is not given, although this would have been a comparatively easy matter, especially since so many catalogues of types have been recently published

With regard to the orthography the authors have kept to the older and more usual method For instance, the capital initial is used for species when derived from proper names, and the single *i* for the genitive is not always adopted Thus we find a considerable variation in the terminations, such as, *Cricki* (p 124) *Crickii* (p 77), *Waltoni* (p 42) *Waltonii* (p 139), *Suessea* (p 29) *Suessii* (p 138), *Wrightii* (p 46) *Wrightianus* (p 70) These are, however, purely matters of opinion and do not in any way detract from the great value of the work, which exhibits so much painstaking accuracy and sound criticism H WOODS

OUR BOOK SHELF

The Year-Book of the Imperial Institute of the United Kingdom, the Colonies, and India, and Statistical Record of the Resources and Trade of the Colonial and Indian Possessions of the British Empire Compiled chiefly from official sources First issue 1892 Issued under the authority of the Executive Council, and published by John Murray, &c Large octavo pp xvi and 824.

THE Imperial Institute has lost no time in issuing a handsome and comprehensive year-book, compiled by the Librarian, Mr J R FitzGerald, who has diligently and successfully gathered together a stack of varied information bearing on the purposes of the Institute It is a question which time alone can answer whether amongst the many admirable year-books of statistics, commerce, and the colonies which have established themselves as annuals of proved utility, there is room for a new and bigger book overlapping their information, and containing few, if any, novel features. It would be out of place to discuss this question in a notice which ought to be confined to the scientific aspects of the work The object of the year book, as expressed in the preface, is to deal "statistically with the physical geography, the natural resources, and the industries and commerce of the Colonies and India," and with certain other related facts It would not be fair to criticise severely the first issue of so large and comprehensive a compilation, but it would help towards the attainment of the compiler's aim if the description of the physical geography of the regions touched upon could be made as full as the historical introductions, and as statistical as the commercial tables More notice ought to be taken of the geology and the character of the soil in the colonies where geological surveys are in progress, and climate certainly deserves better treatment We do not think space would be wasted in giving the mean monthly temperatures and rainfall for the average year, and for two extreme years, at a few representative stations in the larger colonies This information cannot indeed be found in any existing books, but must be worked out from original records which exist abundantly, and are rarely made available to practical workers.

The treatment of natural resources might also be

improved by a firmer grasp of scientific principles The commercial statistics are, as might be expected, much fuller, better arranged, and more serviceable than those relating to physical geography, but we imagine that few members of the Imperial Institute, likely to make use of the book, are without the original records relating to their own department The difficulty of proportion and perspective is rather seriously apparent in the treatment of India, which has to be passed over more lightly than the colonies, because equal detail would involve the sacrifice of much space Thus the great internal trade of India is scarcely touched upon, and the wants and tastes of consumers in the ultimate Indian market, by whom imports are finally absorbed, are not laid before the British merchant

Beneath Helvellyn's Shade By Samuel Barber (London Elliot Stock, 1892)

THIS book consists of notes and sketches in the Valley of Wythburn, and is brightly and attractively written Perhaps the best chapters are those on clouds, the various forms of which have been carefully studied by the author. He has also many interesting remarks on various aspects of Cumberland scenery, on the customs of the people, and on antiquities Occasionally, perhaps, Mr Barber adopts too much the tone of a preacher, but his impressions and ideas are for the most part fresh and vivid The book will especially please those who have themselves felt the charm of Wordsworth's country

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications*]

Dr Joule's Thermometers.

RESPECTING the question asked by Mr Young (NATURE, vol xlvii p 317), I am glad to have an opportunity of stating that shortly after Joule's death I obtained the sanction of his son to examine the scientific apparatus that were left in his house

I found a number of thermometers, and amongst them the two chiefly used by Joule in his researches These thermometers have been placed in my charge for the present. I have made careful comparisons of them with a standard of the "Bureau international des Poids et Mesures," and therefore indirectly with the air or hydrogen thermometer A standard issued by the Technische Reichsanstalt has also been used as a check I spent a good part of last winter on the work and am now only waiting for an opportunity to repeat some of the measurements. The results will be published in due course, and I think will prove of interest As Joule compared his thermometers with one used by Rowland, we shall in this way have an indirect comparison of Rowland's air thermometer with those by which the Berlin and Paris standards have been independently fixed

One question arises on which I should be glad to have some information, and I should be grateful to any of your readers who could help me. The glass of which Joule's thermometer is made does not behave like the English glass now in use; and it would be important to know the probable composition of glass used in England about the year 1840 for thermometric purposes. As my experiments are not concluded I do not wish to speak with too great a certainty; but I believe it will be found that if we could return to the glass of Joule's thermometer, we should have a substance as well and possibly even better adapted to the manufacture of thermometers than the modern Jena or French thermometer glass.

I am sorry I cannot give a very definite answer to Mr Young's question Joule does not, as far as I know, anywhere give the actual readings of the freezing point, but only its changes. Rowland, in quoting the comparison between Joule's thermometer and his own, gives 22 62 as the actual reading of Joule's zero I have not at the present moment access to Rowland's paper, and have no note of the date at which this comparison was made (either 1879 or 1880)

Such a formula as that given by Mr Young can, however, only have a limited application The zero of a thermometer depends on the temperature at which the thermometer has been kept previous to its immersion into ice, and with properly annealed thermometers the secular changes are much smaller than the temporary ones. Last winter Joule's thermometer showed changes in zero from 23 51 to 23 00 on the arbitrary scale, the original temperatures varying from 7° to 30°.

All observations lead to the conclusion that the secular changes of a thermometer gradually vanish, so that the zero corresponding to any temperature approaches a limit Mr. Young's formula would make the zero rise indefinitely

ARTHUR SCHUSTER.

Dust Photographs and Breath Figures

YOUR two correspondents on February 9 add interesting instances of these phenomena. I am sorry that one of my statements was not clear In saying "Two cases have been reported to me where blinds with embossed letters have left a latent image on the window *near* which they lay," I meant to describe them as not in contact

I have questioned my neighbour Dr. Earle again as to his case The plate-glass window of an hotel in London has on the inside a screen of ground glass lying near but not touching upon the latter are the words "Coffee Room" in clear unfrosted letters. One day as he was at breakfast the screen was taken away, but the words were left plainly visible on the window, and no washing would remove them. The other case is curiously similar, but each narrator was ignorant of the other's tale A friend, Mr Potter, asked me if I knew whether a house in which he was lodging had been an hotel, for on misty days they saw "Coffee Room" on one of the windows I remembered the house had been an hotel two or three years previously, and there had been brown gauze blinds with gilt letters.

Mr Thiselton-Dyer's observation appears not so much akin to these two as to the dust picture of a water-colour drawing of which I spoke in my former paper

I look forward to seeing the effects at Canterbury

Winchester College, February 13 W B CROFT

Fossil Plants as Tests of Climate

MR DE RANCE'S note relating to the above subject in NATURE, p 294, mentions that "Heer has determined a magnificent flora of more than 350 species from these northern tertiaries, and that he at once pointed out the absence of tropical and subtropical forms" My contention, founded on an attentive study of his determinations and of the original specimens in London and Dublin, and to some extent in Copenhagen, is that not fifty, or perhaps not the half of fifty, of these determinations are entitled to the smallest weight, and again that though at first he saw nothing subtropical in the flora, he subsequently declared the presence of palms, &c., upon utterly insufficient data. While, however, wishing to rid the "magnificent" flora of 300 or more useless and misleading encumbrances, I am far from wishing to depreciate the extraordinary significance and value of that which remains, and which clearly shows that in early Eocene times the coast of Greenland supported in certain places forests which included the redwood, the plane, and even the magnolia, associated with many more northern forms. This is consistent with the tropical vegetation existing during a part of the possibly contemporary lower tertiary period in the south of England. Both facts are sufficiently inexplicable, but there is no occasion to magnify the difficulties they present As to the Greenland floras they have not been proved to contain any forest trees that might not, and which in fact do not, flourish in their modern representatives, when planted in certain favourable spots on the west coast of Ireland, and even of Scotland. We are not even obliged to assume that Greenland as a country was characterised by such vegetation, for this might be as erroneous as to regard Ireland or Scotland as countries generally characterised by forests of arbutus. The flora of a country is in fact most likely to be preserved in its most sheltered spots, in lake bottoms like parts of Killarney, or where small rivers quietly steal into the tidal waters of deeply recessed bays like those of Bantry and Kenmare, in forest pools like some in the Mount Stewarts' woods of Bute, and

in the backwaters and marginal pools of the lower reaches of larger rivers, we are not only entitled, but we are bound to consider this to have been the case in Greenland, and to base our estimate of its climate in the lower tertiaries upon this view and no other. Now what geologists and physicists ought to do, and what they resolutely won't do, is before going farther afield for cause and effect, to take the map of the world on Mercator's projection, and consider how far, if the Atlantic were a closed ocean to the north, as we know it must have been, the required climatic conditions would be produced The difference between the arbutus nooks of Ireland on the one side and the desolation of Labrador on the other is brought about solely by ocean currents At the period of the Greenland floras the arctic currents were excluded, and consequently the whole Atlantic basin was filled with the circulation of equatorial and temperate waters only The distribution of plants and animals renders it extremely probable that during much of the tertiary period, the antarctic waters were equally excluded from the Atlantic by land connecting Africa and South America. What, under these circumstances, would happen to the climate of the Atlantic littoral? It would, it appears to me, be more philosophical to dispose of this question, which is supported by a weight of evidence, before invoking shifting of the earth's axis, or other hypothetical causes supported by none. J STARKIE GARDNER

London, February 13

An Optical Phenomenon

IN NATURE, vol xlvii p 303, you mention that "a beautiful optical phenomenon, which has not yet been satisfactorily explained, is described by M F Folie in the *Bulletin* of the Belgian Academy" From what follows, it is evidently the same as that described in Tyndall's "Glaciers of the Alps" (Murray, 1860), p. 177 *et seq* Tyndall gives a description of it in a letter from Prof Necker to Sir David Brewster, from which I quote the following —"You must conceive the observer placed at the foot of a hill between him and the place where the sun is rising, and thus entirely in the shade, the upper margin of the mountain is covered with woods, or detached trees and shrubs, which are projected as dark objects on a very bright and clear sky, except at the very place where the sun is just going to rise, for there all the trees and shrubs bordering the margin are of a pure and brilliant white, appearing extremely bright and luminous, although projected on a most brilliant and luminous sky You would fancy you saw these trees made of the purest silver"

Prof Necker says that he saw it at the Saleve, which is not so high above the Lake of Geneva as some of our British mountains above the sea, and has no permanent snow near it, so that M. Folie's suggestion, that it is due to light reflected from snow, must be wrong I have seen it from the Konig-See, near which I believe there is no permanent snow

This appearance is always to be seen under the circumstances described, when the sky is clear and bright enough. I had read of it in Tyndall's book, and when in the Alps I sought for and found it I have often seen a distant approach to it produced by furze bushes, quite near, seen against sunlight, and by leaves against moonlight JOSEPH JOHN MURPHY

P S —Ruskin somewhere describes this phenomenon.

Belfast, February 6

Foraminifer or Sponge?

A PAPER by A Goes "On a peculiar type of Arenaceous Foraminifer from the American tropical Pacific, *Neusina Agassizi*," has just been published in the "Bulletin of the Museum of Comp Zoology, at Harvard College," vol xxiii No 5, in which the author describes some remarkable forms dredged by the *Albatross* expedition in the Pacific of Central America. They are supposed to be foraminifera, are of leaf like shape, measure up to 190 mm in breadth, and are marked by concentric lines of growth Their interior shows a stroma, consisting of fine chitinous threads, enclosing sand and *débris* of shells. Without wishing to recapitulate all the various points of structure, I will only say that there can be no doubt that these forms belong to Hæckel's deep sea keratosa (see *Challenger* report, vol. xxxii.) from the tropical Pacific, and I should think that *Neusina Agassizi* is identical with *Stannophyllum zonarium*, Hæckel I happen to have here a *Challenger* specimen of this latter species, kindly lent to me by the Manchester Museum, and its microscopic examination convinces me of the identity of the two forms.

University College, Liverpool R. HANITSCH.

Unusual Origin of Arteries in the Rabbit

TOWARDS the close of last month Prof W N. Parker reported in your columns an abnormality in the veins of the rabbit, and although the same interest does not attach to it, it may be worth while recording an unusual arrangement of the vessels arising from the aortic arch In the case which has just come under my notice, the two carotids arise together from the arch, at the point usually occupied by the innominate artery, while the right subclavian artery arises beside the left subclavian, which occupies the usual position PHILIP J WHITE.

Holmes's Comet

ON February 11, 10h to 10h 35m, I re-observed this object with powers of 40 and 60 on my newly-silvered 10-inch reflector The comet was in the same field as β Trianguli and south preceding that star I found it fairly conspicuous The nucleus, or brighter portion of the head, presented a distinctly granulated appearance Applying a power of 145, single lens, I saw that it really consisted of a number of very small knots of nebulosity, so closely approximating the stellar form that they might readily have been mistaken for one of the very faint, barely resolvable clusters in which the components are only to be caught by glimpses The multiple nucleus was involved and surrounded with feeble nebulosity, and a faint tapering tail flowed from it in a N E direction I believe that outlying this there was an excessively faint fan-shaped tail, but could not be absolutely certain

The sky was not good, being lighter than usual, with suffused mist On February 12, at 10h 15m, I picked up the comet again, but details were invisible, owing to the veil of thin cloud overspreading the N W sky at the time

Bristol, February 13 W F DENNING

HELMHOLTZ ON HERING'S THEORY OF COLOUR

THE following translation of the critical account given by von Helmholtz of the colour-theory of E Hering, in the new edition of his *Handbuch der Physiologischen Optik*, commencing at page 376, has been made by Prof. Everett for NATURE The translator aims at clearness rather than literal rendering, and three obvious misprints in the paragraph on the transformation of coordinates have been corrected "Lambert's colour-pyramid" is another name for the "cone of colour" described in Maxwell's papers and in § 1074 of Everett's "Deschanel"

This much-talked-of theory is a modification of Young's theory, which, by the choice of other fundamental sensations, endeavours to give better explanations of what it regards as immediate facts of internal observation It assumes three elementary sensations, related to three different parts of the nerve-apparatus or "visual substance" Two at least of these physiological processes exhibit the opposition of positive and negative One of the three "visual substances" gives in the condition of excitement the sensation of white, and in the condition of rest the sensation of black. The second gives the two sensations of blue and yellow, which are accordingly designated "opposed colour-sensations" The third gives the other pair of "opposed colour-sensations," red and green But by "red" is denoted not the colour usually so called, but the complementary of green, which is purple.

It is possible to specify "elementary sensations" (in the sense in which we have previously defined the term) which would correspond to Hering's elementary sensations, and would be capable of giving by their combination all other colour-sensations. If we take three rectangular axes of coordinates, x, y, z, as the edges of Lambert's colour-pyramid, x corresponding to red, y to green, and

z to violet, Hering's coordinates u, v, w will have the values

$$u = \frac{x+y+z}{\sqrt{3}},\quad v = \frac{x-z}{\sqrt{2}},\quad w = \frac{x-2y+z}{\sqrt{6}}$$

u denoting the white element, and being measured along the axis of the pyramid; w denoting the red-green element, and being measured at right angles to the axis of white, in the plane containing the green edge of the pyramid; v denoting the yellow-blue element, and being measured at right angles to the plane of u, w.

Positive values of w correspond to purple red, and negative values to green. Positive values of v correspond to yellow, and negative values to blue.

I give these equations in this definite shape for the purpose of showing, by a definite system of representation, that the arbitrariness which attends the choice of three colours, in terms of which the rest are to be specified, affords sufficient latitude to admit of the employment of three such different specifying elements as are adopted by Hering.

If only positive values of x, y, z are to be admissible, the expression for u shows that every kind of light must excite the white sensation positively, and consequently that no kind of objective light can produce a pure sensation either of the red-green or of the yellow-blue kind. Hence the pure unmixed "opposed colour-sensations" are such as we never have had or can have, and are separated from all colour-sensations that we have ever had by a much wider gap than the pure sensations which Young's theory supposes, although these latter extend somewhat beyond the range of objective colours. By subjecting portions of the retina to special influences (as we shall explain in treating of after-images) we can at least approximate to Young's elementary sensations, while these same methods, when we attempt to approximate to Hering's pure sensations, give results opposite to what his theory would lead us to expect.

Hering assumes, in accordance with the brief expression of his theory in the above equations, that white light excites only the white-black visual substance and excites it always positively, that yellow light, besides doing this, excites the blue-yellow visual substance, as does also blue light, but in opposite sense. On the other hand, when blue and yellow lights are in exact equilibrium, they have no action on the blue-yellow visual substance.[1] Similar remarks apply to the excitements of the red-green visual substance by red and green light.

The sensation of luminosity is identified by Hering with the sensation of white. He accordingly maintains that the pure sensation of blue or of yellow involves no sensation of luminosity. I must confess that personally I can form no conception of a colour which has no degree of less or greater luminosity, and therefore think such an abstraction not tolerable in a system which, on other points, makes its appeal to the immediate testimony of inner consciousness, and claims by this means to establish its superiority to other systems.

Differences of intensity must, however, occur in the opposed colour-sensations if they involve no difference of brightness. In comparing saturated blue with equally luminous pale blue, Hering would regard the white sensation as equally intense in both, but the blue sensation as stronger in the saturated blue.

As the physiological basis of the "opposed colour-sensations" Hering takes the two opposite processes of organic change, namely, the decomposition of the organic mass by activity, and its restoration under the influence of the circulation of the blood, which carries oxygen stored up in it and feebly united with it. The former process is called *dissimilation*, and the latter *assimilation*. Which of the two opposed sensations corresponds to dissimilation and which to assimilation is left undecided, both in the case of blue-yellow and of red-green. The physiological improbabilities of this assumption have in part been pointed out already, and we shall return to the subject in treating of after-images.

This assumption of double nerve-working was originally applied by Hering to the white-black visual substance also. At the present time he adheres to the hitherto-received doctrines of nerve-physiology to the extent of holding that, in the case of this substance, all light excites only dissimilation and the sensation of white, and on the other hand want of light produces only assimilation and restoration of excitability. That during this latter process a sensation of darkness is experienced, all are agreed. The difference is purely theoretical. According to the older view, which I have defended, we must, in order to perceive that there is luminosity in a particular part of the field of view at a given time, be able to distinguish at another time that this perception is wanting. This perception that a sensation which might be there is not there contains in itself a testimony as to the condition of the organ at the time, which is different from all sensations of incident light, and in this sense we call it also a sensation—the sensation of darkness.

Hering, on the contrary, maintains that the sensation of black must have its own special physiological basis of excitation, and seeks it in assimilation, going on in the white-black visual substance.

From the foregoing account the reader will gather that Hering's theory, if we overlook its physiological views, is able to explain all hitherto established facts of colour mixture as well as, but not better than, Young's theory. It differs only in its special choice of elementary excitations, and this choice, if we admit negative values of them, suffices for expressing the facts, just as any axes of co-ordinates suffice for a problem of solid geometry.

Hering's objections to Young's theory reduce themselves, in his latest statement, to the following:—

"In the Young-Helmholtz theory, the assumption of the three elementary colour-sensations is *à priori* repulsive, because these sensations are not presentable, and notoriously, according to necessity, now one set and now another set of elementary colour-sensations are assumed."

As to this, I have already remarked that the fundamental sensations of Young's theory, in so far as they differ from objective colours, can be approximated to, by the method of partial fatigue of the retina, much more closely than Hering's pure opposed-colour-sensations. If different upholders of Young's theory have made different assumptions as to the three primary colours, and have assigned different weights to various facts which bear on the distinction, this affords no justification whatever for the imputation that they have changed their assumptions according to necessity. It is always better to acknowledge existing doubt than to dogmatise.

Hering goes on, "If the excitations belonging to the three elements have correspondingly distinct physiological causes, one would expect that these sensations would have something special about them."

This they have, in my opinion, in the prominent glow of colour-saturation, for which, again, the theory of opposed-colours furnishes no basis of explanation.

He continues, "Yellow gives, for example, much more the impression of a simple or elementary sensation than violet, and yet we are told that the latter is an elementary sensation and the former a mixture of simultaneous sensations of red and green, or at least, in some way, the product of the simultaneous existence of the principal excitations corresponding to these two elementary sensations."

What a deceitful test apparent inner consciousness is in such matters, we can see from the examples of two

[1] This was a point which Hering left doubtful in the earlier statements of his system, so that it was not clear whether he assumed three or six independent variables. According to his more recent explanations the statement given in the text may fairly be said to represent his view.

such authorities as Goethe and Brewster, both of whom believed that they saw in green the blue and yellow, of which, being misled by experience with pigments, they believed it to be composed.

He goes on, "Helmholtz says, quite correctly, 'so far as I see, no way has been found of determining one of the elementary colours except the investigation of colour blindness' This investigation has notoriously not confirmed Young's theory"

This would, even if it were true, be in itself no argument against the admissibility of the theory The theory of colour-blindness seems, as we shall shortly see, to be a particularly hard crux for Hering's theory, while the hitherto well-established facts of red-blindness and green-blindness admit of comparatively easy and perfect explanation by Young's theory

He adds, "And the three sets of fibres, which, however, as Helmholtz remarks, are not essential to the theory, have hitherto been sought for in vain"

This objection applies to Hering's theory as much as to Young's

The reader will easily convince himself that these objections are of no weight whatever He follows them up by an enumeration of contradictions and inaccuracies which he professes to have found in Grassmann's and my own explanation of Newton's law of colour-mixture, and partly also in that of Kries, errors which, even if they existed, would in no way tell against Young's theory, but only against its interpreters Here, however, the obscurity seems to me to lie on the side of our opponent

These objections arise out of the fact that, in mixtures of a saturated colour with white, the tint of the mixture sometimes seems changed (pale red for example approaches more to rose, and pale blue to violet), and that, on the other hand, with increase of intensity, the colours of the spectrum appear sometimes paler, sometimes yellower But if we speak of those elementary excitations which, from the point of view of Newton's law, are alone entitled with certainty to the name of elements, as being able to coexist without mutual disturbance, then the only sensation which can with certainty be regarded as corresponding to the coexistence of a white and a red elementary sensation is that which comes into existence under the simultaneous influence of the corresponding white and red lights The term "elementary sensation" is in this connection to be taken, of course, not in the narrow sense of Young's hypothesis, but in the wider sense above explained—the sense in which we speak of linear relations between colour-sensations and linear superposition of elementary-sensations. In the domain of colour-mixture we know nothing of any elements but these superposable ones, and if we would preserve a constant meaning for our colour-equations we must interpret them in this sense, as I have explained above. This is what H Grassmann and myself have always done

Moreover, erroneous estimates of the difference between a pale and a more saturated colour are liable to be made, and hence those colours which are really most diluted with white do not always appear the palest If, without sufficient experience of colour-mixture, we only guide our judgments by similarity of sensations, we are liable to make mistakes as to which colour contains white The question of the power of perceiving differences will therefore arise. Further, it is found that colours of very strong luminosity do not differ so much from one another in the sensations they produce as colours of moderate luminosity,—a fact which finds its explanation in Young's theory, of which it is a natural consequence Colours when highly luminous appear more similar to one another and more similar to white We express this by calling them pale as compared with colours of feebler luminosity I have, however, already mentioned that the law of superposability ceases to be applicable when the luminosity is excessive

Nevertheless, in view of the fact that simple colours of high luminosity are always as saturated as colours of such luminosity can be, it is not necessary, or rather it is not correct, to designate them as less saturated The true statement is that differences of tint become more uncertain at high intensity- an uncertainty which attaches also to the estimation of the intensity itself, as has long been known

If Hering's sensation of white and opposed-colour-sensations are truly to deserve the name of elements or constituent parts of sensation (as he plainly intends, since he assigns to them special visual-substances) either he must acknowledge them as the elements deducible from the law of addition, or else they are purely hypothetical processes of whose existence and superposability no one knows anything His polemic against Grassmann and me then amounts to this—that at a time when his hypothesis had not been propounded we did not speak in the sense of it

Hering seems to regard as the chief point of superiority of his own hypothesis its closer conformity with the names which have established themselves in language—names which, as I have explained above, relate rather to the colours of material bodies than to the colours of light To this circumstance it is, in fact, indebted for a certain amount of popularity and facility of apprehension He himself assumes that these names have sprung from an immediate perception of the simple elements of sensation by a kind of inner consciousness, and thinks that he has thus very certain and immediate knowledge of the pure red-sensation, the pure white-sensation, and so on

In his publication of 1887 he has discussed the possibility of assuming, instead of three or six simple processes of sensation, a larger and perhaps indefinitely great number, and a corresponding number of "elementary powers" for the several kinds of objective light He, however, gives the geometrical representations of such actions in such a manner that practically these powers all depend on three independent variables On the other hand, as regards these independent variables, which are the most important factors in the problem, he gives as good as no clue to them, he only seeks to remove them as far as possible from the sphere of physiology For my own part I am able to understand this whole series of descriptions only as meaning that an arbitrary number of visual substances can be assumed to exist in the brain, and that their respective strengths of excitation are different functions of the same three independent variables, each visual substance being unaffected by the excitations of the rest, and the excitation of each being susceptible of direct apprehension in consciousness I do not think it is necessary, in this book, to go further into such hypothetical views

Hering especially claims the credit of opening up the way to understanding colour-blindness. He makes all dichromasy depend upon a single cause, namely want of sensibility in the red-green visual substance The difference between red-blindness and green-blindness is, according to him, attributable to different colourations of the media of the eye, partly of the yellow spot of the retina, partly of the crystalline lens

These colourations are chiefly met with in the sick or the very old, and, when occurring in otherwise useful eyes, are not of such strength that they could bring out conspicuous deficiency of brightness in different parts of the spectrum

The colouration of the yellow spot of the retina takes effect in a very limited but very important part of the field of view, and in only a narrow band of the spectrum The most trustworthy observations on the influence of the wave-length of the incident light upon the strength of the red and green excitations, have been made with

kinds of light not liable to be absorbed in notable degree by the yellow pigment On the whole, it is accordingly found that this pigmentation is subjectively influential only in cases in which the rays in the neighbourhood of the line F play a prominent part, as, for example, in a certain mixture of this blue with red (mentioned on page 354) which, if it looks white when our eyes are directly fixed upon it, will show blue predominant when we look in a slightly different direction

As far as hitherto-known facts go, it appears very improbable that Hering's theory of dichromasy can be carried through Nevertheless, further observations in this direction are very desirable. The influence which the colouration of the yellow spot has in individual eyes can be estimated by comparing the appearances of colour-mixtures in the centre of the field of view with their appearances very near the centre Such comparisons will show with certainty where such influence is present and where it is absent

The following is a summary, by Prof Everett, of two passages from the new edition of Helmholtz's "Physiological Optics," which are important as supplementing the foregoing critique of Hering's theory —

In discussing the results of experiments for determining the exact positions of the three elementary sensations with respect to actual colours, in Newton's diagram or in Lambert's pyramid, Helmholtz represents the results by a triangle with the three elementary sensations at its corners, and with the colours of the spectrum plotted along a curve which lies entirely in the central portion of the triangle He says, p 457 —

"This curve shows that every simple colour excites simultaneously in the trichromic eye the three nerve-elements which are sensitive to light, and excites them with only moderate differences of intensity If we then hypothetically refer all these excitations to the presence of three photo-chemically alterable substances in the retina, we must conclude that all three of these must have nearly the same limits of sensibility to light, and must show, in the rates of their photo-chemical actions for the different wave-lengths, only secondary variations of moderate amount Similar variations, arising from the presence of foreign substances, from substitutions of analogous atom-groups, and so on, occur also in other photo-chemically alterable substances as used in photography, for example, in the different haloid salts of silver"

In a mathematical discussion of colour-blindness, commencing at p 458, he points out that in dichromic vision there must be a linear relation between the three independent elements of trichromic vision, and in Lambert's colour pyramid there must be a certain line through the vertex, such that any plane drawn through it is a plane of uniform colour Newton's diagram of colour may be regarded as contained in any plane which cuts the axis of the pyramid, and it is very important to determine the point in which the above-mentioned line cuts such a plane, for any line in Newton's diagram that passes through this point is a line of uniform colour to the dichromic vision in question Experiment shows that it always lies outside the triangle of actual presentable colours

Addendum

Prof. Everett adds the following remarks of his own on the present position of the problem of colour vision.—

On the one hand, it is established, as a fact of experiment, that the excitation of colour-sensation in the normal eye depends upon only three variables, and that their effects are superposable, so as to admit of being expressed by equations of the first degree, otherwise called linear equations. The simplest choice of three variables is that adopted in Young's theory, because it only requires positive val[illegible] of the variables.

On the other hand, the various colours regarded as subjective appearances do not naturally class themselves under a threefold heading Yellow does not look as if it consisted of red and green Colour-sensations as known to us in consciousness are not threefold but manifold

The two facts taken together seem to imply two successive operations intervening between the incidence of light and the perception of colour The first operation is threefold, and may consist (as above suggested by Helmholtz) of the photo-chemical decomposition of three different substances The second operation consists in the effects of the first operation upon a complex organism, and the distinctions of colours as we see them arise out of the nature of this organism

The number of independent variables required for specifying the condition of a system is a very different thing from the number of well-distinguished states in which the system can exist For example, the state of a given mass of water-substance is completely determined if its volume and temperature are given, and therefore depends on only two variables But the number of its well-distinguished states is three In like manner colour depends on three variables, but the number of well distinguished colours, besides white, may be said to be seven, namely the six principal colours of the spectrum and purple

What differences of condition in the organism correspond to these eight distinct appearances in the field of view, and how these different conditions are produced by the three primary excitations, are problems awaiting solution.

AUTOMATIC MERCURIAL AIR-PUMPS

OF late years, and more especially during the last decade, men of science have devoted much thought and ceaseless energy to the invention of an apparatus which should admit of the automatic working of mercurial air-pumps Of the numerous inventions brought forward, the ingenious apparatus of Schuller and Stearn are especially deserving of mention

But notwithstanding the present extensive employment of the mercurial air-pump in science as well as in technics these appliances are neither much known, nor have they been used to any great extent, although they are of great importance, and would probably be very advantageous This may be explained by the fact that they are wanting in the necessary simplicity and trustworthiness, without which the advantages of automatically working mercurial air-pumps are somewhat doubtful

We shall describe now an apparatus for the perfectly trustworthy and automatic working of mercurial air-pumps, as well as the shape of the glass pump used in connection with it, which, while possessing the greatest possible simplicity, admits of the highest rarefactions hitherto known

The figure shows the automatic apparatus in connection with an improved Toepler mercurial air-pump. The glass ball H is connected on the one hand by flexible tubes with the pump Q, on the other hand by the tube L with the accumulator M. The water-pipe K runs into the bottom of the accumulator, and by means of a specially-constructed three-way cock K can either be connected with the hydrostatic pressure-pipe K_1 or the discharge-pipe K_2

If water under pressure is admitted through the tubes k_1, K and k into M, the air contained in M is compressed This air again exerts a pressure through the tube L on the mercury contained in H, and drives it into the pump Q. As soon as the mercury has risen sufficiently high and the cock K is reversed, the compressed air forces the water out again through k, K, and k_2, and the mercury

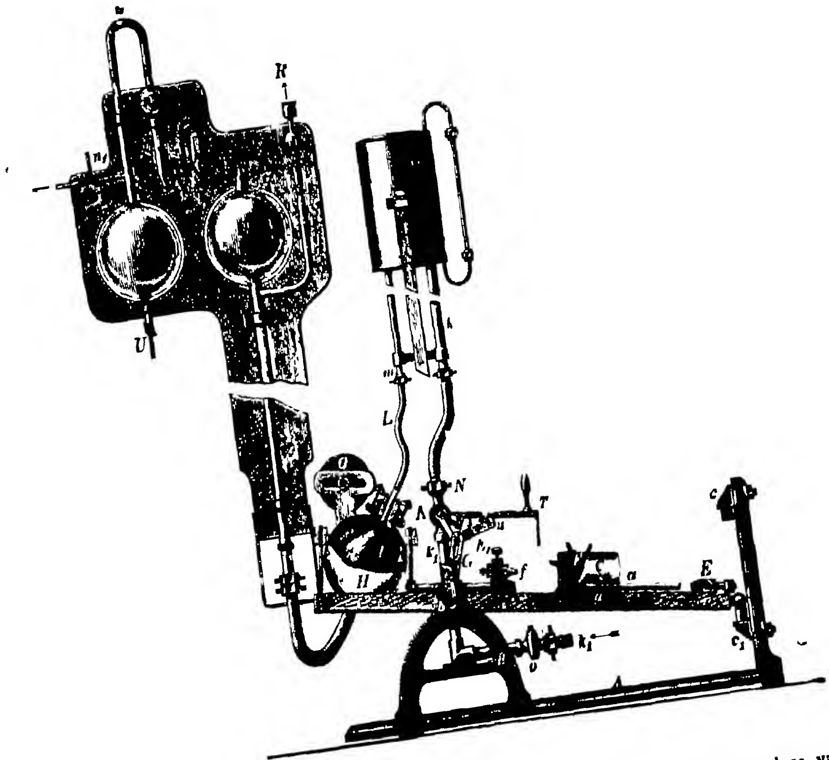
falls down on account of its own weight] out of the pump Q back into the ball H.

The reversing of the three-way cock, and therewith the automatic action of the pump, is effected in the following manner.—The ball H rests on a frame D, revolving about the axis b, and the motion of which is limited by the ledges c and c_1. A lever G is attached to the frame not far from the axis, and by means of a peg, when the balance D reverses its position, also turns the cock. When the ball H is entirely filled with mercury the balance D rests on the upper ledge c. If the pump is set in motion the left side of the balance D becomes lighter in proportion to the amount of mercury forced out of the ball H into the pump, until at last the weight C on the right-hand side becomes heavier, and the balance thereby attains the position shown by the figure. The three-way cock is also reversed by this motion

the adjusting of the height of the mercury can be easily and accurately done up to a centimetre.

It goes without saying that every mercurial air-pump not provided with cocks can be worked by the apparatus just described. But the improved construction of the Toepler pump, drawn likewise in projection in the figure, has proved to be especially practical. The following is a description of its automatic working:—

If the cock t_1 is connected with an hydrostatic air-pump, the ball Q of the pump and the space R, which is to be evacuated through the tube S, is pumped out up to the tension of the vapour. The mercury then rises in the tube R almost to the height of the barometer above its level in the ball H. If the automatic apparatus is then set in motion, the mercury enters the ball Q and the tube S, thus cutting off the connection with R, while any further rising of the mercury



Thus, as already described, the water current is now cut off, the water present in M flows out through K_2, and the mercury goes back from the pump Q into the ball H.

During the tipping over of the balance, however, the sliding weight C has run down its inclined plane to a ledge, E, so that it now exerts a pressure on the lever arm. Its momentum is so calculated that the mercury in the pump must have fallen to the point p, and flowed back into the ball H before it again overweighted, and moves back the balance. The weight C then slides back again to the left until it rests against its left ledge, and the play of the pump recommences. It will easily be seen that the height to which the mercury rises in the pump, the mass of the sliding weight being a constant quantity, depends only on its final positions, and that, therefore,

in the tube S is prevented by a glass valve v, it passes through the first V-tube r_1 filling the little vessel r_2 and rises through s_1 into the ball n, driving before it the air which was before shut off in Q. At this moment so much mercury has been forced out of the ball H into the pump Q, that the balance is turned, the mercury flows back out of Q into H, forming vacua in r and Q, as the little mercury-threads remaining in the side-tubes r_1 and s_1 form shut-off valves. As soon as the mercury has fallen below the entrance-point of S into E the pressure in R and Q become equal, the denser air flowing out through S into Q. The time during which Q is connected with R may be determined at will by changing the right ledge of the sliding weight. Then the balance again changes its position, the mercury rises in

V, and so on When the pump has made a few strokes in this manner, a lever T is let down, so as to rest on the ledge *u* The wheel F provided with six pegs is now turned a tooth farther each time the weight C slides from the left to the right, and the ledge-peg *f*, which when the lever was raised caught each time into a notch of the peg-wheel, rests for the length of five strokes of the pump against the circumference of the wheel, and does not catch into the notch until the sixth stroke As the rising of the quicksilver in the pump is in the inverse proportion of the momentum of the counter-weight in its left final position, if the ledges and peg *f* are rightly placed, it will when ascending be driven five times into the little hollow space r_2 and only at the sixth into the ball *n* In consequence of this the little air bubbles are accumulated in the highly evacuated space r_1 in which they ascend owing to the slight counter-pressure, and forming larger bubbles, and having easily overcome the somewhat greater counter pressure of the mercury column r, they rise into the ball P

All these manipulations are performed *entirely automatically* by the apparatus At the same time that the toothed wheel has commenced working (*i e* when the volume of air pumped out by the pump has sufficiently diminished) the vessel P is entirely cut off from the hydrostatic air-pump by the cock t_1, thus ceasing to act The mercury of the pump is entirely shut off on *both sides* from the exterior air, and only in contact with perfectly *dry* air After stopping the pump, concentrated sulphuric acid may be sucked up into P, which dries up entirely The mercury is shut off from M by a caoutchouc bag, I

The following experiments were made at the Physical Institute of the University of Berlin

400 c cm (cubic centimetres) were evacuated to 1 1000 m m in ten minutes, 4000 c cm. = 4 litres, in an hour

The highest rarefaction hitherto obtained has been about from 1/6000,00 – 1/800,000 m m = to about $\frac{1}{4560000000}$ – $\frac{1}{608000000}$ atmospheres

The pump is supplied by Messrs E Leybolds Nachfolger, Cologne (Germany) AUGUST RAPS

CRYSTALLISED CARBON

IN the course of some researches on the properties and modes of formation of the various forms of carbon, M Henri Moissan has succeeded in reproducing the variety of diamond known as *carbonado*, or black diamond, and has even obtained some minute crystals of the colourless gem. An account of his results in the *Comptes Rendus* of February 6 is followed by an article on the reproduction of the diamond, by M Friedel, and some congratulatory remarks by M Berthelot

As long ago as 1880 Mr Hannay[1] indicated the formation of diamond-like crystals on heating under high pressure, in a tube of iron, a mixture of lithium, lamp-black, essence of paraffin, and bone oil It was then supposed that the nitrogenous compounds of the last substance played the most important part. In M Moissan's new process carbon obtained from sugar is dissolved in a mass of iron, and allowed to crystallise out under high pressure. To produce this pressure the expansion of iron during condensation is utilised The carbon is strongly compressed in an iron cylinder closed with a screw-stopper of the same metal A quantity of soft iron, weighing about 150 or 200 gr, is melted in the electric furnace in a few minutes, and the cylinder is plunged into the molten mass The crucible is at once taken out of the furnace and splashed over with water. When the external crust is at a red heat the whole is allowed to cool slowly in air.

The metallic mass thus obtained is attacked by boiling hydrochloric acid until all the iron is removed There remain three forms of carbon graphite in small quantity, a chestnut-coloured carbon in very small needles, such as has been found in the Cañon Diablo meteorite, and a small quantity of denser carbon which has to be further isolated For this purpose the mixture is treated alternately with boiling sulphuric and hydrofluoric acids, and the residue decanted in sulphuric acid of density 1 8 It then contains only very little graphite, and various forms of carbon After six or eight treatments with potassium chlorate and fuming nitric acid, the residue is boiled in hydrofluoric acid and decanted in boiling sulphuric acid to destroy the fluorides It is then washed and dried, and bromoform is employed to separate out some very small fragments denser than that liquid, which scratch the ruby, and, when heated in oxygen at 1000°, disappear

Some of these fragments are black, others transparent The former have a rough surface, and a greyish black tint identical with that of certain carbonadoes, they scratch the ruby, and their density ranges from 3 to 3 5 Some pieces have a smooth surface, a darker colour, and curved edges The transparent fragments, which appear broken up into small pieces, have a fatty lustre, are highly refractive, and exhibit a certain number of parallel striæ and triangular impressions

During combustion in a current of oxygen at 1050°, some of the fragments left cinders of an ochreous colour, usually preserving the original form of the small crystal—just as in the combustion of impure diamonds

As indicated already by Mr Sidney Marsden,[1] silver heated to 1500° in presence of sugar carbon is found to contain on cooling some black crystals with curved edges M Moissan has found that high pressure is indispensable He heated silver till it boiled briskly in contact with carbon, and found that a certain quantity of the latter was dissolved By suddenly cooling in water, a portion of liquid silver, cooling inside a solid crust, was subjected to a very high pressure No diamonds were formed, but rather a large crop of carbonadoes of densities ranging from 2 5 to 3 5, thus forming a series connecting graphite with diamond Bromoform separated a carbonado, which scratched the ruby and burned in oxygen at 1000° A quantitative determination of this reaction showed that 0 006 parts of this substance gave 0 023 of carbonic acid

M C Friedel describes an experiment in which he obtained a black powder capable of scratching corundum by the action of sulphur on molten iron containing 4 per cent of carbon But the question of the production of diamond powder by this means is as yet an open one

M Moissan is continuing his researches on the solubility of carbon in iron, silver, and their alloys It is to be hoped that he will soon be able to exhibit artificial true diamonds of a more imposing size

LINES OF STRUCTURE IN THE WINNEBAGO CO METEORITES AND IN OTHER METEORITES[2]

THE ground and polished surface of a Winnebago Co. meteorite showed to me some interesting markings Subsequent examination revealed like markings in other meteorites Perhaps these markings have been described. If so I have no recollection of the description, and therefore it seems worth while to call attention to them

The polished surface of a small Winnebago stone, three or four square centimetres in area shows several hundreds of bright metallic points. The larger iron particles in this surface have great varieties of shapes—the smaller

[2] Reprinted from the February number of the *American Journal of Science*

ones are usually mere points When seen with a lens, or even at a distance from the eye suited to distinct vision there does not appear to be any regular structure or arrangement of the bright points But if the surface is so held as to be a little beyond the place of distinct vision, and at the same time, turned around in such a way as to reflect always a strong light to the eye, either skylight or lamplight, there appear lines of points across the polished surface of the stone, which suggest very strongly the Widmanstaetten figures on metallic meteorites At times, as the stone is turned, no lines can be detected Again one set of parallel lines or two sets crossing each other become visible Some of the sets are very sharply manifested, and some are so faint as to leave one in doubt whether the lines are real or only fancied There are on the surface in question six or eight of these sets of lines

A second surface was ground nearly parallel to the first, at about one centimetre distant from it, and like lines appeared on this parallel surface Some of the lines, but not all of them, corresponded in direction in the two surfaces Four more surfaces approximately at right angles to the first surface, and corresponding to the faces of a right prism, were then ground, and upon these surfaces the like sets of lines appear with more or less distinctness

A slab of a Pultusk stone 6 × 7 centimetres shows over its entire surface like markings Something like a curvature of the lines appears in one instance, but in general the lines run straight from side to side of the slab The slab is six millimeters in thickness, and most of the sets of lines have the same directions upon the two sides

A Hessle stone, a small slice from the Wold Cottage stone, one from Sierra di Chaco, one from a Sienna stone, a fragment from the Rockwood stone, and a slice from the Rensselaer Co stone, all show with more or less clearness the like markings Of three microscope slides of the Fayette Co meteorite one shows them clearly, a second shows traces of them, the third not at all

A considerable number of the ground surfaces of meteoric stones in the Peabody Museum also show these markings For example, a triangular surface of a Weston stone, 8 or 10 centimetres to each side, exhibits them very well

These markings are such as we might expect if the forces which determine the crystallisation of the nickel-iron of the iron meteorites also dominated the structure of the rock-like formations of the stony meteorites and the distribution therein of the iron particles The relation of quartz crystals to the structure of graphic granite is naturally suggested by these meteorite markings.

H. A. NEWTON

THE LATE THOMAS DAVIES, F.G.S

MR. THOMAS DAVIES, who died on December 21 last, was born on December 29, 1837, in the neighbourhood of London, and was the son of Mr William Davies, F.G.S., of the Geological Department of the British Museum. His early education was of a very elementary character, and the period of his school-life was brief: finding town-life irksome, and yearning for freedom and adventure, he took to the sea at the age of fourteen, and during the next four years led a roving life, visiting China, India, and various parts of South America. He was then prevailed upon by his father to adopt a more settled mode of existence, and on the separation of the Department of Mineralogy from that of Geology was appointed in 1858 a third-class attendant at the British Museum under Prof Maskelyne, to whom the care of the minerals had been assigned, in the following year he added to his responsibilities by marriage

During the next nine years, save for a short interval when Dr Viktor von Lang was an assistant in the Department, Mr Davies was the sole helper of Mr Maskelyne in the arrangement and examination of the mineral collections, during this time Mr Maskelyne effected a thorough change in the classification and arrangement of the minerals, and in labelling with localities the large number of specimens that were without any descriptions except what could be traced out in old catalogues In this work, and in the cleaning and arranging some tons of specimens, of which many were entirely valueless, the patient and intelligent aid of "young Davies" alone rendered it possible to carry out the preliminary operations As the collection grew into orderly arrangement, the registration and labelling of specimens was entrusted to him by Mr Maskelyne It was thus that he gradually acquired an eye-knowledge of minerals which has rarely, if ever, been surpassed His perception of the peculiarities of a specimen was remarkably quick, while his remembrance of individual specimens was almost marvellous It was particularly in the habit, the locality, the associations and modes of occurrence of mineral species that he concentrated his interest, and to his knowledge in this direction his earlier training, under the eye of Mr Maskelyne, in the labelling of the minerals, accumulated in the cases and drawers of the collection, very largely contributed

In the early years of Mr Davies's museum life Mr Maskelyne was further engaged in the study of thin sections of meteorites, and initiated Mr Davies into a knowledge of the microscopic characters of rock-forming minerals, a mode of investigation then almost unknown In this direction his quickness of perception and excellence of memory had full scope for play, and Mr Davies soon became extremely skilful in the microscopic determination of minerals in rock-sections, and in the recognition of peculiarities of rock-structure Few practical petrologists approached him in this faculty

Nor did he neglect to improve his general education With this end in view he attended the evening classes at the Working Men's College in Great Ormond Street, and in the course of time acquired a knowledge of both French and German He was also familiar with plants and fossils, a knowledge largely derived from his father

His remarkable qualifications attracted the early attention of Mr. Maskelyne, and in 1862 were officially recognised in his promotion by the trustees from the grade of attendant to that of transcriber or junior assistant In 1880 he was promoted to the grade of first-class assistant By a remarkable coincidence his father, Mr William Davies, who had long been renowned for his large practical knowledge of important branches of palæontology, and especially of fossil fishes, and had likewise begun museum life as an attendant, obtained the same promotion on the same day. In the same year Mr Davies was awarded the balance of the proceeds of the Wollaston Fund by the Council of the Geological Society as a testimony of the value of his researches in mineralogy and lithology Still later, in 1889, the name of *Daviesite* was given to a new mineral "in honour of Mr. Thomas Davies, who has now been associated during upwards of thirty years with the British Museum Mineral Collection, and whose mineralogical experience and Breithauptian eye have ever been willingly placed at the service, not only of his colleagues, but of every one who has been brought into relationship with him"

He became a Fellow of the Geological Society in 1870, and was an early member of the Mineralogical Society of France.

His published work was not voluminous, it relates almost exclusively to the microscopic characters of the pre-Cambrian rocks. He contributed, however, the bulk of the articles on mineralogy and petrology for "Cassell's Encyclopædic Dictionary," and for some years edited the *Mineralogical Magazine*

Mr. Maskelyne, for whom he was right-hand man, and almost sole working helper during upwards of twenty years, looks back with fond regret on the uninterrupted happiness of their association According to my own experience of the last fifteen years, he was an excellent colleague, always cheerful, good-tempered, and kind-hearted, ever ready to help in any direction, however much it might interfere with the particular work he had immediately in hand At home he was an enthusiastic gardener, wet or fine, absolutely reckless of weather, he was at work from early sunrise, and could boast the possession of one of the best managed gardens in the neighbourhood His love of fresh air and the bustling east wind never left him, even after recovery from the long illness which two years ago had taken him to the verge of the grave, he did not hesitate to show the greatest contempt for the protection of an umbrella, and notwithstanding the remonstrances of his friends, might still be occasionally seen enjoying the beating of the wind and rain on his unprotected face

He was an Original Member of the Mineralogical Society, and Foreign Secretary for several years preceding his death

Mr Davies leaves a widow and nine children to mourn his loss L FLETCHER

NOTES

AT the last meeting of the Council of the Mineralogical Society, it was resolved to initiate a "Thomas Davies Memorial Fund" on behalf of the widow and children of the late Mr Thomas Davies, F G S, of the British Museum The following gentlemen have consented to act as an Executive Committee.—Prof. N. S Maskelyne, F R S (chairman), Dr Hugo Müller, F.R.S (treasurer), Mr H A Miers, F G S (secretary), Prof. T G Bonney, F R S, Mr L Fletcher, F R S, Dr Henry Hicks, F R S, W H Hudleston, F R S, Prof. J W Judd, F R.S, Mr F W Rudler, F G S, Mr. F Rutley, F G S, Rev Prof T Wiltshire, F G S, Dr Henry Woodward, F R S Subscriptions for the fund should be sent to Dr Hugo Müller, 13 Park Square East, Regent's Park, London, N W

AN extra meeting of the Chemical Society will be held on February 20, at 8 p.m., the anniversary of the death of Herman Kopp, when a lecture will be delivered by Prof T E Thorpe, F R.S Lord Playfair will be in the chair.

AN International Botanical Congress is to be held during the Columbian Exposition at Chicago Prof C. E Bessey will receive communications on the subject.

M P DUCHARTIE has been elected president, and M L Guignard first vice-president, of the Botanical Society of France for the year 1893

THE annual public meeting of the University College Chemical and Physical Society will be held at University College, Gower Street, on Friday, February 24. The chair will be taken at eight o'clock by Prof F. T. Roberts, and Prof Watson-Smith will deliver an address on diseases incident to work-people in chemical and other industries.

MR THOMAS BRYANT, president of the Royal College of Surgeons, delivered the Hunterian oration on Tuesday afternoon in the theatre of the college, in the presence of the Prince of Wales and the Duke of York and a large and distinguished company. Mr. Bryant began by thanking their Royal Highnesses for their presence on the special occasion of the centenary of the death of John Hunter, the great founder of scientific surgery. In the course of his oration Mr. Bryant said that the whole world of vegetable and animal life was Hunter's subject, but that his main objects were the improvement of surgery by the elucidation of pathology, the examination of the causes which determine any departure from the normal type, whether of form or function, and the study of the means which nature adopts for the healing of wounds and the repair of injuries It was one of his special merits that he raised surgery out of the position of a a poor art, based on empirical knowledge and practised too much as a trade, to establish it firmly as a high and elevating science, at the same time raising its practitioners in the social scale, and doing as much for medicine as for surgery, for he considered them inseparable He made the profession scientific by basing it upon the widest knowledge of the structure and functions of all living things, and educed therefrom laws and principles for the guidance of future generations in their study and treatment of disease in any of its forms This alone should render him worthy of the thanks of civilised mankind.

MR GEORGE MATHEWS WHIPPLE, whose death we briefly recorded last week, had done much solid and valuable work in various departments of physical science Among the subjects in which he was especially interested were wind force and wind velocities, and throughout the greater part of his life, as the *Times* has said in a brief sketch of his career, he was constantly carrying on experiments with a view to determine wind force and to find out what were the best instruments for securing accurate results. He improved the Kew pattern magnetic instruments, he designed, among other instruments, the apparatus for testing the dark shades of sextants, and at various periods he was associated with Captain Heaviside, Major Herschel, and General Walker, in carrying on pendulum experiments for the determination of the force of gravity The magnetic part of the report of the committee appointed by the Royal Society to investigate the Krakatoa eruption and the subsequent phenomena was prepared by Mr Whipple, and valuable papers were from time to time submitted by him to the Royal Society and the Royal Meteorological Society He was fifty years of age at the time of his death He entered the Kew Observatory in 1858, became magnetic assistant in 1862, and was appointed superintendent in 1876. This office is one of great and growing importance, and we trust that a capable successor may be found The Kew Observatory is the central standardising station of the Meteorological Office, and numerous magnetical observatories in other countries are similarly connected with it New instruments are tested there, and experiments are made, and it has now grown into an institution where the verification of scientific instruments of many kinds, including thermometers, sextants, telescopes, watches, and recently photographic lenses, is carried on on a large scale, as described in the annual report of the Kew committee to the Royal Society

THE Rev F O Morris died at Nunburnholme, in Yorkshire, on Friday last, at the age of eighty-two. He was well-known as a popular writer on science, and did much to create and foster interest in some branches of natural history, especially in ornithology Among his many books were "A History of British Birds," issued in six volumes from 1851 to 1857, and his "Natural History of the Nests and Eggs of British Birds," published in three volumes in 1853. In 1854 he was presented to the rectory of Nunburnholme, which he continued to hold until his death.

A DESTRUCTIVE earthquake has taken place in the island of Samothrace. All the buildings are said to have been destroyed. Renewed shocks, accompanied by loud subterranean rumblings, have also occurred at Zante.

ON Sunday a shock of earthquake was experienced in New Zealand. It caused little damage, but was felt in both the North

and South Islands, being most severe at Wellington and at Nelson

THE weather of the past week has been very stormy and damp in most parts of these islands, scarcely a day has passed without gales being reported On Friday, the 10th, the wind force was especially strong, on the north-east coast of Scotland and in the English Channel, and on Tuesday another deep depression had reached our northern coasts from off the Atlantic, accompanied by strong gales The United Kingdom was situated between two areas of high barometer readings, one of which lay over Scandinavia and the other over France and Spain With this distribution of pressure, the conditions were favourable to the passage of cyclonic disturbances within our area, and although the storms were not of exceptional violence in the southern districts, they were so relatively, as the winds have been peculiarly quiet during the last twelve months Temperature has been a little above the mean for the season, the daily maxima often exceeding 50°, but on Sunday the highest day readings were below 40° over the north-east of England, while a sharp frost occurred in the north of Scotland, the minimum temperature registering 20° On the continent the temperature has been much lower than in this country; at Haparanda, at the north of the Gulf of Bothnia, which lies in the area of the high barometric pressure over Scandinavia, a temperature of minus 37° was recorded on Friday and Saturday Rainfall has been of daily occurrence at most stations, although the amounts measured have generally been light, while hail and sleet have occurred in many places. With Tuesday's storm, however, the rainfall exceeded an inch on the west coasts of Ireland and Scotland By the *Weekly Weather Report* of the 11th instant it appears that the rainfall for that week was greatly in excess of the mean in the north and west of Scotland, and to a less extent in the east of Scotland, the north of Ireland, and the western parts of England Bright sunshine exceeded the mean in all districts, the greatest amounts, 32 to 38 per cent, being recorded in most parts of England

THE recent numbers of *Ciel et Terre* (Nos 21 23) contain interesting articles on ozone The observation of this element by meteorologists has been almost given up in most countries, owing chiefly to the difficulty of obtaining comparable results by the methods at present in use, although its importance for invalids and others as a purifier of the atmosphere is generally acknowledged And at a recent meeting of the Royal Meteorological Society, regret was expressed at the discontinuance of these observations D. A Van Bastelaer, in conjunction with the Royal Observatory of Brussels, maintained a system of ozone observations at 150 of the stations belonging to the Society of Public Medicine in Belgium during the years 1886–91, which is probably the most complete investigation into the subject which has been made The values found for the various stations are given in a tabular form, and M Van Bastelaer found that there are continual and sudden variations in the records from hour to hour, between morning and evening, and from one day to another, but that the mean values for any locality remain nearly constant. Isolated values are of no use, a long series of observations is necessary for any results of importance to be arrived at. The air at stations near the sea coast contained, as is usually supposed, the greatest amount of ozone

THE Indiana Academy of Science lately held at Indianapolis its eighth annual meeting, the president being Prof J. L. Campbell, of Wabash College, Crawfordsville, Ind. There was a large attendance, and no fewer than ninety-two papers had been prepared, most of which were read. The first volume of the Academy's Proceedings was distributed at the meeting.

THE *Kew Bulletin* continues, in the January number, its series of articles on the food grains of India, one of the subjects being Kangra Buckwheat (*Fagopyrum tataricum*, Gærtn, var. *himalaica*, Batalin) The typical plant is cultivated throughout the higher Himalayas, but more especially on the western extremity, and at altitudes from 8000 to 14,000 feet The yield in India cannot yet be estimated, but the *Bulletin* says there can be little doubt that the seeds are singularly rich in nutrient constituents This is confirmed by the conclusions of Prof Church with regard to a sample he has examined

THE January number of the *Kew Bulletin* contains also the fourth decade of new orchids, the fourth of "Decades Kewenses," papers on fruit growing at the Cape and the clove industry of Zanzibar, and miscellaneous notes

PROF R SHIMEK is now investigating the flora and the geology of Nicaragua, along the route of the canal, under commission from the State University of Iowa Dr Terracciano, of Rome, is about to renew his investigation of the flora of Erythrea, the Italian colony on the Red Sea Dr K. N Denkenbach is commissioned by the Natural History Society of St Petersburg to investigate the flora of the Black Sea

MR R THAXTER proposes in the *Botanical Gazette* the establishment of a new order of Schizomycetes, the Myxobacteriaceæ, somewhat intermediate in its characters between the typical Schizomycetes and the Myxomycetes It comprises the genus Chondromyces, placed by Berkeley, in his "Introduction to Cryptogamic Botany," under the Stilbacei, and two new genera, Myxobacter and Myxococcus The order consists of mobile rod-like organisms, multiplying by fission, secreting a gelatinous base, and forming pseudo plasmode like aggregations before passing into a more or less highly-developed cyst-producing resting state, in which the rods may become encysted in groups without modification, or may be converted into spore-masses

AT the meeting of the Royal Botanic Society on Saturday, one of the branches of the flowering stalk of *Fourcroya selloa* was shown from the Society's conservatory. This is a Mexican plant allied to the aloes, and like them it flowers only once during its life The plant, which has been in the conservatory for upwards of twenty years, late last autumn threw up a flower spike which in a very short time grew to a height of 30 feet, and, passing through the glass roof, rose for some feet into the open air It could not, of course, resist the frosts and fogs of winter. The flower-buds dropped unopened, when immediately from each node a number of young plants appeared This mode of reproduction is found in only a few varieties of plants, and is especially valuable in relation to the cultivation of Fourcroyas as a source of commercial vegetable fibre

THE Newcastle Literary and Philosophical Society will have no very pleasant associations with the memory of its hundredth anniversary, which was celebrated on Tuesday of last week During the following night the society's premises caught fire and were greatly damaged. Much injury was done to the library, where many most valuable books were destroyed.

THE fifth and sixth parts of the fifth volume of the *Internationales Archiv für Ethnographie* have been issued together in a single number It includes the second part of Dr W Svoboda's interesting study (in German) of the inhabitants of the Nicobar Islands; a paper (in French) by Désiré Pector on the volume by Dr Hyades and Dr Deniker (noticed some time ago in NATURE) on the ethnography of a part of Tierra del Fuego; a suggestive essay (in German) by Dr. T Achelis, on the psychological importance of ethnology; and the second part of Dr. Schmeltz's careful contributions (in German) to the

ethnography of Borneo. The first and last of these papers are admirably illustrated A valuable paper on the Ainos, by David MacRitchie, of Edinburgh, has been published as a supplement to the fourth volume of the *Archiv* This paper is accompanied by, and contains full descriptions of, a series of coloured reproductions of most interesting pictures of Aino life by Japanese artists, who have naturally a keener perception of the characteristics of their savage neighbours than can be attained by Western visitors Mr MacRitchie seeks to show that the Ainos display "unmistakable traces of a near descent, by at least one line of their ancestry, from the most crude form of humanity"

MESSRS SAMSON AND WALLIN, Stockholm, are about to issue what promises to be an important and interesting work, by F R Martin, on the Siberian Antiquities of the Bronze Age, preserved in the museum of Minousinsk. Nearly 900 objects in copper and bronze will be represented in the plates, which, according to the prospectus, are being prepared with the greatest care The antiquities of which these objects are selected specimens were collected in 1874 by M Nicolai Martianow from mounds in the steppes of the Upper Yenisei They are the finest provincial collection in the Russian Empire, and M Martin found much to interest him in classifying and photographing them The present volume will be the first of a series of works on the ethnography and archæology of Western Siberia by the same writer

THE third volume of "A Journal of American Ethnology and Archæology," edited by J Walter Fewkes, has been issued It contains an interesting "outline of the documentary history of the Zuñi tribe," by A F Bandelier, and "somatological observations on Indians of the south-west," by Dr H F C Ten Kate It is worth while to note that in Dr Ten Kate's opinion the study of physical anthropology among the North American Indians does not tend to demonstrate that their types are exclusively American It rather shows, he thinks, that they present only the characteristics of "the Mongolian or so called yellow races" "I do not mean,' he says, "that the American aborigines are Mongolians in the strict sense of the word, or that America has been populated from Asia Where the Indians came from I do not know, but my position is as follows —The American race is, somatologically speaking, not a type, but has characteristics which can only be called Mongoloid"

PROBABLY no living sportsman has shot more big game in South Africa than Mr F. C Selous, who for years was more at home in a waggon or a tent somewhere in the far countries of Africanderland than in the towns and settlements of the Cape Colony or the Transvaal. He has nearly completed an account of eleven years' sport and travel, which will be shortly published by Messrs Rowland, Ward and Co, of Piccadilly It will be fully illustrated, and will include a variety of general information on subjects of interest in connection with the latest development of South African exploration

MR. ELLIOT STOCK has published the third volume of "The Field Club," a magazine of general natural history for scientific and unscientific readers, edited by the Rev Theodore Wood. The volume contains many articles which are well fitted to awaken interest in various aspects of natural science

WE referred lately to Dr D G Brinton's opinion as to the relation between nervous diseases and civilisation As his view has been called in question by Dr Rockwell, he returns to the subject in *Science*, supporting his own conclusions by a reference to a paper contributed by Dr I C Rosse, professor of nervous diseases at the Georgia Medical College, to the *Journal of Nervous and Mental Disease* for July, 1891 In this paper Dr Rosse cites many authorities to prove that there is as much nervous disease at low as at higher stages of civilisation, and perhaps more In the district of Columbia, for example, the decedents among the coloured people from nervous diseases often exceed those of the white population by thirty-three per cent Dr Rosse is inclined to believe that a sudden change in the social habits and condition of any race, at any stage of advancement, will result in a prompt development of neurotic disease A high civilisation, which is stable, excites such a condition less than instability in lower grades

AT the meeting of the Field Naturalists' Club of Victoria in November a paper presenting a list of species of Victorian butterflies was communicated It had been prepared by Messrs F Spry and Ernest Anderson, and embodied the results of work carried on during many years The *Victorian Naturalist* says the paper was "received with great satisfaction, and will prove of extreme value to the Victorian lepidopterist"

MR H L CLARK records in *Science* what he calls "a bit of satisfactory evidence" as to the rate of speed in the flight of certain birds He thinks that this is often greatly exaggerated He was travelling lately on the Baltimore and Ohio Railway, up the valley of the Potomac, when he saw a great many wild ducks, which are admitted to be among the strongest flyers in America It so happened that, on rounding a sharp curve, the train flushed a pair of buffle-heads, which started up stream at full speed On watching them he found that, instead of their leaving the train behind, the train was actually beating them, and he is confident that their rate of speed was not equal to that of the train "We kept alongside of them," he says, "for nearly a minute before they turned back down stream Careful calculation showed that the train was running at about thirty seven miles per hour, so that the rate of speed for those wild ducks would be about thirty-six I hope that others may have some evidence on this question of speed in flight which will throw more light on the subject"

AN interesting illustration of the tendency of inorganic matter to simulate the forms seen in organic is afforded by some specimens of hæmatite from a mine in Lake Superior district It is described in the *American Geologist* as a fibrous red hæmatite, compact and tough-looking, and the radiating filaments or fibres towards their summits are seen to spread out like some frondescent vegetable growths It would seem that in process of increase these fibres, starting from different but slightly distant points, and having a tendency to expand, soon began to interfere with one another The line of contact, which became a plane as growth continued, is marked by a more or less distinct plane of separation This frondescent hæmatite, in addition, is pierced by a number of peculiar channels which seem to date from the time of development of the crystals It is noticed that these run, in general, perpendicular to the fibrous structure, and lie in or across the planes of contact of two oppositely spreading frondescent growths. These appear to mark in the first instance the vacancies left by the first contacts of overarching growths from opposite directions. These branches then interfered with the free circulation of air, and interrupted and permanently stopped the development of these fibres beneath the overspreading canopy

IT was shown by Ferraris some time ago (and the fact was of great practical importance) that by means of two simple alternating currents acting in fixed spirals, a rotating magnetic field could be produced, which by inductive action set in rotation a copper cylinder or other conducting body brought into the field. Also an iron cylinder, cut through so that the Foucault induction currents could not be formed, was rotated by virtue of so-called magnetic hysteresis. Further studies in this direction have been made by Signor Arno, using electric instead of magnetic forces, and a dielectric body instead of a magnetic

He thus succeeded in rotating a hollow cylinder of mica, or other insulating substance, hung by a silk fibre, in the space enclosed by four vertical curved copper plates, to which the requisite differences of potential were communicated. An account of these interesting experiments (described to the Accademia dei Lincei) will be found in the *Naturwissenschaftliche Rundschau*, No. 3, 1893.

Prof. R. C. Schiedt has been making some interesting observations on oysters, and at a recent meeting of the Philadelphia Academy of Natural Sciences Prof. Ryder reported on his behalf that oysters which had the right valve removed and were exposed to the light in this condition, in a living state for a fortnight or so, developed pigment over the whole of the epidermis of the exposed right mantle and on the upper exposed sides of the gills, so that the whole animal from this cause assumed a dark-brown colour. Animals so exposed not only attempted to reproduce the lost valve and hinge, but also partly succeeded in so doing, even re-establishing the insertion of the diminutive pedal muscle upon the inner face of the imperfectly reproduced right valve, which was deformed owing to the lack of support of the right mantle, because of the removal of the original right valve. As a consequence the right mantle was rolled up at the edge, and this deformation of the mantle was reflected in the attempted regeneration of the lost right valve. The pigment developed during exposure to light in the mantle and gills in oysters with the right valve removed, which were kept alive in the aquaria at Sea Isle City by Prof. Schiedt, was wholly confined to the epidermis as it normally is at the mantle border in the unmutilated animal in nature. The inference to be drawn from these facts is that the development of pigment in the mantle and gills was wholly and directly due to the abnormal and general stimulus of light over the exposed surface of the mantle and gills, due to removal of the right valve, and that the mantle border, the only pigmented portion of the animal, is pigmented because it is the only portion of the animal which is normally and constantly subjected to the stimulus of light.

Mr. D. Cleveland, of San Diego, California, contributes to *Science* an article in which he states some curious facts regarding the trap-door spider (*Mygale henzii*, Girard), which is widely diffused in California. Behind San Diego there are many hillocks about a foot in height and three or four feet in diameter. These hillocks are selected by the spiders, Mr. Cleveland suggests, because they afford excellent drainage and cannot be washed away by the winter rains. A suitable spot, which always consists of clay, adobe or stiff soil, having been chosen, the spider excavates a shaft varying from five to twelve inches in depth, and from one-half to one and a half inches in diameter. This is done by means of the sharp horns at the end of the spider's mandibles, which are its pick and shovel and mining tools. The earth is held between the mandibles and carried to the surface. When the shaft is of the required size, the spider smooths and glazes the wall with a fluid which is secreted by itself. Then the whole shaft is covered with a silken paper lining, spun from the animal's spinnarets. The door at the top of the shaft is made of several alternate layers of silk and earth, and is supplied with an elastic and ingenious hinge, and fits closely in a groove around the rim of the tube. This door simulates the surface on which it lies, and is distinguishable from it only by a careful scrutiny. The spider even glues earth and bits of small plants on the upper side of the trap-door, thus making it closely resemble the surrounding surface. The spider generally stations itself at the bottom of the tube. When, by tapping on the door, or by other means, a gentle vibration is caused, the spider runs to the top of its nest, raises the lid, and looks out and reconnoitres. If a small creature is seen, it is seized and devoured. If the invader is more formidable, the door is quickly closed, seized, and held down by the spider, so that much force is required to open it. Then the spider drops to the bottom of the shaft. When the door of the nest is removed, the spider can renew it five times—never more than that. From forty to fifty cream-coloured spiderlings are hatched from the yellow eggs at the bottom of the nest. When these have attained only a fraction of their full size—before they are half grown—the mother drives them out into the world to shift for themselves. After a brief period of uncertainty they begin active life by making nests, each for itself, generally close to "the old homestead," sometimes within a few inches of it. These nests are always shallow and slender, and are soon outgrown. When the spider attains its full size it constructs a larger nest.

An interesting paper concerning the supposed volatility of the element manganese is contributed by Prof. Lorenz and Dr. Heusler, of Gottingen, to the current number of the *Zeitschrift für Inorganische Chemie*. Although the melting point of the metal is known with tolerable certainty to be about 1800° – 1900°, much higher than that of iron, no information has yet been acquired concerning its boiling point. Profs. Lockyer and Chandler Roberts, however, so long ago as 1875 pointed out that the metal was volatile at the temperature of the oxy-hydrogen blowpipe; and M. Jordan, in a communication to the *Comptes Rendus* in the year 1878, reported that in the manufacture of highly manganiferous spiegeleisen near Marseilles, a deposit very rich in manganese was usually found in the cooler portions of the furnace. Moreover, M. Jordan stated that during the casting of ferro-manganese red flames are produced, from which a heavy fume is deposited containing a large percentage of manganese. M. Jordan subsequently heated ferro manganese to a white heat in a crucible in his laboratory, and ascertained that a diminution in the percentage of manganese actually occurred. These observations were considered somewhat surprising, inasmuch as the melting point of manganese is so high, in the neighbourhood of white heat, and it would appear that this volatility must be exhibited even at the melting point itself.

Prof. Lorenz and his colleague have therefore conducted a series of experiments with the view of ascertaining whether manganese is really volatile *per se*, or whether the volatility is due to the intermediate action of carbon monoxide (derived from the carbon usually present) in forming a volatile but dissociable compound of a nature similar to nickel- and iron carbonyl. It was first definitely proved that carbon monoxide does not combine with manganese below the temperature of 350°, a fact which M. Guntz has recently independently pointed out. Experiments were then made at higher temperatures, using a new form of combustion furnace, designed by Prof. Lorenz and fully described in the *Zeitschrift*, in which each individual burner is supplied with a blast capable of being regulated, the whole apparatus being equivalent to a row of blowpipes which will rapidly raise a thick porcelain tube up to a white heat. In the first series of these high temperature experiments coarsely powdered manganese containing seven per cent. of carbon was heated to whiteness in a glazed porcelain tube in a current of carbon dioxide, in order that nascent carbon monoxide might be produced in contact with manganese by the reduction of the carbon dioxide by the carbon present. After half-an-hour's heating the tube was allowed to cool in the stream of carbon dioxide and then broken, when it was found that a large quantity of the manganese had volatilised and condensed again further along the tube, in the form of a thick black deposit somewhat resembling zinc dust. Upon repeating the experiment with a current of carbon monoxide, a similar result was obtained. Hence manganese is certainly volatile in carbon monoxide. But it was afterwards found that equally good deposits of manganese dust were obtained when a current of

either hydrogen or nitrogen, neither of which combine with manganese, were employed It is therefore evident that manganese does not resemble iron and nickel in forming a volatile compound with carbon monoxide, but that the volatility is a property of the element itself, and is singularly manifested even at the temperature of the melting point

SOME of the more interesting captures recently made by the dredging staff of the Marine Biological Association at Plymouth are the Actinian *Chitonactis coronata*, the Nudibranchs *Berghia cærulescens* (new to Britain), *Amphorina cærulea*, and *Lamellidoris oblonga* in considerable numbers, and the handsomely marked rare spider-crab, *Stenorhynchus egyptius* The alga *Halosphæra viridis* has been present in all townettings since October; and *Noctiluca*, though in small numbers, is now generally present The breeding season of a large number of Invertebrata has already commenced, and the sea swarms with Copepod and Cirrhipede Nauplii, and with Polychæte larvæ Species of the following genera are breeding —The Hydroids *Halecium*, *Plumularia*, *Sertularella*, *Hydrallmania*, the Actinians *Chitonactis* and *Actinia*, the Nemertine *Lineus obscurus* (larva of Desor), *Phyllodoce maculata* and other Annelids, the Molluscs *Capulus hungaricus*, *Lamellaria*, *Buccinum*, *Purpura*, many Nudibranchs, and the Decapod Crustacea *Crangon*, *Pandalus*, and *Palæmon*, *Carcinus*, *Cancer*, and *Eurynome*

THE additions to the Zoological Society's Gardens during the past week include a Fallow Deer (*Dama vulgaris* ♂) European, presented by Mr B L Rose, a Great Eagle Owl (*Bubo maximus*) European, presented by Mr Adolphus Drucker; two Gold Pheasants (*Thaumalea picta* ♀ ♀) from China, presented by Miss Forster, nine Snow Buntings (*Plectrophanes nivalis*) British, presented by Mr T E Gunn, an Egyptian Cobra (*Naia haje*), two Hoary Snakes (*Coronella cana*), from Victoria West, Cape Colony, presented by the Rev G H R Fisk, C M Z.S., three European Pond Tortoises (*Emys europæa*) European, deposited, a King Snake (*Coluber getulus*) from North America, received in exchange.

OUR ASTRONOMICAL COLUMN

THE TOTAL SOLAR ECLIPSE OF APRIL 15–16, 1893 —The following particulars of the phenomena of the total solar eclipse of April 15–16, 1893, have been supplied to the Eclipse Committee by Mr A M W Downing, Superintendent of the *Nautical Almanac* office, for the use of the English observers at the eclipse stations to be occupied in Brazil and Africa —

Brazil. Longitude 38° 50′ W Latitude 3° 20′ S

		d h. m s.	Contact from N point	Contact from vertical	Sun's altitude
Eclipse begins	April	15 22 18 14	136° W	19° W	62°
Totality begins		15 23 40 51	Duration 4m. 43 1s		
Totality ends		15 23 45 34			
Eclipse ends		16 1 11 40	45° E	84° W	68°

Local mean times

Senegambia. Longitude 16° 30′ W Latitude 14° 15′ N.

		d. h m s	Contact from N point	Contact from vertical.	Sun's altitude
Eclipse begins	April	16 1 5 3	130° W	156° E	73°
Totality begins		16 2 27 59	Duration 4m. 12·3s

Eclipse ends		16 3 48 1	57° E	24° W.	35°

Local mean times.

REMARKABLE COMETS.—Bearing this title, Mr. Lynn has written a small book, in which he gives a short survey of the most interesting facts that have occurred in the history of cometary astronomy. As he remarks in the preface, the scope of the work is almost purely historical; but we are sure there are many who will peruse these few pages with great pleasure, for the author has brought together these facts and presented them to the reader in a concise and plain style We may mention that figures relating to elements of orbits, &c., are at a minimum, Mr Lynn simply restricting himself to bare accounts The author concludes by giving a list of the dates at which some of the comets may reappear, from which we make the following extract —

Date		Period in years.	
1893	Summer	6½	Finlay's Comet
1894	Winter	3⅓	Encke's ,,
1896	Spring	7½	Faye's ,,
,,	,,	7	Brook's ,,
1897	,,	6½	D'Arrest's ,,
,,	,,	5½	Swift's ,,
1898	Summer	5½	Winnecke's ,,
,,	Autumn	7	Wolf's ,,
1899	Spring	33¼	Comet of 1866
,,	Summer	13¾	Tuttle's Comet
,,	,,	7	Holmes's ,,

The comet of 1866, as many of our readers well know, is identical with the meteoric stream through which we pass in November, so we hope that we shall be visited by a fine display

COMET HOLMES (1892, III) —Comet Holmes seems to have become somewhat dimmed during the past week, but we nevertheless give the ephemeris for the benefit of those who wish to follow it a little longer

Ephemeris for 12h M T, Paris

1893	R A app h m s	Decl app h m s
Feb 16	2 7 37 9	+34 14 30
17	9 15 3	16 42

RELATIVE POSITIONS OF STARS IN CLUSTER χ PERSEI —Volume xxx part iv of the Transactions of the Royal Irish Society contains the results of the investigations of Sir Robert Ball and Mr. Arthur Rambaut, with respect to the relative positions of 223 stars in the cluster χ Persei as determined photographically. The instrument used throughout was a 15-inch silver on glass reflecting telescope, mounted according to Cook's standard equatorial pattern. For the adjustment of the plate (the size used here being 3¼ × 3¼) and mirror Dr. Johnstone Stoney's collimator was employed, this method ensuring the exact perpendicularity of the photographic plate to the axis of the collimator. The negatives were measured with an instrument made by the same firm, and after the same pattern as that used by Prof Pritchard, at Oxford, this instrument being supplied with the means of measuring either rectangular or polar coordinates, the former of which has been adopted here throughout In this memoir the authors treat in detail, by means of figures and formulæ, the equations for orientating the plate for measurement, for computing the differences in Right Ascension and Declination from the centre of the plate, for correcting the relative apparent positions of the stars for effects of separation, observation, nutation, and procession, &c. The measures here given have been obtained from one photograph taken with an exposure of ten minutes, the images under the microscope being susceptible "of very accurate measurement" That only

one negative has been employed is due, as the authors say, to pressure of other work and to necessary alterations in the instrument, but they hope to repeat the investigation next autumn In the table showing the positions, the authors compare their results with those of Vogel and Pihl, and they find that a small difference, depending on the adopted position of the fundamental star, is apparent between the former's declinations, while Pihl's right ascensions differ slightly, though systematically, this discrepancy being due very probably to the different methods of determining the parallels. The memoir concludes with a map showing the relative positions of the stars plotted direct from the x and y coordinates

L'ASTRONOMIE —The February number of this journal contains many articles of interest Prof Stanislas Meunier gives an account of a meteorite that fell in Algeria, this meteorite has proved to be of iron, containing as much as 91 32 per cent, and a polished surface, when treated with an acid, showed the well known Widmannstatten figures M Flammarion, in addition to an account of "Les Pierres Tombées du Ciel," with reference to "Les Anciens Volcans de la Lune," lately advocated by Prof Coakley in *Astronomy and Astrophysics*, gives the fourth out of six chapters dealing with the question, "Comment Arrivera la fin du Monde" M J Fényi, director of the Observatory of Kalocsa, gives an account of the enormous solar eruption (383,000 kilometres high) that occurred on October 3 last, while a short note on some curious appearances undergone by comet Swift includes six drawings by M Lorenzo Kropp, taken between March 18 and April 25, and the three photographs taken at the Lick Observatory by Mr Barnard, all of which indicate the results of tremendous actions, whether they be due to the influences of different forces, "attraction, repulsion, chaleur, électricité, or changements d'état, qui agissement sur ses astres gazeux dans leur voisinage du soleil" M Weinck of Prague describes the results of his examination of the Lick negatives with reference to the lunar crater Flammarion, and gives a drawing (which, by the way, can be well seen by half closing the eyes) of its surroundings, together with the three new craters. This number also includes a general summary of the meteorology of the preceding year, the results being given in diagrammatic form, bringing out clearly the diurnal and monthly changes

JUPITER'S FIFTH SATELLITE —Mr Barnard, who has been continuing his observations with respect to the fifth satellite of Jupiter, communicates the results he has obtained to the *Astronomical Journal* (Nos 285-86) The values of the elongation distances deduced from the measures at elongations are, for eastern elongation, 48″ 089 (± 0 061), and for western elongation, 47″ 621 (± 0 176), the probable errors of a single determination being ± 0″ 23 and ± 0″ 47 respectively These values are equivalent to the following distances —

E.	elongation	112,500 ± 143 miles
W	,,	111,412 ± 412 ,,

The values for the period he gives as

		h	m	s
September 10–October 21	P =	11	57	23·72
September 10–October 28	P =	11	57	23 30
September 10–November 20	P =	11	57	22 73

the mean, when proportional weights are applied, being—

11h. 57m. 23·06s

Among some other figures which Mr Barnard gives are —

Hourly motion	30° 111
Velocity in orbit	16·4 miles per second
Equatorial Hor. Par	21° 51′
Distance from surface of Jupiter	67,000 miles (about)

While working at this satellite he has also been led to measure the equatorial and polar diameters of Jupiter himself, and the following numbers show the values he has deduced, the observations being made through smoked glass :—

Equatorial diameter	89,790 ± 65 miles
Polar ,,	84,300 ± 80 miles

GEOGRAPHICAL NOTES

THE *Times* Berlin correspondent furnishes some interesting notes of Dr. Baumann's recent journeys in the region of the Nile sources, which confirm Mr Stanley's identification of the Mountains of the Moon In Urundi the kings were supposed to be lineal descendants of the moon, and the white traveller was hailed as being the returned ghost of a lately-deceased chief On September 11 the expedition crossed the Akenyaru, which is not, as supposed, a lake, but a river, though the name "Nyanza" is often applied to it Dr Baumann also discovered that the so called Lake Mworengo is in reality a river which flows into the Akenyaru, and came to the conclusion that there was no extensive sheet of water in Ruanda or North Urundi. On September 19 Dr Baumann arrived at the source of the Kagera (Alexandra Nile), which rises at the foot of the precipitous and wooded hills which form the watershed between the basins of Rufizi and the Kagera This mountain chain is known to the natives by the name of the "Mountains of the Moon," and is held in peculiar reverence by them Here Dr Baumann maintains the real source of the Nile to be, for if "it be acknowledged that the Kagera is the chief feeder of the Victoria Nyanza, it follows that the headwaters of the Nile can be none other than those of the Kagera itself in the Mountains of the Moon in Urundi, within the boundaries of German East Africa"

THE often-discussed scheme of an expedition to the North Pole by way of Franz Josef Land has been revived by Mr F. G Jackson, who proposes to lead an expedition next summer, if the means for equipping a ship are forthcoming Mr. Jackson's plan is to travel with a small party, and establish a chain of depots northward from the most northerly accessible landing-place in Franz Josef Land He would remain during winter in the most advanced post, and push on each summer with dog sledges, until the pole is reached The plan rests on the hypothesis of Franz Josef Land extending to the pole, just as Dr Nansen's rests on the hypothesis of a transpolar current, but the evidence of the great extension of the land is not very satisfactory Mr Jackson's previous Arctic experience is not stated, nor is there any indication given as to whether he intends to travel at his own expense or to appeal for pecuniary help

THE British South African Company have reserved the Zimbabwe Ruins and the area within a radius of one mile from the top of Zimbabwe Hill for archæological and scientific purposes, and no settlements, farms, or mines will be permitted within that radius

A BEAUTIFULLY illustrated report on the regulation of Swiss torrents, by the late M de Salis, has recently been published by the Swiss Government The natural erosion and surface change which go on at the present day so rapidly among the steep slopes of a mountainous country as to be frequently cataclysmic in their intensity, have to be avoided or endured in inhabited regions A frequent source of floods is the damming up of a large river by the mud and stones brought down by a freshet in a small tributary The method of combating this effect is to build a succession of weirs, and cut a parallel canal so that the sediment is caught and the overflow regulated before the escaping water reaches the main valley.

MR. MACKINDER'S fourth Royal Geographical Society's educational lecture, delivered last week, dealt with Central Asian trade- and travel-routes, under the title of "The Gates of India and China."

TWENTY YEARS IN ZAMBESIA.

MR F C SELOUS, the famous hunter and explorer of South Central Africa, gave a summary of his travels to the Royal Geographical Society on Monday evening His address was illustrated by an exhibition of unusual interest in the tea-room, where a large collection of stuffed specimens of the characteristic African mammalian fauna was arranged Photographs and various objects illustrative of the rapid development of Mashonaland since the Chartered Company took possession were also shown.

Mr. Selous commenced his African wanderings in 1871, and except for occasional visits to England he has travelled and traded in that continent ever since In 1872 he and some companions penetrated into Matabeleland to hunt elephants, and had an amusing interview with the chief, Lo-Bengula. Although at that time not an explorer in the scientific sense, the accurate memory of his early wanderings over the country enabled Mr.

Selous to successfully guide the Pioneer Force of the Chartered Company in 1890, when they took possession of Mashonaland

With regard to the health of Zambesia he says —"Owing to severe exposure to wet and cold during several days and nights, in the early part of 1872, I got an attack of fever and ague in Griqualand so that I was handicapped before starting for the interior This fever and ague was exactly what I have seen people get on the high plateau of Mashonaland, during the last few years, from similar exposure to rain and cold It took me some time to shake off, and was still in my system when I reached Matabeleland, but the attacks only came on when I halted anywhere for a few days During November and December, 1872, hunting down in the low hot country towards the Zambesi, I was again very much exposed to wet, and on several occasions lay out all night long, without any shelter, drenched through with such heavy rain that it put out the largest fire and converted hard ground into a swamp I naturally again got soaked with fever poison, but as long as I remained hunting the disease did not show itself Directly I got back to Bulawayo it broke out, and during a month or so I had several sharp attacks By that time, however, my sound constitution had choked all the fever germs, and from that day until in 1878, when very severe exposure in Central Africa once more filled me up with malarial poison, I do not remember ever to have had one single hour's illness, or to have taken one drop of medicine The life I led was, however, if a very hard, at any rate, in many respects, a very healthy one, for the most part I ate nothing but meat and Mashona rice, and drank nothing but tea, usually without milk and sugar—not because I like it so, but because those adjuncts were unobtainable"

North of the Zambesi Mr Selous made several journeys among the Batongas, and spent a wretched rainy season, almost without equipment, on the Manica table land After the rains the country looked charming The young grass, thanks to the recent heavy rain, had shot up one foot or eighteen inches in height over hill and dale, every tree and shrub was in full leaf, and everything looked green, and fresh, and smiling Many of the shrubs on the edge of the hills bore sweet smelling flowers, and, as on all the plateaus of the interior of Africa, small but beautiful ground-flowers were very abundant

Interesting observations were made on some of the northern rivers The curious phenomenon of the steady rise of the waters of the Chobe and Machabi—an outlet of the Okavango—was observed from the first week in June until the last week in September, when they commenced to recede That the Okavango and the Upper Kwando are connected on their upper courses, there can be little doubt, as the waters of the Machabi went on rising suddenly *pari passu* with the Chobe, until the end of September, when both commenced to recede simultaneously

The explanation of this remarkable phenomenon is difficult, as there are no snow mountains at the sources of the Kwando and Okavango rivers and the Zambesi, which rises in the same latitude, decreases steadily in volume from day to day during the dry season like almost all other rivers in South Central Africa Besides the channels which still become annually filled with water from the overflow of the Chobe and Okavango river systems, there are many others which are now quite dry, but in which the natives say they once used to travel in canoes

From 1882 the journeys acquired additional geographical importance, and Mr Selous proceeded to rectify the maps of Mashonaland laid down by earlier travellers, taking constant compass bearings, sketching the course of rivers, and fixing the position of the junction of tributaries. The value of this work was made manifest in a magnificent large scale map of the country, drawn as well as surveyed by Mr. Selous, which was used to illustrate the lecture It would be impossible, without practically reproducing the whole address, to do justice to the immense variety and solid value of the contributions to African geography made by this most energetic of pioneers, or to the thrilling adventures, the recital of which was listened to with breathless attention and greeted with the heartiest applause With the exception of a treacherous night attack made upon his camp by the Mashuku-sumbwe, led by a few rebel Marotse, in 1888, he had never had any other serious trouble with the natives During his twenty years' wanderings he went amongst many tribes who had never previously seen a white man, and he was always absolutely in their power, as he seldom had more than from five to ten native servants, none of whom were ever armed.

THE DISTRIBUTION OF POWER BY ELECTRICITY FROM A CENTRAL GENERATING STATION

ON Friday evening, the 3rd inst, Mr A Siemens delivered at the Royal Institution an interesting lecture on the ways in which science is applied to practice In the course of the lecture he made the following remarks on the distribution of power by electricity from a central generating station —

Before entering further into this, let me remind you that the earliest magneto-electric machines were used nearly sixty years ago for the production of power I will mention only Jacobi's electric launch of 1835 as an example It must, therefore, be considered altogether erroneous to ascribe the invention of the transmission of power to an accident at the Vienna Exhibition in 1873, when, it is said, an attendant placed some stray wires into the terminals of a dynamo machine, it began to turn, and the transmission of power was first demonstrated As a matter of fact, Sir Wm Siemens once informed me, that his brother Werner was led to the discovery of the dynamo electric principle by the consideration that an electro-magnetic machine behaved like a magneto electric machine, when a current of electricity was sent into it, viz both turn round and give out power It was, of course, well known that a magneto electric machine produces a current of electricity, when turned by mechanical power, and Werner concluded that an electro magnetic machine would behave in the same manner We all know that he was right, but I relate this circumstance only as a further proof that the generation of power by electric currents has been a well-known fact long previous to the Vienna Exhibition

Another well-known instance of transmission of power to a distance is furnished by the magneto-electric ABC telegraph instruments, where the motion at the sending end supplies the currents necessary to move the indicator at the receiving station

As an illustration of the distribution of power by electricity, I will briefly describe some radical alterations that have been made at the works of Messrs Siemens Brothers and Co, by the introduction of electric motors in the place of steam engines

[A diagram on the wall showed in outline the various buildings in which work of different kinds is carried on with the help of different machines]

Electric motors are supplying the power, sometimes by driving shafting to which a group of tools is connected by belting, and sometimes by being coupled direct to the moving mechanism Each section of the works has its own meter, measuring the energy that is used there, and all of them are connected by underground cables to a central station, where three sets of engines and dynamos generate the electric current for all purposes There are two Willans and one Belliss steam engines, each of 300 horse-power, coupled direct to the dynamos, and running at a speed of 350 revolutions per minute Room is left for a fourth set, but including some auxiliary pumps and the switchboards for controlling the dynamos and for distributing the current, the whole space occupied by 1200 horse-power measures only 32 × 42 feet Close by are the condensers and three high-pressure boilers, which have replaced some low pressure ones formerly used for some steam engines driving the machinery in the nearest building

The advantages that have been secured by the introduction of electric motors may be briefly stated under the following heads —

1 Various valuable spaces formerly occupied by steam engines and boilers have been made available for the extension of workshops, and these are indicated on the diagram by shading.

2 By abolishing to a great extent the mechanical transmission of power a considerable saving is effected in motive power, which is especially noticeable at times when part only of the machinery is in use

3 As the electric motors take only as much current as is actually required for the work they are doing, a further saving is effected, and at the same time the facility with which the speed of the motors can be altered without their interfering with each other presents a feature that is absent from mechanical transmission

4. The big steam engines being compound and condensing, produce a horse-power with a smaller consumption of fuel than the small high-pressure steam engines scattered throughout the works.

5 The numerous attendants of the old steam engines and boilers have mostly been transferred to other work, only a few of them are required at the central station, and one or two men can easily look after all the electric motors used in the various parts of the works

Elsewhere equally favourable results have been obtained by the introduction of electrical distribution of power, and in this respect I beg to refer you to a paper read before the German Institution of Civil Engineers by Mr E Hartmann in April of last year, and to a paper read by Mr Castermans before the Society of Engineers in Liège, in August last, in which he compares in detail various methods of transmission of power, of which the electrical one was adopted for a new small arms factory.

We may therefore take it for granted that the advantages alluded to above have not resulted from local circumstances at Woolwich, but that they can be realised anywhere by the adoption of the electric current for distributing power from a central station

At first sight this result appears to be of interest only to the manufacturer, but the development of this idea may lead to far-reaching consequences, when we consider that cheap power is one of the most important requisites for cheap production

While power was generated by steam engines the cost of producing one-horse power varied a good deal in the different parts, and the various owners could not have obtained their power on equal terms, those possessing the largest steam engines having a distinct advantage This inequality is done away with altogether when the power is distributed by electricity, as the current can be supplied for large or small powers at the same rate per Board of Trade unit It is therefore clear that the establishment of central stations for the generation of electricity on a large scale will bring about the possibility of small works competing with large works in quite a number of trades where cheap power is the first consideration

Another circumstance favouring small works is the diminution of capital outlay brought about by the employment of electric motors Not only are the motors cheaper than boilers and steam engines of corresponding power would be, but the outlay for belting and shafts is saved, and the structure of the building need not be as substantial as is necessary where belts and shafting have to be supported by it A commencement has already been made in this direction by the starting of electric light stations, where the owners do all in their power to encourage the use of the current in motors, in order to keep the machinery at their central station more uniformly at work. The introduction of electricity as motive power will apparently present a strong contrast to the effect steam has had on the development of industries for the reasons already stated, and in addition there are many cases where the erection of boilers and steam engines, or even of gas engines, would be inadmissible on account of want of space or of the nuisances that are inseparable from them Motive power will therefore be available in a number of instances where up to the present time no mechanical power could be used, but the work had to be done by manual labour or not at all.

You may have noticed that I have confined my remarks hitherto to the case of distributing electricity over a limited area, but that I have not yet discussed the question of transmitting power to a great distance

Theoretically we have been told over and over again that the motive power of the future will be supplied by waterfalls, and that their power can be made available over large areas by means of electric currents. As a prominent example the installation is constantly mentioned by which the power of a turbine at Lauffen was transmitted over a distance of 110 statute miles to the Frankfurt Exhibition with an efficiency of 75 per cent. No doubt this result is very gratifying from a purely scientific point of view, but unfortunately in practical life only commercially successful applications of science will have a lasting influence, and in this respect the Lauffen installation left much to be desired. On the one hand science tells us that the section of the conductor can be diminished as the pressure of electricity is increased, and it appears to be only necessary to construct apparatus for generating electricity at a sufficiently high pressure so as to reduce the cost of a long conductor to reasonable limits. On the other hand, experience shows that at these high potentials the insulation of the electric current becomes a most difficult problem, and for practical purposes difficulty means an increased outlay of money.

MAGNETICAL AND METEOROLOGICAL OBSERVATIONS MADE AT THE GOVERNMENT OBSERVATORY, BOMBAY, 1890, WITH AN APPENDIX

THIS volume, we are informed, is the thirtieth of the series of "Bombay Magnetical and Meteorological Observations," extending the previous record from 1845 to 1889, up to 1890 At this well-organized observatory, under the direction of Mr Charles Chambers, continuous registration of the different magnetical and meteorological elements is maintained by means of automatic recording instruments, of which there are five sets, the magnetographs (three), the barograph, the thermograph, the pluviograph, and the anemograph, all being photographic records excepting that of the anemograph, which is mechanical In addition eye observations are also made, including the usual meteorological observations of weather and other phenomena Daily values for 1890 are given of atmospheric pressure, temperature of the air, rainfall, wind and cloud, with some further discussion of the anemometric results, five day means of meteorological elements are also given In the magnetic section is found observations of absolute horizontal force, magnetic declination and dip, at short intervals throughout the year And in the appendix is contained a collection of the monthly values of declination and horizontal force from 1868 to 1890, accompanied by a discussion of the secular changes of these elements In regard to declination the results show the eastern magnetic declination to have increased during the early years of the series, arriving at a maximum at about the middle of the period, and decreasing in the later years Taking the annual values of declination to be represented by the formula $\delta = at^2 + bt + c$, it is found that the maximum easterly declination occurred in 1880, with value 0° 57′ 17″ This actual observation of the turning-point at this place, in the long cycle of change, is very interesting The horizontal force values are similarly discussed, but in this case the values are generally progressive There is no discussion of diurnal inequalities, but these were elaborately treated in a previous volume Magnetic observatories in tropical and southern regions are valuable Many exist in Europe with others scattered over different parts of the northern hemisphere, generally publishing with regularity their results, but there is a want of similar establishments in southern regions There are magnetic observatories at Batavia, Mauritius, and Melbourne, but we do not get from them all that might be desired England possesses no regularly maintained southern establishment of this kind A magnetic observatory existed many years ago at the Cape of Good Hope, which, long since destroyed, we believe, by fire, was never again reorganized, which was unfortunate The attention of the Magnetic Committee of the British Association was several years ago drawn to the question of re establishing the Cape Magnetic Observatory, and in the Report of the Committee for the year 1891 it is stated that a representation had been made to the Admiralty as to the desirability of so doing An efficient magnetic observatory in such a position, with regular publication of the results, would provide information of great value for the discussion of various questions in magnetic phenomena that now arise. It would be well also if the study of earth currents were taken up at some of the magnetic observatories in different parts of the world by continuous photographic registration thereof, for the better elucidation of the physical relation that may exist between magnetic and earth current variations, in regard to which our knowledge seems at present to be so imperfect

BACTERIA AND BEER

THE examination of water for micro-organisms since the publication by Koch in 1881 of his beautiful process of gelatine-plate cultures has come more and more into general use, as the public has gradually become cognisant of its value for hygienic and practical purposes But whilst affording much valuable information on many subjects, Hansen has pointed out, as far back as 1888, that as applied to the examination of waters for brewing purposes it cannot be considered wholly satisfactory Working on lines suggested by Hansen, Holm has recently published a paper, "Analyses biologiques et zymotechniques de l'eau destinée aux brasseries" (*Compte-rendu des travaux du laboratoire de Carlsberg*, vol iii, Copenhagen, 1892), in which he describes a large number of investigations on brewing waters examined by Hansen's method, and in which the relative merit for brewing

purposes of Koch's and Hansen's processes is also discussed It is obvious that the organisms to be feared in a brewery are those which will flourish in wort or beer, and that the mere knowledge of the number of bacteria in any given water as revealed by gelatine plate cultures is but of little use Hence Hansen and his pupils reject for such examinations gelatine-peptone, substituting sterilised wort and beer as a culture material. An interesting table is given showing the different bacteriological results obtained in the use of gelatine-peptone, gelatine to which wort had been added, wort alone, and beer For example, whereas a particular brewing-water yielded by gelatine-peptone about 8000 colonies per c.c., the majority of which were bacteria, gelatine mixed with wort gave about 14, all being moulds, in wort 5 4 were found, consisting of bacteria and moulds, whilst sterilised beer gave only 0 8 for the c c, and only moulds Holm points out that to estimate the value of a water for brewing purposes a note should also be made of the rate at which the organisms develop in the wort or beer, for should signs of growth only declare themselves after four or five days in the laboratory under favourable conditions of temperature and in the absence of competing forms, it is not unnatural to expect that their vitality, under the more rigorous conditions imposed during brewing operations, would be so far impaired that their development, if taking place at all, would only be accomplished with great difficulty Although instances occurred in which even after the lapse of seven days growths first made their appearance, yet in the majority of cases the incubation of the wort-flasks for one week was sufficient Holm is of opinion that the use of other culture materials besides wort is unnecessary, as all the organisms which successfully develop in beer can also grow in wort Moreover, it was found that in the process of sterilisation to which the beer was submitted a considerable proportion of its alcohol was lost, thus diminishing its natural bactericidal properties A beer containing 5 to 6 per cent of alcohol, after sterilisation, had this reduced to 2 8 per cent, although it even then proved a very unfavourable medium for the development of ordinary water bacteria As a practical outcome of his experiments Holm emphasises the necessity of a careful selection of the site for the erection of the water reservoir attached to a brewery The reservoirs of the old brewery at Carlsberg are placed in the immediate vicinity of the storehouses for grain and malt, consequently in this water a far larger number of moulds were met with than in the water examined from differently situated reservoirs supplying the laboratory and another brewery But although moulds usually predominate, yet they are not so much to be feared as the bacteria, more especially those which are found in the fermentation chamber, for although they are unable to assert themselves to any considerable extent in the beer preserved in the store cellar, yet when it is drawn off and thus aerated, and the temperature raised by its transference to bottles or small casks, these organisms can develop with an astonishing rapidity, and produce great mischief

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—Dr. Shore, of St John's College, late Examiner in Physiology, has been elected a member of the Special Board for Medicine, Dr. A Macalister, F R S, St John's, has been appointed an elector to the Professorship of Chemistry; Dr Ferrers, F R S., Master of Gonville and Caius, an elector to the Plumian Professorship of Astronomy, Prof. Newton, F R.S., Magdalene, an elector to the Professorship of Anatomy; Dr. Phear, Master of Emmanuel, an elector to the Professorship of Botany, Dr. R D Roberts, Clare, an elector to the Woodwardian Professorship of Geology, Mr P. T Main, St. John's, an elector to the Jacksonian Professorship of Chemistry, &c.; Mr. R. T. Glazebrook, F.R.S., Trinity, an elector to the Professorship of Mineralogy; Mr F Darwin, F R S, Reader in Botany, an elector to the Professorship of Zoology and Comparative Anatomy; Mr W. D Niven, F.R S, Trinity, an elector to the Cavendish Professorship of Physics, Dr Phear, an elector to the Professorship of Mechanism; Prof. Liveing, F R S, St John's, an elector to the Downing Professorship of Medicine; Dr P. H. Pye-Smith, F R.S, an elector to the Professorship of Physiology; and Sir G. M. Humphry, F.R.S., an elector to the Professorship of Pathology

SCIENTIFIC SERIALS.

American Journal of Science, February —Isothermals, isopiestics, and isometrics relative to viscosity, by C Barus The substance experimented upon was marine glue, and its viscosity at different pressures and temperatures was measured by a transpiration method, the substance being forced through steel tubes 10 cm long and 0 5 to 1 cm in diameter under pressures as high as 2000 atmospheres It was found that in proportion as the viscosity of a body increases with fall of temperature, its isothermal rate of increase with pressure also increases. Speaking approximately, the rate at which viscosity increases with pressure at any temperature is proportional to the initial viscosity at that temperature, and, conversely, the rate of decrease with temperature is proportional to the actual temperature and independent of the pressure An interesting result is that in high pressure phenomena at least 200 atmospheres must be allowed per degree Centigrade, in order that there may be no change of viscosity —"Potential," a Bernoullian term, by Geo F Becker —Datolite from Loughboro, Ontario, by L. V Pirsson —A new machine for cutting and grinding thin sections of rocks and minerals, by G H Williams —Stannite and some of the alteration products from the Black Hills, S D, by W. P Headden —Occurrence of hematite and martite iron ores in Mexico, by R. T Hill, with notes on the associated igneous rocks, by W Cross —Cæsium lead and potassium-lead halides, by N L Wells.—Ceratops beds of Converse County, Wyoming, by J B Hatcher — Use of planes and knife-edges in pendulums for gravity measurements, by T C Mendenhall. The employment of a pendulum to which the plane is attached instead of the knife-edge presents several advantages The plane may be accurately adjusted at right angles to the rod by simple optical methods A pendulum carrying a plane instead of a knife-edge is vastly less liable to injury, and the knife-edge being no longer an integral part of the vibrating mass can be reground or replaced at will The length of the pendulum is more capable of accurate determination, since the error introduced by the yielding of the edge under pressure is eliminated The disadvantage due to the uncertain position of the axis of oscillation can be mechanically got rid of by a proper construction of the raising and lowering apparatus, and experiment shows that the period in the course of twelve sets of swings of an hour each does not vary by as much as one part in a million The best angle for the knife edge was found to be about 130°, the material used being agate —Preliminary note on the colours of cloudy condensation, by C Barus If saturated steam is allowed to pass suddenly from a higher to a lower temperature in uniformly temperatured, uniformly dusty air, a succession of colours is seen by transmitted white light which, taken in inverse order, are absolutely identical with the colours of Newton's rings of the first two orders.—Lines of structure in the Winnebago Co meteorites and in other meteorites, by H. A Newton (reprinted in this issue) —Preliminary note of a new meteorite from Japan, by Henry A Ward —Restoration of Anchisaurus, by O. C Marsh (see Note, p. 349).

American Journal of Mathematics, vol. xiv. No 4 (Baltimore, 1892) —The main object of the note on the use of supplementary curves in isogonal transformation, by R. A. Harris (pp. 291–300), is to show how the problem of representing one plane conformably upon another, using any real function of the variable, may be made to depend upon the problem of constructing supplementary curves from given tracings of the corresponding principal curves. It is well illustrated by four carefully drawn figures In her memoir (pp 301–325) on the higher singularities of plane curves, Miss C. A. Scott goes over ground to some extent previously occupied by Profs Cayley and H. J S Smith in writing on the same subject (*cf* also papers by Brill and Nother in the *Math. Annalen*, vols. ix. xvi. xxiii) Nother's results are presented in analytical form, "involving no dependence on geometrical ideas even when geometrical terms are used." The author brings out his results more clearly by making use of Dr Hirst's method of quadric inversion. The text is accompanied by twenty-seven drawings of curves. Mr. W. H. Metzler, writing on the roots of matrices (pp 326–377), employs a modification of Dr. Forsyth's method of proving Cayley's "identical equation" ("Messr of Mathematics," vol. xiii.) to prove Sylvester's law of latency and Sylvester's theorems. He also investigates the existence of roots of matrices for different indices, and in particular the roots of nilpotent matrices. A

careful analysis of the contents is prefixed to the memoir Dr F N Cole (pp 378–388) discusses the simple groups from order 201 to order 500, and arrives at the conclusion that "the possible orders of simple groups of compound order between 201 and 500 are reduced to 360 and 432" The volume closes with a note (p. 389) by M M. D'Ocagne, correcting a slight mistake in a memoir by him in the 1888 volume, entitled "Sur certaines courbes," and the title page and index

SOCIETIES AND ACADEMIES

LONDON

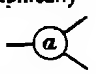
Royal Society, February 2 —"On a Meteoric Stone found at Makariwa, near Invercargill, New Zealand" By G H F. Ulrich, Professor of Mining and Mineralogy in the University of Dunedin, N Z Communicated by Prof J W Judd, F R S

The specimen described in this memoir was found in the year 1879 in a bed of clay, which was cut through in making a railway at Invercargill, near the southern end of the Middle Island of New Zealand Originally, this meteorite appears to have been about the size of a man's fist, and to have weighed four or five pounds, but it was broken up, and only a few small fragments have been preserved The stone evidently consisted originally of an intimate admixture of metallic matter (nickel-iron) and of stony material, but much of the metallic portion has undergone oxidation Microscopic examination of thin sections shows that the stony portion, which is beautifully chondritic in structure, contains olivine, enstatite, a glass, and probably also magnetite, and through these stony materials the nickel-iron and troilite are distributed The specific gravity of portions of the stone was found to vary between 3 31 and 3 54, owing to the unequal distribution of the metallic particles A partial chemical examination of this meteorite was made by the author and Mr James Allen, but the complete analysis has been undertaken by Mr. L. Fletcher, F.R.S, of the British Museum The analysis, which when finished will be communicated to this Society, has gone so far as to show that the percentage mineral composition of the Makariwa meteorite may be expressed approximately by the following numbers nickel-iron 1, oxides of nickel and iron 10, troilite 6, enstatite 39, olivine 44.

Physical Society, January 27 —Walter Baily, Vice President, in the chair —Prof. S P Thompson, F R S, made a communication on Japanese magic mirrors, and exhibited numerous specimens showing the magic properties. Referring to the theory of the subject, he said the one now generally accepted was that proved by Profs. Ayrton and Perry in 1878, who showed that the patterns seen on the screen were due to differences in curvature of the surface The experiments he now brought forward fully confirmed their views. Brewster had maintained that the effects were due to differences of texture in the surfaces causing differences in absorption or polarisation, but the fact that the character of the reflected image depended on the convergency or divergency of the light, and on the position of the screen, showed this view to be untenable Another proof of the differing curvature theory was then given by covering a Japanese mirror with a card having a small hole in it. On moving the card about, the disc of light reflected from the exposed portion varied in size, showing that the curvatures of portions of the surfaces were not the same. The same fact was proved by a small spherometer, and also by reflecting the light passing through a coarse grating from the mirror, the lines being shown distorted. To put the matter to a test demanded by Brewster, he had a cast taken from a mirror by his assistant, Mr. Rousseau; this had been metallised, silvered, and polished, and now gave unmistakable evidence of the pattern reflected from the original. The true explanation of how the inequalities of curvature were brought about during manufacture had also been given by Profs. Ayrton and Perry, but there were some questions of detail on which difference of opinion might exist. The late Prof. Govi had noticed that warming a mirror altered its possibilities. A thick mirror which gave no pattern whilst cold developed one on being heated, was shown to the meeting. Prof. Thompson also showed that a glass mirror having a pattern cut on the back developed magic properties when the mirror was bent. When made convex the reflected pattern was dark on a light ground, and when made concave, light on a dark ground. Warming ordinary mirror-glass by a heater whose surface was cut to a pattern gave similar effects. Very thick glasses could be affected in this way On passing a spirit lamp behind a strip of mirror, a dark band could be caused to pass along the screen illuminated by light reflected from the mirror By writing on lead foil and pressing the foil against a glass mirror by a heater, the writing was caused to appear on the screen Prof Thompson had also found that Japanese mirrors which are not "magic" when imported, could be made so by bending them mechanically so as to make them more convex In conclusion, he showed a large mirror 15″ × 11″, the reflection from which showed the prominent parts of the pattern on its back with the exception of two conspicuous knobs, these knobs gave no indication of their existence Prof Ayrton said the simple mechanical production of the magic property described by Prof Thompson led him to think that some experiments on "seeing by electricity" by the aid of selenium cells which Prof Perry and himself made some years ago, might lead to some result if repeated with thinner reflectors Speaking of the effect of scratching the back of a Japanese mirror, he pointed out that if metal be removed by pressure a bright image was seen, whilst if removed chemically a dark image resulted. Since the original paper on the subject was written he had been led to modify his views as to the effect of amalgamation, for some time ago he showed the society how brass bars were bent if one edge be amalgamated, thus proving that enormous forces were developed He now regarded amalgamation as an important part of the manufacture Mr Trotter inquired if it had been proved that there was no difference in the metal in the thick and thin parts? One would expect the thin parts to be harder and polished away less. After some remarks by Mr. J W Kearton and Major Rawson, Prof Thompson said the magic effects produced by heating the back of a glass mirror remained for a short time after the heater was removed The question of whether differences in hardness of the thick and thin parts of a mirror were of consequence in the production of the magic property had been tested by using sheets of brass thickened by pieces soldered to the back as mirrors, and found to be unimportant. Prof Ayrton also described an experiment pointing to the same conclusion —Mr W F Stanley read a paper on the functions of the retina—(1.) The Perception of Colour Referring to Young's three nerve theory of colour-sensation, the author said Prof Rutherford had pointed out that there was no necessity to assume that different nerves conveyed different colour-sensations, for as a telephone wire would transmit almost an infinite variety of sound vibrations, so the nerves of the retina were probably equally capable of conveying all kinds of light vibrations Prof Rutherford had further pointed out that the image of a star could not possibly cover three nerve-terminals at once, and therefore could not be seen as white if Young's theory was correct The author then described Helmholtz's experiments with a small hole in a screen illuminated by spectrum colours For red illumination the greatest distance at which the hole could be seen sharply defined was 8 feet, and for violet 1½ feet When the hole was covered with purple glass, or with red and violet glasses superposed, and a bright light placed behind, the eye, when accommodated for red light, saw a red spot with a violet halo round it, and when focussed for violet light, saw a violet spot with circle of red These experiments the author thinks show that the chromatic sense in distinct vision under critical conditions (i e where a single nerve or a small group of nerves is concerned) depends on the colours being brought to foci at different distances behind the crystalline lens He also infers that the same focal position in the eye cannot convey simultaneously the compound impression of widely separated colours Helmholtz's observations are further examined in the paper, and a series of zoetrope and colour disc experiments described which tend to show that the eye cannot follow rapid changes of colour. Changes from red to violet could be followed much more quickly than from violet to red. The red impressions were, however, more permanent The observed effects were found to depend on the intensity of the light, and also on the distance of the eye from the coloured surface. Summing up his observations, the author infers that by systems of accommodation of the eye, the colours of the spectrum are brought to focus on special parts or points of the rods or cones of the retina, such focal points being equivalent, by equal depths or distances from the crystalline lens, to a focal plane formed across the whole series of nerve terminals. That all the rays of light from an object, or part of an object, of very small area and of any spectrum colour, will converge to

a point upon a nerve terminal, and that this terminal will be most excited by the light At the end of the paper Dr Stanley Hall's views of nerve structure are examined Captain Abney thought the results of the zoetrope experiments were what one would have expected when pigmentary colours were used To be conclusive, such experiments must be conducted with pure spectrum colours The statement about the size of star images being less than that of a nerve terminal would probably need revision Speaking of colour vision, he said the modern view was to regard light as producing chemical action in the retina, which action gave rise to the sensation of colour On the author's theory he could not see how colour-blindness could be explained Mr Trotter said he understood Helmholtz to have proved that nerves could distinguish quantity, but not the quality of a stimulus Since the speed at which stimuli travelled to the brain was about 30 metres a second, the wave length of a light vibration, if transmitted in this way, would be very small Taking Lord Kelvin's estimate of the minimum size of molecules of matter, it followed that there must be many wave lengths in the length of a single molecule This, he thought, hardly seemed possible Mr Lovibond pointed out that the observations referred to by the author could be equally well explained on the supposition that six colour sensations existed The confusion of colours he had mentioned arose from lack of light Mr Stanley replied to some of the points raised by Captain Abney In proposing a vote of thanks to Mr Stanley, the chairman said it had been shown that light could be resolved into three sensations, but it was not known how this resolution occurred Prof S P Thompson said the gist of Mr Stanley's paper seemed to be that lights of different colours were concentrated at points situated at different depths in the retina, the violet falling on the part nearest the crystalline lens, and the red furthest away Another view of the action was that the different sensations might be due to the vibrations of longer wave length having to travel greater distances along the nerve terminals before they were completely absorbed

Mathematical Society, January 12 —Mr A. B Kempe, F R S , President, in the chair —The President (Prof Elliott, F R S , Vice-President, in the chair) read a paper on the application of Clifford's graphs to ordinary binary quantics (second part) In the first part it was pointed out that by some small modifications and a recognition of the fact that the covariants of $f(x, y)$ are invariants of the two quantics $f(X, Y)$ and $(Xy - Yx)$, the theory of graphs, which had been left in an unfinished state by the late Prof Clifford, furnished a complete method of graphically representing the invariants (and therefore the covariants) of binary quantics The method as modified depends essentially on the fact that any invariant, when multiplied by a suitable number of polar elements U, U′, V, V′, &c , can be expressed as a "pure compound form" (or sum of two or more such forms), the product of a number of "simple forms" Each of the latter has a "mark," viz one of the letters $a, b, c,$ and has also a certain valence, 0, 1, 2, 3, &c and these being given it is fully defined, *e g* , the simple form of mark a and valence 3 is graphically



having three radiating bonds, and is algebraically

$$a_0\,\mathrm{UVW} + a_1\,(\mathrm{U'VW} + \mathrm{UV'W} + \mathrm{UVW'}) + a_2\,(\mathrm{UV'W'} + \mathrm{U'VW'} + \mathrm{U'V'W}) + a_3\,\mathrm{U'V'W'},$$

the pairs of polar elements U, U′; V, V′; and W, W′, corresponding to the three bonds of the graphical representation A pure compound form is graphically represented by a number of simple forms having their bonds connected so that there are no free ends. If in the algebraical expression of a compound form two simple forms both contain the pair of polar elements U, U′, there will be a bond connecting their graphical representations; if the two simple forms both contain two pairs of such elements, viz. U, U′ and V, V′, there will be two bonds connecting their graphical representations and so on ; if they contain no common pair their graphical representations will have bond connecting them, A pair of polar elements will appear in two simple forms only, so that each bond in the graphical representation of a compound form corresponds to a distinct pair of polar elements If the algebraical expression corresponding to a graph be multiplied out, it will be found to consist of two distinct factors, viz :—(1) the product of all the polar elements, and (2) a function of the letters a_0, a_1, a_2 , $b_0, b_1, b_2,$, &c , &c. , corresponding to the marks a, b, &c of the simple forms contained in the compound form represented by the graph, the latter factor being an invariant of the quantics

$$(a_0, a_1, a_2, \ldots a_\alpha)(x, y)^\alpha$$
$$(b_0, b_1, b_2, \ldots b_\beta)(x, y)^\beta$$
$$\&c., \&c$$

where α is the valence of the simple forms of mark a, which are here supposed to be all of the same valence, and similarly in the case of β, γ, &c

In this second part a method of algebraically representing invariants is considered, which is directly derivable from the method of the first part, and was suggested by the graphs, but differs essentially from the earlier method in that it is independent of the use of polar elements. It shows, moreover, that the graphs may be regarded as absolutely equivalent to the invariants they represent, in lieu of being equivalent to those invariants multiplied by a number of polar elements. This second method deals in the first instance with "primary" invariants, *i e* invariants of two or more quantics linear in the coefficients of each If these quantics are

$$(a_0, a_1, a_2, \ldots a_\alpha)(x, y)^\alpha$$
$$(b_0, b_1, b_2, \ldots b_\beta)(x, y)^\beta$$
$$\&c , \&c ,$$

and we take

$$a = a_1 \frac{d}{da_0} + a_2 \frac{d}{da_1} + a_3 \frac{d}{da_2} + \&c \quad \textit{ad infinitum}$$
$$b = b_1 \frac{d}{db_0} + b_2 \frac{d}{db_1} + b_3 \frac{d}{db_2} + \&c \quad \textit{ad infinitum}$$
$$\&c , \&c.$$

we may express any primary invariant by an expression, or the sum of two or more expressions, consisting of the product of differences of the operators a, b, operating upon the product of the corresponding leading terms, a_0, b_0, &c Thus

$$(a - b)^2 a_0 b_0 \equiv a_2 b_0 - 2a_1 b_1 + a_0 b_2$$

is an invariant of the two quantics

$$a_0 x^2 + 2a_1 xy + a_2 y^2,$$
$$b_0 x^2 + 2b_1 xy + b_2 y^2,$$

linear in the coefficients of each , and

$$(a - b)^2 (a - c) a_0 b_0 c_0 \equiv a_3 b_0 c_0 - a_2 b_0 c_1 - 2a_2 b_1 c_0 + 2a_1 b_1 c_1 + a_1 b_2 c_0 - a_0 b_2 c_1$$

is a similar invariant of the three quantics

$$a_0 x^3 + 3a_1 x^2 y + 3a_2 xy^2 + a_3 y^3$$
$$b_0 x^2 + 2b_1 xy + b_2 y^2$$
$$c_0 x + c_1 y$$

These two invariants are graphically represented by

 and 

respectively, where the relation between the algebraical and graphical expressions is obvious, viz to every letter p in the algebraical representation there corresponds a nucleus including the mark p, and to every factor $(p - q)$ in the algebraical representation there corresponds a bond connecting the nuclei of marks p and q

We can pass to invariants of higher degrees in the coefficients of the various quantics by substituting like coefficients for unlike Thus, if we make $b_0 = a_0$, $b_1 = a_1$, $b_2 = a_2$, the primary invariant

$$a_2 b_0 - 2a_1 b_1 + a_0 b_2$$

becomes the invariant of degree 2

$$2(a_0 a_2 - a_1^2)$$

of the single quantic

$$a_0 x^2 + 2a_1 xy + a_2 y^2.$$

This invariant will be graphically represented by substituting the mark a for the mark b in the graph representing the corresponding primary invariant

If we proceed to deal in the same way with the invariant,

$$a_3 b_0 c_0 - a_2 b_0 c_1 - 2a_2 b_1 c_0 + 2a_1 b_1 c_1 + a_1 b_2 c_0 - a_0 b_2 c_1,$$

we get, as the invariant represented by substituting for the marks b and c the mark a, the expression of the third degree,

$$a_3 a_0^2 - 3a_2 a_1 a_0 + 2a_1^3.$$

This is not an invariant of a single quantic, but of the three

$$a_0x^3 + 3a_1x^2y + 3a_2xy^2 + a_3y^3$$
$$a_0x^2 + 2a_1xy + a_2y^2$$
$$a_0x + a_1y$$

It bears, however, a definite relation to the first of these three quantics, viz it is a *seminvariant* of that quantic, being in fact the source of its cubic-covariant J The paper points out that all seminvariants are thus invariants of two or more quantics, and can therefore be represented by graphs, the difference between a graph representing an invariant of a quantic and one representing a seminvariant of the same quantic consisting merely in this, that the simple forms, *i e* the small circles or nuclei of the graphs in the former case are all of the same "valence," *i e* have the same number of bonds, while in the latter, though of like marks, they differ in valence The classification of seminvariants, according to the valences of the simple forms composing them, or, in other words, according to the orders of the quantics of the systems of which they are respectively invariants, obviously throws considerable light upon their structure

The paper also deals with the breaking up of graphs into simpler ones, and gives a theorem upon the subject which leads to some interesting results It points out, moreover, how the graphs representing the sources of covariants can be instantaneously derived from those representing the covariants themselves

On the evaluation of a certain surface integral and its application to the expansion of the potential of ellipsoids in series, Dr Hobson

On the vibrations of an elastic circular ring, by Mr A E H Love —The ring is supposed to be of small circular section of radius c, and the elastic central-line a circle of radius a There are four ways of displacing the ring A point on the central-line may move along the radius of the circle which is its primitive form, or perpendicular to the plane of this circle, or along the tangent to this circle, and the circular sections may be displaced by rotation about the central-line The modes of vibration fall into four classes, of which two are physically important —Class I. Flexural vibrations in plane of ring —These were investigated by Hoppe in 1871 (*Crelle*, bd lxxiii) The motion of a point on the elastic central line is compounded of a displacement in and out along the radius and a displacement along the tangent to the circle, so proportioned that the central-line remains unstretched, and the nodes of the former displacement are the antinodes of the latter There must be at least two wave-lengths to the circumference, and the frequency ($p/2\pi$) of the mode in which there are n wave-lengths to the circumference is given by the equation

$$p^2 = \tfrac{1}{4}\,\frac{n^2(n^2-1)^2}{n^2+1}\,\frac{E}{\rho_0}\,\frac{c^2}{a^4}$$

in which E is the Young's modulus, and ρ_0 the density of the material Except for the numerical coefficient this is precisely similar to the formula for the lateral vibrations of a straight bar of the same material and section and of length πa (for which the fundamental tone has the same wave-lengths). The sequence of component tones when n is very great is ultimately identical with that of the tones of a free-free bar of length πa, but the sequence for the low tones is quite different to that for a bar Class II Flexural vibrations perpendicular to the plane of the ring.—It is found to be impossible to make the ring vibrate freely so that each particle of the elastic central-line moves perpendicular to the plane of the ring, unless at the same time the sections turn about the central-line through a certain angle The flexure perpendicular to the plane of the ring is always accompanied by *torsion* As in Class I. there must be at least two wave-lengths to the circumference, and the frequency of the mode in which there are n wave-lengths to the circumference is given by the equation

$$p^2 = \tfrac{1}{4}\,\frac{n^2(n^2-1)^2}{1+\sigma+n^2}\,\frac{E}{\rho_0}\,\frac{c^2}{a^4}$$

where σ is the *Poisson's ratio* for the material and the other constants have the same meaning as before. (For most hard solids σ is about $\frac{1}{4}$.) Since n must be at least 2 the sequence of tones is very nearly the same as in the vibrations of Class I, but the pitch is slightly lower, the ratio of the frequencies for the gravest tones being $\sqrt{\frac{21}{20}}$, which is very little less than a *comma*. For the higher tones, as we should expect, there is no sensible difference These two classes include all that have much physical importance The remaining types can be classified as —Class III Extensional vibrations —The motion may be purely radial or partly radial and partly tangential In the second case there will be an integral number of wave lengths, and when this number is n we have the formula for the frequency

$$p^2 = (1+n^2)\,\frac{E}{\rho_0}\,\frac{1}{a^2}$$

Putting n = zero we find the frequency of the purely radial vibrations The pitch of any mode of extensional vibration of the ring is of the same order of magnitude as the pitch of the corresponding longitudinal vibration of a bar of length equal to half the circumference, the formula for the latter being in fact derived by writing n^2 for $1+n^2$ Class IV Torsional vibrations —The motion consists of an angular displacement of the sections about the elastic central line accompanied by a relatively very small displacement of the points on this line perpendicular to the plane of the ring When there are n wave-lengths to the circumference the frequency is given by the formula

$$p^2 = (1+\sigma+n^2)\,\frac{\mu}{\rho_0}\,a^2,$$

in which μ is the *rigidity* of the material There is one symmetrical mode for which n is zero, and since $2\mu(1+\sigma) = E$, the frequency of this mode is $\frac{1}{2}\sqrt{2}$ of that of the radial vibrations The pitch of the torsional vibrations is comparable with that for a straight rod of length equal to half the circumference, the formula for the latter being in fact derived by writing n^2 in place of $1+\sigma+n^2$ Formulæ equivalent to those given in connection with Classes II and IV have been obtained by Mr Basset (Proc Dec 1891), but he has not interpreted his results

Entomological Society, February 8.—Mr Henry John Elwes, president, in the chair —The President announced that he had nominated Mr F DuCane Godman, F R S, Mr Frederic Merrifield, and Mr George H Verrall as Vice Presidents during the Session 1893–1894.—Mr S Stevens exhibited a specimen of *Chærocampa celerio*, in very fine condition, captured at light, in Hastings, on September 26 last, by Mr Johnson —Mr A J Chitty exhibited specimens of *Gibbium scotias* and *Pentarthrum huttoni*, taken by Mr Rye in a cellar in Shoe Lane He stated that the *Gibbium scotias* lived in a mixture of beer and sawdust in the cellar, and that when this was cleaned out the beetles disappeared The *Pentarthrum huttoni* lived in wood in the cellar.—Mr McLachlan exhibited a large Noctuid moth, which had been placed in his hands by Mr R. H Scott, F R S., of the Meteorological Office. It was stated to have been taken at sea in the South Atlantic, in about lat 28° S., long. 26° W Colonel Swinhoe and the President made some remarks on the species, and on the migration of many species of Lepidoptera.—Mr W F H Blandford exhibited larvæ and pupæ of *Rhynchophorus palmarum*, L, the Gru-gru Worm of the West Indian Islands, which is eaten as a delicacy by the Negroes and by the French Creoles of Martinique. He stated that the existence of post-thoracic stigmata in the larva of a species of Rhynchophorus had been mentioned by Candèze, but denied by Leconte and Horn. They were certainly present in the larva of *R palmarum*, but were very minute —Mr. G T Porritt exhibited two varieties of *Arctia lubricipeda* from York, an olive-banded specimen of *Bombyx quercus* from Huddersfield, and a small melanic specimen of *Melanippe hastata* from Wharncliffe Wood, Yorkshire —Mr H Goss exhibited species of Lepidoptera, Coleoptera, and Neuroptera, sent to him by Major G H Leathem, who had collected them, last June and July, whilst on a shooting expedition in Kashmir territory, Bengal. Some of the specimens were taken by Major Leathem at an elevation of from 10,000 to 11,000 feet, but the majority were stated to have been collected in the Krishnye Valley, which drains the glaciers on the western slopes of the Nun Kun range Mr Elwes remarked that some of the butterflies were of great interest —Mr. G. F Hampson exhibited a curious form of *Parnassius*, taken by Sir Henry Jenkyns, K.C B, on June 29 last, in the Gasternthal, Kandersteg —Mr. J. M Adye exhibited a long series of remarkable varieties of *Boarmia repandata*, taken last July in the New Forest.—Mr C O Waterhouse exhibited a photograph of the middle of the eye of a male *Tabanus*, showing square and other forms of facets, multiplied twenty-five times.—Mr. R. Trimen, F.R.S., communicated a paper entitled "On some new, or imperfectly known, species of South African

Butterflies," and the species described in this paper were exhibited —Mr T D A. Cockerell communicated a paper entitled "Two new species of *Pulvinaria* from Jamaica."—Mr Martin Jacoby communicated a paper entitled "Descriptions of some new genera and new species of Halticidæ"

Linnean Society, February 2 —Prof Stewart, President, in the chair —On behalf of Mr Thomas Scott, the Secretary read a report on the entomostraca from the Gulf of Guinea, collected by Mr John Rattray —Mr H. Bernard gave an account of two new species of *Rhax*.—An important paper by Mr Arthur Lister, on the division of nuclei in the mycetozoa, gave rise to an interesting discussion, in which Dr D H Scott, Prof Howes, and others took part —This was followed by a paper on the structural differentiation of the protozoan body as studied in microscopic sections, by Mr J E Moore The meeting adjourned to February 16

PARIS

Academy of Sciences, February 6 —M de Lacaze-Duthiers in the chair —On the variations in the intensity of terrestrial gravitation, by M d'Abbadie Observations begun in 1837 at Olinda (Brazil), on the variations in the direction of gravitational force also made its constancy doubtful Experiments on falling bodies revealed irregularities similar to those described (last number) by M Mascart The closed barometer employed by the latter may be termed a *brithometer* —On the preparation of carbon under high pressure, by M. Henri Moissan (see article) —On the reproduction of the diamond, by M C Friedel Remarks by M Berthelot (see article) —On the pathogeny of diabetes, part played by the expenditure and the production of glycose in the deviations of the glycemic function, by MM. A Chauveau and Kaufmann The same inferiority of venous with respect to arterial blood, as regards the amount of sugar contained in it, occurs in all the deviations of the glycemic function produced by a lesion of the central nervous system This inferiority is equally pronounced in the hyperglycemia resulting from the extirpation of the pancreas.—On the progress of the art of surveying with the aid of photography, in Europe and America, by M A Lausedat Since 1888 a zone of twenty miles on each side of the Canadian Pacific Railway, in the neighbourhood of the Canadian National Park, has been surveyed with the aid of photography under the direction of Messrs Deville, Drewry, and McArthur, at an average rate of 1040 square km per annum for four men under great climatic disadvantages. The cost of the undertaking amounts to three dollars per square km —Determination of the amount of carbonic oxide which can be contained in confined air, by means of a bird employed as physiological reagent, by M N Gréhant —On the properties of faculæ, reply to a note by Mr. G Hale, by M H Deslandres —The probability of coincidence between solar and terrestrial phenomena, by M G. E Hale —Note on an explicit expression of the algebraic integral of a hyperelliptic system of the most general form, by M F de Salvert —On a generalisation of Bertrand's curves, by M. Alphonse Dumoulin —On the surfaces which admit a system of lines of spherical curvature and which have the same spherical representation for their lines of curvature, by M Blutel —On semicircular interference fringes, by M G Meslin Rectilinear interference fringes are sections of hyperboloids by planes parallel to their axis, the light being propagated in a direction at right angles to that axis. If the light proceeds along the axis, a screen perpendicular to it will cut circular sections, and the fringes will have the form of a circumference of which a greater or smaller arc will be seen accordingly as the two pencils overlap more or less In practice these circular fringes were obtained by separating two of Billet's half lenses and placing them one before the other in front of a very small hole illuminated by sunlight, such that the axis of the pencil passes through the optical centre of the two lenses. Under these conditions two pencils are formed from the same source of light, which may be made to show circular fringes by moving the lenses slightly in a direction perpendicular to their optical axes.—Study of the fluorides of chromium, by M. C. Poulenc.—On a new soldering process for aluminium and various other metals, by M. J. Novel. For aluminium the following solders are recommended: (1) Pure tin, fuses at 250°. (2) Pure tin 1000 gr, lead 50 gr. (280° to 300°) (3) Pure tin 1000 gr.; pure zinc 50 gr (280° to 320°). These solders do not stain or attack aluminium. A nickel soldering bit is preferable. (4) Pure tin 1000 gr.; red copper 10 to 15 gr (350° to 450°) (5) Pure tin 1000 gr, pure nickel 10 to 15 gr (350° to 450°) These give a slightly yellowish tint, but are very durable (6) Pure tin 900 gr., copper 100 gr, bismuth 2 to 3 gr This is specially suitable for soldering aluminium bronze —Action of acetic acid and formic acid upon terebenthine, by MM. Bouchardat and Oliviers —On the mode of elimination of carbonic oxide, by M L de Saint Martin Experiment shows that animals partly intoxicated by carbonic oxide, when placed in conditions under which natural elimination is impossible, destroy slowly but regularly a certain quantity of the poisonous gas, this destruction being the more active the less the intoxication. It is probably converted into carbon dioxide The toxic effect is entirely dependent upon the time during which the organism is exposed to the gas, and a very small quantity can be fatal on prolonged exposure —Influence of pilocarpine and floridzine on the production of sugar in milk, by M Cornevin —On the seat of the colouring matter in the green oyster, by M Joannes Chatin —On pseudo-fertilisation in the *Uredines*, by MM P A Dangeard and Sapin-Trouffly —On the substances formed by the nucleole in *Spirogyra setiformis*, and the directive force which it exerts upon them at the moment of the division of the cellular nucleus, by M Ch Decagny —On a process for measuring the double refraction of crystalline plates, by M Georges Friedel.—A horizontal section of the French Alps, by M W Kilian —On the arrangement of the cretaceous beds in the interior of the Aquitaine basin, and their relations to tertiary formations, by M Emmanuel Fallot.

MAN AND EVOLUTION

Evolution and Man's Place in Nature By Henry Calderwood, LL D, F R S E, Professor of Moral Philosophy, University of Edinburgh (London Macmillan and Co, 1893)

THIS work appears to have been written for the purpose of setting forth the author's views as to the twofold nature and origin of man He admits, fully and unreservedly, that both the bodily organism and the lower mental nature of man have alike been developed by a process of evolution from a lower animal form, but he urges with much force, and often with both eloquence and dialectic skill, that the rational and moral nature of man has not been thus developed

The book, however, has many defects, and one cannot but feel that the writer has undertaken a task somewhat beyond his powers Most prominent is its extreme diffuseness and vagueness, the want of systematic treatment, the frequent reiteration of the same ideas under different forms of words, and the misconceptions arising from want of familiarity with many of the subjects discussed We are also annoyed by the frequent reference to problems to be discussed or solved, which are yet only hinted at or talked about later on Thus, in the first chapter, we are told that a "fuller study of human life" is now required, and that the crowning effort of science in the study of Nature must be "the solution of the problem of man's appearance" on earth Yet no attempt is made in the whole volume, either to solve this problem or even to show what progress has been made towards solving it At p 154 we are told that—"We are now ready for consideration of Darwin's argument"—as to the relation of the mental nature of man and the lower animals And on the next page—"The direction to be followed now becomes more obvious"—after which we have pages of general remarks on the intelligence of the dog and the ant Then, at p 162—"The method to be followed is clear we must compare the higher animals with man"—and —"careful comparison of the two orders of life is the only course open for scientific inquiry," and again,—"The difficulties belonging to such a mode of inquiry are many, but no easier method is available" Then, at p 167, we find that Darwin "has at least suggested the essential conditions of our inquiry" After this we have another series of vague general remarks, till at p 171 we find another statement of the mode of inquiry, and we are told that "we must have in full view all that is common to man, as animal, with the higher mammals, making account of close approximation in organic structure" Yet we nowhere find any attempt to apply these principles or methods so laboriously set forth, but are put off with such statements as—"In proof of exercise of intelligence, examples are many and familiar, making it unnecessary to enter upon detailed references" Then we are interrupted by fifteen pages of remarks on instinct among insects, although it has been repeatedly stated that the relation of man to the higher animals was the problem to be discussed; and at p. 193, we are told that—"Now at length, after careful survey of lower levels, we advance towards the height, on which the grand problems of intelligence become visible Study of comparative intelligence now becomes possible" Then follow again page after page of what can only be described as "general remarks" on horses, dogs, monkeys, and other animals We are told, for example—"When the higher animals are compared with the lower, it is clear that a power of intelligence must be attributed to the higher, which cannot be credited to the lower Phenomena of domestication come to our aid here, confirming this generalisation" And a little further on, as a proof that dogs can interpret signs and act upon them, we have the following concrete illustration, among the very few in the book, and therefore we may presume it is considered a valuable one "'Go home' will send one dog back, but the Gaelic equivalent alone will be effective in the case of a dog reared in the Highlands of Scotland, where the Celtic tongue is in common use" And then, as if the intelligent reader might doubt this astounding fact, the author adds, "Observation affords ample testimony for this"

Although the author has evidently read very widely on the subject of evolution, his want of grasp of the subject is continually shown Thus, when discussing the struggle for existence, he seems to think that this is usually considered to be limited to a struggle for food He says —"A general view of the relations of life and environment will guard against interpretation of facts exclusively by reference to struggle for existence consequent on the relations of numbers to food-supply" "Life is too rich in variety to find adequate explanation of its history in the mere balancing of our numbers with food-supplies" "In no life is progress to be explained exclusively by reference to amount of food-supply". "environment must be read much more largely than could be suggested by mere dependence on materials for nutriment" —the above passages all occurring in a single paragraph.

We have to thank the author, however, for the very clear manner in which he admits, and even enforces the application of evolution to man He states this conclusion in several places. Thus, at page 261, we find the following —

"The novelty of the situation lies in this, that man's alliance with all animal life has been established with a clearness and fulness of representation never before possible in the history of the world The long-hidden secrets of nature are disclosed, and, behold! man has his heritage among the beasts of the field The discovery is indeed a large one, the demonstration has been worked out in minute detail till no place is left for doubt"

By far the best portion of the work is that which is its special feature—the discussion of the rational as contrasted with the mere perceptive and intelligent nature of man and of the lower animals A few quotations will explain the author's views, and show him at his best

"The conditions of action are changed when rational self-direction comes into view This change is so great as to amount to a complete contrast with all that has appeared in lower forms of life Passion and appetite have not disappeared: they are present as before, but instead of determining conduct, a new exercise of power has appeared to control them. Life has here a duality within it, which has not been seen at any lower stage.

T

Life's history becomes in this way a history of conflict, of which no trace has appeared at any earlier point in natural history The struggle between individuals has not disappeared, but a struggle within the individual life occurs, which has never been visible in the history of any inferior order of life" (p 55)

Another aspect of the rational nature is thus defined :—

"The difference which severs man from the animals lies beyond the craving, and the cunning, and the consuming of what has been captured We trace it in his plans for the day, in his preparation of his weapons, in his survey of the heavens, in his taking of reckonings for direction He deals with the relations of means to ends, he utilises past experience in his reflections over what has happened , he reaches general conclusions" (p 270)

Perhaps the finest passage in the book is at p. 287, tracing the moral element in the thought of all kinds of men and all diversities of race, as shown by the sense of wrong and injustice We can only give here the concluding lines —

"To this appeals the criminal in the heart of our surging crowds, placed under arrest, if he should be condemned on insufficient evidence To this appeals every buyer in the market, defrauded by the thrusting of adulterated goods into his hands And to this does every gentle one make appeal, defrauded in ways still worse, by false expressions of love, from whose falseness recoils a blighted life, bearing through long and weary years witness to the cruel wrong that has been done Where, along the devious paths in which man is found, is justice not honoured, at least by outcry against harsh wrongs?"

There is much in this volume that will attract readers more disposed towards the esthetical and moral than towards the scientific aspects of evolution Agreeing, as the present writer does, with most of the conclusions of the author, he can but regret that they have not been set forth in a manner more likely to attract scientific readers A. R W

POINCARÉ'S "THÉORIE MATHÉMATIQUE DE LA LUMIÈRE."

Théorie Mathématique de la Lumière Par H Poincaré, Membre de l'Institut (Paris: G Carré, 1889 and 1892)

THIS work consists of two volumes, the first of which comprises a course of lectures delivered by the author in 1887–1888, whilst the second contains a further course delivered in 1891–1892

The first volume commences with a discussion of the constitution of the luminiferous ether, in which the latter is regarded as a system of discret molecules in stable equilibrium under the action of molecular forces, and the author finally deduces equations of motion of the same form as those which are furnished by the ordinary theory of isotropic elastic media. He then adopts the hypothesis, originally due to Lord Kelvin, that the velocity of propagation of the longitudinal wave is practically zero The principle of Huygens is next dealt with, and this is followed by a chapter on diffraction. A complete discussion of all the difficulties attending the resolution of waves would carry us too far, but the author does not appear to be acquainted with the masterly investigation of Sir G Stokes, or the formula deduced by him, which gives the effect of an element of a plane wave at a distant point, and which enables the unsatisfactory reasoning on which the principle of Huygens depends to be dispensed with The diffraction of light diverging from a focus is next discussed, and the intensity of light diffracted by a circular aperture or disc is obtained in the particular case in which the point of observation is the projection of the centre of the aperture or disc upon a screen, but no mention is made of Prof. Lommel's able investigation in the general case of an excentric point A few stock problems relating to the diffraction of parallel rays are also discussed, but nothing is said about the resolving power of optical instruments, or the theory of gratings, including Prof Rowland's ingenious invention of concave gratings

Chapter V commences with the theories which have been proposed to explain the photogyric properties of quartz and certain organic substances, and concludes with an account of some of the theories of *ordinary* dispersion This is followed by a long chapter which begins with Fresnel's theory of double refraction, and then proceeds to discuss the theories of Cauchy, Neumann, Sarrau and Bousinesq

In all these theories the ether is regarded as an æolotropic elastic medium, and in considering them the author is to be congratulated on having shown no sympathy with the small minority who regard the writing down of equations as a foolish process, but although during recent years much time has been spent in elaborating such theories, it may be questioned whether the majority of them have contributed any very substantial addition to scientific knowledge The theory of the propagation of waves in an æolotropic elastic medium was rigorously investigated by Green as long ago as 1839, and although a theory of this kind is useful in enabling the mind to form a mental representation of the mechanism which is required to produce double refraction, it is well known that Green's theory, and all others of a similar character, fail to furnish a satisfactory explanation of this phenomenon. The principal defects of such theories are, that although most of them lead to Fresnel's wave surface, or to one which is a very close approximation thereto, they require us to suppose that the vibrations of polarized light are parallel instead of perpendicular to the plane of polarization, and they also fail to give results which explain crystalline reflection and refraction, unless certain additional assumptions of a very questionable character are made Probably it will not be thought an exaggeration to say, that the only theory of elastic media which satisfactorily explains double refraction is the one which is due to the joint labours of Lord Rayleigh, Lord Kelvin, and Mr Glazebrook.

At the commencement of Chapter VII, which deals with reflection, the following statement is made (see p 320).—

"La réflexion vitreuse a donné lieu à trois théories également confirmé par l'expérience, ce sont celle de Fresnel, celle de Neumann et MacCullagh et celle de Cauchy"

The theories of Neumann and MacCullagh depend upon the hypothesis that the *density* of the ether is the same in all media, and that it is the rigidity which

varies, and it is somewhat surprising that M Poincaré does not appear to be aware of the investigations of Lorenz and Lord Rayleigh, who completely exploded this hypothesis twenty years ago by showing that it leads to two polarizing angles. The weak point in the investigations of most French mathematicians on the subject of reflection and refraction arises from the fact that, in consequence of their not having made a careful study of Green's papers and the subsequent developments by Lord Rayleigh and Lord Kelvin, they are unable to deal satisfactorily with the longitudinal or pressural wave. The difficulties arising from the existence of these waves may be got rid of either by assuming, as Green did, that the ratio of the velocity of propagation of the longitudinal wave to that of the transverse wave is very large, or, by adopting Lord Kelvin's hypothesis, that the above ratio is very small, but it cannot be too emphatically stated that the existence of such waves must not be disregarded, and that any attempt to ignore them will inevitably end in failure.

This chapter concludes with a brief account of metallic reflection, in which the author has adopted the equations of motion given by Voigt. The chief difficulty in trying to explain metallic reflection, by the introduction of a viscous term into the equations of motion, is due to the fact that Eisenlohr has shown that for certain metals the pseudo refractive index is a complex quantity whose real part is negative.

Turning now to Volume II, which consists of a further course of lectures delivered in 1891–1892, we find that it commences with the theory of isotropic elastic media in its ordinary form. Next follows a chapter on the electromagnetic theory, in which the author confines himself to the case of an isotropic medium, and has given no account of the investigations of Glazebrook on crystalline reflection and refraction, in which it is shown that the intensities of the reflected and refracted waves satisfy the same equations as those deduced many years previously by MacCullagh from an erroneous theory, but which nevertheless explain the facts in a fairly satisfactory manner. M Poincaré assumes that the vector potential satisfies the solenoidal condition; but although the employment of the vector potential is valuable as a mathematical artifice, its use requires extreme care, inasmuch as it contains an undetermined quantity, and I believe it can be proved that in certain cases the solenoidal condition is not satisfied. In the electromagnetic theory of light this difficulty can always be evaded by eliminating the vector potential from the equations, which is the preferable course to pursue.

In Chapter V, after discussing ordinary reflection and refraction, the author attempts to construct an electromagnetic theory of metallic reflection and refraction by taking into account the conductivity. This theory leads to Cauchy's formulæ, but requires that the real part of the pseudo-refractive index should be positive, whereas Eisenlohr has shown that for certain metals these formulæ cannot be reconciled with experiment unless the real part is negative. In the case of steel this quantity is positive throughout the whole range of the visible spectrum; but as thin films of iron when magnetized, exhibit anomalous dispersion, it is doubtful whether this hypothesis is satisfactory even in the case of steel or iron.

The next four chapters are devoted to the principle of Huygens and to diffraction, and in Chapter X. the author has discussed Von Helmholtz's theory of anomalous dispersion. The advantage of theories of the class to which that of Von Helmholtz belongs is, that they endeavour to account for dispersion and absorption by taking into account the mutual reaction between ether and matter, and show that when one or more of the free periods of the vibrations of the matter coincides with one or more of the free periods of the rays of the spectrum, absorption and anomalous dispersion will be produced. By the aid of this theory the absorption produced by sodium vapour may be accounted for, as well as the anomalous dispersion and selective reflection produced by fuchsine and other aniline dyes. The author has not, however, developed the consequences of this theory as far as might be done.

It is not unnatural that M Poincaré should have given special prominence to the writings of his own countrymen, his treatise would, however, have been much improved had he not confined himself so exclusively to the writings of French mathematicians, but had given a fuller account of the work done by mathematicians of other nationalities. A. B. BASSET

THE MOTHS OF INDIA.

The Fauna of British India, including Ceylon and Burma. Published under the authority of the Secretary of State for India in Council. Edited by W. F. Blanford. "Moths." Vol. I. By G. F. Hampson. (London: Taylor and Francis, 1892.)

MR HAMPSON is already favourably known to entomologists by his work on the "Lepidoptera Heterocera of the Nilgiri District," which forms Part viii of the series of "Illustrations of typical specimens of Lepidoptera Heterocera in the collection of the British Museum." In the work before us he has undertaken a far more important task, nothing less than a descriptive handbook of the moths of India, which, when complete, will prove as useful to Indian entomologists as the well-known work on the butterflies of India by Marshall and De Nicéville.

Hitherto the available information on the moths of India has been scattered over a great variety of books and periodicals, far too numerous and costly to be easily available out of London or Calcutta, and extremely difficult to use satisfactorily, even if accessible. But Mr Hampson has been given the fullest facilities for examining all the principal public and private collections of Indian moths, from that of the British Museum downwards, and has also made free use of the libraries of the British Museum at South Kensington, which now contain the finest series of entomological books in the world, and the result is a work which can hardly fail to give an enormous impetus to the collection and study of Indian moths.

Much attention has been paid to the classification of moths, and the introductory pages are occupied with details of structure, illustrated by woodcuts of parts of the head, antennæ, legs, and neuration. This is followed by a genetic tree of the families of moths, and by a

tabular key based chiefly on neuration and antennæ Mr Hampson admits thirty-four families of Indian moths, of which the first twenty three, including 1158 species, are dealt with in the volume before us The earlier families of moths are, however, much less numerous in species than the later ones, and it must not be supposed that Mr Hampson has dealt with anything like half the Indian species in his first volume, which comprises the series of families usually classed under Sphinges and Bombyces, extending, according to the author's classification, from *Saturniidæ* to *Hypsidæ* The important Bombycide families, *Arctiidæ*, *Agaristidæ*, and *Uraniidæ*, are, however, relegated to the second volume, while several families of more or less doubtful position find a place in vol i, such as the *Cymatophoridæ*, *Thyrididæ*, *Sesiidæ*, and *Tinægeriidæ* We observe that Mr Hampson closes the series of moths with the *Tineidæ*, *Pterophoridæ*, and *Alucitidæ*, and in this adopts the usual classification, though in the main he has struck out an entirely new classification of his own, and the very first innovation which meets the eye is the novelty of commencing the moths with the *Saturniidæ*

We hope that Mr Hampson will take an opportunity of discussing the various systems of classification of moths which have been proposed by Guenée, Herrich-Schaffer, Plötz, and other entomologists, not forgetting the strange system proposed by Zebrawski, in his work on the Lepidoptera of Cracow, in which the butterflies are placed in the middle instead of the beginning of the series of Lepidoptera. Such a discussion would be un suitable in the present work, but if published elsewhere might be very useful

Long descriptions of genera and species in a work of this character would have been out of place, and we are glad to find that they have been avoided Each family or subfamily is succinctly characterised, and usually illustrated by a figure of the larva. This is followed by a tabular key to the genera, and then by a notice of the genera and species The notice of each genus consists of synonymy, type, range, and a brief indication of the principal characters. That of the species includes synonymy, description, including both sexes, and transformations when necessary, range and expanse An excellent woodcut is usually given of one representative of each genus, showing the wings and body on one side, and the neuration on the other, extra figures of antennæ and legs being sometimes added

No book, however useful or carefully compiled, can be free from errors, but these cannot be detected at a glance, and the only technical mistake of importance which we have noticed in turning over Mr Hampson's work is that the broad-bordered Australian *Macroglossum kingii*, Macl, is included among the synonyms of the narrow-bordered *Cephonodes hylas*, Linn

Much, no doubt, remains to be said about Mr. Hampson's classification, his use of generic names, and his placing together insects regarded as distinct by other authors as synonyms. But these are all points admitting of great difference of opinion, and we do not propose to discuss them further in the present notice.

We should add that various new families, besides many new genera and species, are described by Mr. Hampson for the first time. W. F. K.

OUR BOOK SHELF

The Year-Book of Science (for 1892) Edited by Prof T G Bonney, D Sc, LL.D, F R S (London Cassell and Co, 1893)

ALL interested in scientific progress will welcome the appearance of the second volume of this useful year-book The staff of contributors includes such names as Dr Ramsay, Prof. Seeley, Mr Botting Hemsley, &c, and the accuracy of the summaries of the year's developments may therefore be thoroughly relied upon The plan of the volume follows closely on the lines of its predecessor, but it has been extended so as to include geographical and anthropological matters, and zoology has received more complete treatment If one may judge of the activity in different departments of science by the space required for the account of their progress, electricity and organic chemistry would appear to take the lead As in the last volume, no attempt has been made to present a complete catalogue of papers The object has been simply to select the memoirs of exceptional interest; and so far as we have been able to judge, the selections have been judicious An excellent index of subjects, and one of authors, complete what will no doubt be found a very useful volume

Treatise on Thermodynamics By Peter Alexander, M.A Pp xii, 203 (Longmans, Green, and Co, 1892)

THIS is in many respects a singular work Whole pages, we may almost say whole sheets, are devoted to the multiplication of elaborate proofs of intrinsically simple theorems for which a few lines would be ample allowance, while some of the real difficulties of the subject are but lightly touched on The other special characteristics, so far as we have seen, are three in number First, and most prominent, the extraordinary proportion of formulæ to text, which gives the whole the look of a treatise on Partial Differential Coefficients rather than on a branch of Physics Second, the fearful and wonderful collection of names for special cycles, *e g* *Isothermentropicycle*, *Isobarymegacycle*, *Isenergentropicycle*, &c Finally, the expressions of doubt or hesitancy with which many steps, universally recognised as valid, are introduced. In the first and second of these characteristics the author far transcends the results of the licence willingly allowed to pioneers like Clausius and Rankine But these have been (at least in great part) long since discarded, and can never be reintroduced. The third characteristic is, to say the least, not precisely one to be desiderated in a text-book, where we naturally expect to find some slight trace of "Sir Oracle"

Mediæval Lore an Epitome of the Science, Geography, Animal and Plant Folk-Lore and Myth of the Middle Ages Being Classified Gleanings from the Encyclopædia of Bartholomew Anglicus on the Properties of Things Edited by Robert Steele (London Elliot Stock, 1893)

THE original work of which parts are translated in the present volume, may be said to have a place of its own in the history of European literature It was written in the thirteenth century, and the Latin text was soon widely appreciated, while in the course of the fourteenth century it was translated into French, Spanish, Dutch, and English The book is full of interest, for it presents a summary of all that was known in the Middle Ages about man and the world The change which has been gradually effected by the use of modern scientific methods is, of course, incalculable; but some readers will probably be surprised to find to how large an extent Bartholomew mingles the results of shrewd and accurate observation with quaint fancies and unverified judgments The present volume consists of selections from the edition of Berthelet, 1535; and the good style of the translator adds greatly to the charm of the author's

philosophy and science Mr. Steele has done his work with much tact and care, and an interesting preface is contributed by Mr. William Morris

Astronomy for Every day Readers By B J Hopkins, F.R.A S. (London George Philip and Son, 1893)

THIS is a little book which aims at explaining in "as accurate and interesting a manner as possible such of the phenomena of the heavens as should be known to every intelligent person" It consists of six chapters dealing respectively with day and night, the phases of the moon, the tides, the seasons, eclipses, meteors, shooting stars, and comets Descriptive astronomy is not touched upon, but there is an introductory chapter giving a general survey of the solar system and its dimensions The book has been very carefully written, and the scientific explanations are much relieved by interesting references to the history of the subject The author has succeeded in giving very clear and concise accounts of the every-day phenomena with which the book specially deals, and it seems well adapted to awaken a desire for more in the class of readers to whom he more particularly appeals A biography of the author—who is described as "the working-man scientist"—is also included

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Blind Animals in Caves

IN an article in the current number of the *Contemporary Review* Mr Herbert Spencer discusses the "familiar instance" of blind animals in caves as bearing upon the hypothesis of the transmission of acquired characters Mr Spencer is not satisfied with the explanation of the blindness of these cave animals offered by Weismann, who endeavours to account for them by two conditions recognised as operating in regard to other cases by Darwin, viz cessation of selection and parsimony of growth ("Origin of Species," sixth edition, p 118), of which the former author has treated under the name Panmyxia. Mr. Spencer shows that the saving of ponderable material in the suppression of an eye is but a small economy he loses sight of the fact, however, that possibly, or even probably, the saving to the organism in the reduction of an eye to a rudimentary state is not to be measured by mere bulk, but by the non-expenditure of special materials and special activities which are concerned in the production of an organ so peculiar and elaborate as is the vertebrate eye

That, however, to which I wish here to draw the attention of Mr Spencer and his readers is this —Mr Spencer appears to think that if he disposes of Weismann's explanation of the blindness of cave-animals according to "Panmyxia"—there remains only the explanation by "transmission of acquired characters" in the field He appears not to be acquainted with the explanation which I have offered of the blindness of cave-animals It is closely similar to that given by Darwin of the occurrence of wingless insects on oceanic islands. My explanation consists in an application to the case in hand of Darwin's principle of "natural selection." I published it some years ago in my article "Zoology" in the "Encycl Britannica," reprinted in 1890 in a volume of essays, bearing the title "The Advancement of Science." My suggestion was (and is) as follows, and I should like to see what Mr. Spencer has to say to it:—"This instance (that of the blind cave animals) can," I wrote in the article above-named, "be fully explained by natural selection acting on congenital fortuitous variations. Many animals are thus born with distorted or defective eyes whose parents have not had their eyes submitted to any peculiar conditions. Supposing a number of some species of Arthropod or Fish to be swept into a cavern or to be carried from less to greater depths in the sea, those individuals with perfect eyes would follow the glimmer of light and eventually escape to the outer air or the shallower depths, leaving behind those with imperfect eyes to breed in the dark place A natural selection would thus be effected In every succeeding generation (bred in the dark place) this would be the case, and even those with weak but still seeing eyes would in the course of time escape, until only a pure race of eyeless or blind animals would be left in the cavern or deep sea."

My own position in regard to the hypothesis of the transmission of acquired characters remains what it was ten years ago, viz that in the absence of observed instances of this transmission and in the presence of repeated observation that particular acquired characters are *not* transmitted, I do not consider it legitimate to *assume* a transmission of acquired characters as the explanation of any given case, such, for instance, as that of the blind cave animals I am confirmed in this attitude by the fact that a little consideration has enabled me and others to explain satisfactorily, by reference to no hypothetical causes, but to the admitted and demonstrable facts of "congenital variation" and "natural selection," instances brought forward as "only to be explained on the assumption of the truth of Lamarck's hypothesis"

On the other hand, I have always considered that there is not sufficient ground for asserting that a transmission of acquired characters *can not* take place The important question is still as it was five years ago, "*Does* it take place?"

Oxford, February 14. E RAY LANKESTER.

Glacier Action.

I HAVE read with great interest and pleasure the short review in your paper of last week by Prof Bonney, giving a summary of the results of a survey of the French freshwater lakes, and indicating as the most probable conclusion that they cannot be accounted for on the theory of the late Sir A Ramsay, by the digging out power of glaciers

Living as I do in a highly glaciated country, and in a country also full of lakes, both fresh and salt, I have never believed in that theory Lakes seem to me to be due to the same causes which have produced the glens and hollows in which they lie, and these causes cannot be identified with glacier action alone The theory of Ramsay attributes to glacier action powers and effects which have never been proved to belong to them Glaciers do not dig out They rub down—abrade—and scoop, when they are moving down inclined planes at angles more or less steep. But when they reach level ground they do not dig, they rest upon the level surfaces, and when pressed from behind they flow over it But I have never seen any proof that they can act like a ploughshare, or rather like one of the new digging machines

In so far as all existing glens may have been formerly occupied by glaciers, their depths must have been increased by glacier action, on the supposition that they were tilted, or upraised at some angle required for this form of true glacier action On this supposition, indeed, lake basins may be said to be partly due to glaciers But then this supposition involves and depends upon the assumption that earth movements have made the lake basins what they now are—hollows in a comparative level

Like all other general theories in the history of geology, the "glacial theory" seems to me to have been ridden to the death, and I have been long waiting for some signs of that reaction or correction which is still much needed. I hold that in this country there is not only no evidence of "ice sheets" overriding all the hills, but the strongest evidence against such sheets Our glens had true glaciers in abundance, no doubt, and they have left their tool-marks very distinctly But those marks are quite inconsistent with one universal ice-cap or ice sheet over all the land ARGYLL.

Dr. Joule's Thermometers

EVERY one will, I am sure, be glad to know that Dr Joule's thermometers are under investigation by Prof. Schuster

It is unfortunate that Joule does not give the actual readings of the freezing point, but if the comparison quoted by Rowland was made in either 1879 or 1890 it may be that he referred to the reading of November, 1879, when the total rise of the zero point was 12·92 scale divisions In that case the original reading in April, 1844, would be 9 70, at any rate this number cannot be very far from the truth

The temporary changes of zero point alluded to by Prof Schuster certainly complicate the matter, but from the numbers given it would appear that since 1879 or 1880 there has been a

further secular rise of from 0 38 to 0 89 of a scale division Nothing is said in Joule's paper about the temperatures at which the thermometers had been kept before the readings of the freezing point were taken, but as the later observations—and most of the earlier ones—were made in the winter months, it may perhaps be assumed that the temperatures were nearer 7° than 30°, and that the actual reading on the scale last winter should be taken as nearer 23 51 than 23 00 If this is so the total rise of the zero point last winter would be nearer 13 81 than 13 30

Prof. Schuster states that "with properly annealed thermometers the secular changes are much smaller than the temporary ones," and that is no doubt true for observations extending over a limited time and with such comparatively large variations of temperature as from 7° to 30° It may be pointed out, however, that the secular rise since 1879 or 1880 is probably greater than the maximum temporary change recorded by Prof Schuster, and of course the total secular rise is enormously greater

It may be true that the secular changes of a thermometer gradually vanish, but it must, I think, be conceded, that in the case of Dr Joule's thermometer it will be a long time before absolute constancy is attained There can be no doubt that even now, nearly forty nine years after the first reading was taken, the zero point is still rising, and it does not appear to me to be very improbable that during the next fifty years there may be a further rise of two scale divisions, the amount calculated from the purely empirical formula which I have suggested

Foraminifer or Sponge?

UNDER the above heading in last week's NATURE Dr Hanitsch briefly draws our attention to Mr A Goes' report on the deep sea organisms procured by Prof Agassiz in the American tropical Pacific, which he describes as Arenaceous Foraminifera, with the name *Neusina Agassizi*

As it was from me that Dr Hanitsch received the specimens he describes, which I had after a personal conversation on the matter sent him, for his opinion as to their relation to true sponges, I venture to send some further observations on these interesting forms

Dr Hanitsch is, I believe, quite right in referring Mr Goes' Neusina to Prof. Haeckel's *Stannophyllum zonarium*, as described in his report on the *Challenger* deep sea Keratosa But while admitting my admiration of Prof Haeckel's wonderful production on the *Challenger* specimens, I do not agree with him as to their being true Keratose sponges

My conclusion is based upon the examination of nearly the whole *Challenger* collection, and in not one species could I find the slightest trace of any of the flagellated chambers characteristic of sponges.

Prof Haeckel accounts for the absence of this important feature through the bad preservation of the specimens Yet he describes the most delicate parts of a commensal Hydroid in full, and was able to observe amœboidal cells, and the granulated sarcode bodies peculiar to all bottom living Foraminifera.

If, however, the forms described by Prof Haeckel prove after all to be true Keratose sponges, the present state of our knowledge does not justify their separation from such recognised genera of Foraminifera, as Masonella, and Syringammina of the late Dr. G Brady, Technitella, Haliphysema, and Marsipella of Canon Norman, or *Hyperammina palmiformis*, described by myself from the Faröe Channel, all which forms have the power of forming siliceous and chitinous skeletons.

Without going into further detail here it will be readily understood that I quite agree with Mr Goes in placing these organisms among the Foraminifera, although it would have been better had he given us a clearer and more detailed description of his Neusina.

I had hoped to have published my personal observations on these most interesting organisms, but circumstances have prevented me doing so up to the present.

I for one would be glad if Dr. Hanitsch would give his opinion as to their supposed sponge structure, which he has not done in his previous letter F. G PEARCEY,

Late of the *Challenger* Expedition and Commission

Owens College Museum, Manchester.

Colonial Meteorology

ON p 363 of your last number your reviewer of the "Year-book of the Imperial Institute," after remarking that "climate certainly deserves better treatment," continues —

"We do not think space would be wasted in giving the mean monthly temperatures and rainfall for the average year and for two extreme years, at a few representative stations in the larger colonies This information cannot indeed be found in any existing books, but must be worked out from original records, which exist abundantly, and are rarely made available to practical workers "

I am afraid that the reviewer does not always read NATURE, for you, sir, have on several occasions noticed my efforts in this direction, efforts which have gone on uninterruptedly for twenty years. As, now that you have taken the matter up, it is not improbable that some of the funds lavished on the Imperial Institute may be devoted to the subject, and my small organisation be swamped or superseded, I hope that you will, in justice to the directors of the various Colonial observatories who have helped me for so many years, and as some consolation for the entire ignorement of our organisation by your reviewer, allow me to give its history in the fewest words possible

In 1873 I determined to try to publish monthly a table giving the principal climatic data for each synchronous month at widely spread stations over the entire British Empire The leading idea was identity, so as to ensure comparability I therefore prepared some blank forms and sent them with a circular letter to about twenty of our leading Colonial meteorologists Every one without exception promised to help, and it says much for colonial climate to add that during the subsequent twenty years not more than five or six of my original correspondents have passed away

During the period occupied in the transit of my request and of the replies thereto, I wrote a series of short articles pointing out the leading features, and as far as practicable the mean values, for the various stations, so that when we began publishing the monthly values, the departures from the mean could be recognised. These articles and the tables themselves from 1874 to 1881 appeared in *The Colonies* (subsequently *The Colonies and India*) When in 1882 that paper passed into other hands, the proprietors declined to publish the tables, and I began to insert them in the *Meteorological Magazine*, where they have appeared regularly month by month for the subsequent thirteen years At the close of each year an extra table is given with a summary of the results for the year, and NATURE has often done me the honour of quoting portions of these summaries

I enclose copy of our last table, and though I know that to reproduce it would be to make a somewhat large demand upon your space, I feel that the work (wholly unpaid, be it remembered) of my Colonial friends during these past twenty years, claims some consideration and some recognition You will see by the signatures that the authorities are the highest attainable.

Ozone.

WITH reference to a paragraph in NATURE, p 373, on observations of ozone in the atmosphere, and the paucity of observers and records, I may be allowed to state that I have collected sets in the North Atlantic and Pacific Oceans and Mediterranean These have been taken by officers of the Royal Navy and mercantile marine at sea, and some of the records have been tabulated, and may be communicated to some society in due course. Moffatt's papers, made by Negretti and Zambra, have been used throughout, so the observations are all uniform and comparable. W. G BLACK.

Edinburgh, February 19

LION-TIGER AND TIGER-LION HYBRIDS

THE Council of the Royal Zoological Society of Ireland entertain some hope that it will be possible to produce in their Gardens examples of hybrids or cross-breeds between the two largest species of cat, namely, the lion and tiger

That such hybrids have been produced is a matter of historical record, and as the writer is particularly inter-

ested in the success of the experiment now in progress in the Dublin Gardens, where over one hundred lion cubs have been successfully reared, he thinks it desirable to record all the details which he has been able to collect on the subject

So far as can be ascertained the only lion-tiger cubs, as they have been called, which were ever produced belonged to several distinct litters by different parents, perhaps, but in the same menagerie—that of F Atkins, of Windsor

The father of the first litter of these cubs was a lion bred in Atkins's menagerie, the head-quarters of which were at Windsor. The mother was an imported tigress From Griffith's account ("Animal Kingdom," vol ii p 448, 1827) it would seem that the lion and tigress were about two years together, in the same cage, before any issue appeared The first litter, consisting of three cubs, was born at Windsor on October 17, 1824—being the result of a particular intercourse which lasted for ten or twelve days in the beginning of the previous July The cubs were shortly afterwards exhibited to his Majesty, who, according to the showman's own handbill—a copy of which has been lent to me by Dr William Frazer—christened them lion-tigers The lion died six weeks afterwards, and the cubs, as related by Griffith, were fostered by several bitches and a goat, and it was expected would attain to maturity, but although there is no clear intimation as to the exact date when this was written, the figures of the cubs accompanying the account are said to represent them at the age of only about three months It is stated by one writer, however, that they did not attain to maturity ("English Cyclopædia Nat Hist," vol ii p 763, art "Felidæ," 1854)

The next litter was born at Edinburgh on December 31, 1827, according to Atkins's showbill and Sir William Jardine's works[1] There were two cubs, and it would seem that they were exhibited together with, and therefore probably reared by, the mother, in the same den, but whether she were the same tigress as the mother of the previous litter is not clear

They were seen by Sir William Jardine in September, 1828, and his figures may have been taken from them, but it has some resemblance in details, though not in general pose, to the figures published by Griffith of the 1824 litter It would seem that Sir William was under the impression that it was these very cubs which were subsequently exhibited together with their parents in the same cage in the autumn of 1829 But there is a difficulty in accepting this conclusion, because the stuffed specimens of these two cubs still exist—one in the British Museum (Natural History) and the other in the Science and Art Museum, Edinburgh. I have recently had opportunities of examining both, and I should be inclined to think that the cubs were not *more* than about nine or ten months old when they died So that either the cubs seen in 1829 were born subsequently to December 31, 1827, or the stuffed cubs just referred to must have been born previous to that date. That the cub in the British Museum was presented by J Atkins, of Windsor, is attested by Dr Gray's "Old List," page 40, which, through the courtesy of Dr Gunther, I have been able to consult.

That the specimen in Edinburgh was one of those born in 1827, and figured by Sir William Jardine, is, indeed, stated in the "English Cyclopædia," which adds that the cubs of that litter died young. Hence, it seems most probable that the cubs seen in the autumn of 1829 belonged to a subsequent litter, as has been suggested above. Further, Mr J G. Robertson, formerly of Kilkenny, has informed me that he saw a lion, tigress, and their three hybrid cubs in one cage in Kilkenny, where they were brought by a showman about the year 1832. They were the sole stock of the show.

[1] "The Menageries, Quadrupeds," Sir William Jardine (2nd edition), vol i, pp. 191, 192. 1830.

Accordingly, it seems that besides the definitely attested births of the years 1824 and 1827, there were also, probably, some others One of the accounts states that there is no great difficulty in promoting the union of the two species

Besides the cub already referred to as having been presented to the British Museum by J Atkins, I have also been shown by Dr Gunther unmounted skins of two reputed hybrid lion-tiger cubs, which are said in Dr Gray's list to have been purchased from a dealer named Mathur, in 1842 They cannot, I think, have survived more than two or three days after birth, and their markings are too indistinct to justify any special description, particularly as their parentage is not more definitely attested But it is of some importance to place on record here what is said as to the markings of the cubs first referred to The specimens in the British and the Edinburgh Museums are both somewhat faded In Gray's list the former is thus described "Hybrid cub between lion and tigress, yellow, back slightly waved, limbs and tail banded with black"

Sir William Jardine merely says the general colour was not so bright as that of the tiger, and the transverse bands were more obscure

Griffith describes the cubs he figured as follows —

"Our mules, in common with ordinary lions, were born without any traces of a mane, or of a tuft at the end of the tail Their fur in general was rather woolly, the external ear was pendant towards the extremity, the nails were constantly out, and not cased in the sheath, and in these particulars they agreed with the common cubs of lions Their colour was dirty yellow or blanket colour, but from the nose over the head, along the back and upper side of the tail the colour was much darker, and on these parts the transverse stripes were stronger, and the forehead was covered with obscure spots, slighter indications of which also appeared on other parts of the body The shape of the head, as appears by the figures, is assimilated to that of the father's (the lion); the superfineness of the body on the other hand is like that of the tigress" (p. 449)

Prof R H Traquair, F R S, keeper of the natural history division of the Edinburgh Museum, has kindly had a photograph taken of the specimen above referred to prepared for me, and the transverse markings are distinctly visible in this picture

I am tempted to conclude this record with an extract from Atkins's somewhat quaintly-expressed handbill, which does not bear any date, but probably belonged to the year 1828 The greater part of the bill consists of a long poetical description of the family with "a tigress their dam, and a lion their sire," and of the numerous distinguished persons who had paid them a visit The following prose portion will probably be sufficient to extract from what is possibly one of few still existing copies of the handbill

"ATKIN'S IMMENSE MENAGERIE

"Wonderful Phenomenon in Nature

"*The singular, and hitherto deemed impossible, occurrence of Lion and Tigress in one den*

"Cohabiting and producing young, again took place in this menagerie, on the 31st of December, 1827, at the City of Edinburgh, when the royal tigress brought forth two fine cubs!! And they are now to be seen in the same den with their sire and dam The first litter of these extraordinary animals were presented to our most gracious Sovereign, when he was pleased to express considerable gratification, and to call them lion-tigers, than which a more appropriate name could not have been given. The great interest the lion and tigress have excited is unprecedented, they are a source of irresistible attraction, especially as it is the only instance of the kind

ever known of animals so directly opposite in their dispositions forming an attachment of such singular nature Their beautiful and interesting progeny are most admirable productions of nature The group is truly pleasing and astonishing, and must be witnessed to form an adequate idea of them The remarkable instances of subdued temper and association of animals to permit the keeper to enter their den, and to introduce their performance to the spectators, is the greatest phenomenon in natural history"

V BALL

OBSERVATIONS OF ATMOSPHERIC ELECTRICITY IN AMERICA[1]

THE meteorological official of the United States known as "The Chief Signal Officer" has sanctioned the publication of this voluminous report of 320 quarto pages, embodying the result of a widespread photographic record and direct reading of atmospheric electrometers carried out under the auspices of the United States Government during the years 1884 to 1888, with the immediately utilitarian object of ascertaining how far it was possible to use electrical indication in weather prediction As Mr Mendenhall says, "No studies or investigations which did not bear upon this question were [considered] proper or allowable"

Although thus limited in scope the actual observations made and here recorded can hardly fail to be of service to future investigators into this obscure subject

The report begins with a historical introduction, in which it is admitted that electricity was first purposely drawn from the clouds in France by Buffon and D'Alibard about a month before Franklin tried his already projected experiment, and that de Saussure was one of the first to obtain fairly quantitative results and to detect a diurnal period

Volta "hit upon the capital device of a burning match" to replace the previous feeble collecting devices such as a bullet and wire shot up into the air But nothing really exact and continuous was done "until Sir W Thomson attacked the problem." He introduced the quadrant electrometer and the water-dropper, which have been the universal recording instruments ever since

In fact "the work of Palmieri on Mount Vesuvius constitutes perhaps the only extensive series of observations in which instruments founded on the original design of Sir W. Thomson have not been used"

In the States the first energetic and influential mover in the direction of a serious record appears to have been Prof Cleveland Abbé, who got himself authorised in 1880 by the Chief Signal officer to consult with Prof Rowland on the subject, and afterwards with Prof Trowbridge, and to make arrangements for a series of effective observations Under the auspices of these gentlemen a staff of observers were trained and suitable instruments obtained, tested, and improved Various collectors were tested, and in 1883 a photographic registration apparatus of M Mascart was put into operation. In 1884 Mr Mendenhall "was appointed to assume the direction of the work as chief of the physical laboratory and instrument division of the office in Washington" Stations were established in Washington, Baltimore, Boston, New Haven, Ithaca, and Ohio

Much work was done in connection with electrometers by McAdie and McRae, but this is incorporated in the article "Electrometer" of the "Ency Britt."

The instrument ultimately adopted was a quadrant electrometer of the Mascart pattern with special improvements, and was constructed by the Société Génevoise A picture of it is given.

[1] "Report of Studies of Atmospheric Electricity" By T C Mendenhall Extract from Memoirs of the National Academy of Sciences, 1889. (Washington.)

The method of connecting the quadrants to the two equal halves of a water battery, so that they might always be at equal opposite potentials, and of attaching the needle to the collector, was after many trials adopted, partly because higher insulation was thus possible, partly in order to get a straight line law Deviation from this, due to what is called the "electric directing couple," is not overlooked, but by a stiff suspension and small range it is minimised

An interesting chapter is that on "collectors" The water-dropper was mostly used, but its freezing is apt to interrupt the record "Sergeant Morrill experimented on a special flame collector," supplied with gas at constant pressure and arranged so that wind could not extinguish it, and "before the termination of the work obtained very satisfactory results" But in order to secure uniformity between different stations he also designed a mechanical collector—a clockwork machine with revolving arm and intermittent contacts, which is virtually a gigantic replenisher, utilising the atmospheric potential as an inductor, and thereby feeding the electrometer up to the same potential. It seems to be as quick in response as a water dropper (an important point, as some of the fluctuations of potential are very rapid), but "as it was only completed towards the end of the period of observation nothing very definite can be said of its performance" An illustration of the ingenious device is given in detail

Observations

Preliminary records are given showing the curves got at a roof station and a balcony station, also at different observatories in the same town Some also from the top of the Washington Monument, which naturally show far greater potential and changes than the instrument in the Signal Office

There are plotted a number of zigzags obtained from the different stations about the States, and very complicated and entangled the record is None of the stations show any agreement, and, particularly at Ithaca, the electrometers seem usually to have been in a wildly excited state

But during an Aurora on May 20, 1888, they were singularly quiet, and the remark is made "It will be observed that the indications of the electrometer were positive during the day and night, and that no unusual fluctuations occurred."

The atmospheric potential is usually positive, and it has been often thought that a change to negative signalised bad weather Certainly this does frequently happen, sufficiently often to make it worth while specially to examine this point; and several curve charts are given to show that "negative electricity in clear weather was observed at most if not all of the Signal Service Stations on numerous occasions during the progress of the work In many cases precipitation occurred at points 10 to 100 miles distant, but in others clear weather prevailed over almost the entire country A number of instances of negative potential during clear weather occurred at Ithaca, where careful attention was given to the matter of special observation by Mr. Schultze"

Effect of Dust, Haze, Fog

"The effect of dust, haze, smoke, &c, in producing negative potential has been noticed by more than one observer [Query whether the negative potential can have ever produced or permitted the haze —O. J L.] Several instances of the action of clouds of dust were noted by Sergeant Morrill at Boston On March 7, 1888, in the afternoon the potential was observed to fall rapidly from − 90 to − 270 upon the rising of an especially heavy cloud of dust, and similar phenomena were observed on April 7." "A fall of potential could be certainly predicted when a dust cloud was seen rising. On other days when high winds and dust clouds prevailed negative potential

was observed A figure is given of an observation at Terre Haute, Ind, on a day when a fog formed after sunset, and the potential then rapidly fell from + 1000 to − 200 volts" "The same phenomenon was frequently observed during the autumn when the formation of a haze or fog just as the sun was setting was a common occurrence"

The observer at Terre Haute (Sergeant McRae) wisely made special observations as to the possible effect of locomotives on a railway a quarter of a mile distant, but, so far as the recods show, the passage of a train, when not happening to coincide with a fog formation, did not seem to disturb the curves

Clouds and Wind

"The direct action of a cloud or group of clouds in producing a fall of potential was often observed" For instance the following at Boston — "In the morning of January 3, 1888, the potential had been steadily positive At 11 30 it was + 32 volts, from which it fell steadily at the approach toward the zenith of a small cumulus cloud, reaching − 21 volts As the cloud passed away the potential rose to + 6, again falling to − 31 as a large mass of cumulus clouds approached Later the sky became overcast, and the potential became steadily negative

"On June 7, at 5 30 p m, the potential fell from + 43 to − 173, and then rose slowly to its former value The rise and fall occupied fifteen minutes, and coincided with the appearance over the buildings to the west of a fleecy cirro-stratus cloud and its disappearance over the institute building in which the electrometer was located

"Again, on June 9 the potential was positive all day up to 5 p.m At that hour it fell from + 73 to − 113, then rising to + 52 The sky was nearly free from clouds, and the fluctuation coincided with the approach and departure of a cirro-stratus cloud, passing about 15° from the zenith The inductive action of the cloud was plainly suggested in all of these cases"

High wind also usually causes a drop of potential

Averages

Some charts are then given of average monthly potentials, showing nearly always positive average values, highest in the winter, lowest in summer

Some smoothed diurnal curves are also given, and "seem to indicate the existence of two principal maxima of potential in the day, and also in a general way that one of these occurs not many hours before noon and the other toward the latter part of the day"

Thunderstorms

Special attention was paid to the observations before, during, and after the occurrence of thunderstorms, but the needle then dashes wildly to either side, and sparks often begin to pass And the remark is made —"Aside from the general characteristics (rapidity and range of fluctuation) these potential curves seem to have little in common The examination of a few cases only might lead to interesting conclusions, which would almost certainly be overthrown by the study of a greater number. Sometimes the potential falls rather steadily until the violent movements begin, but sometimes it rises just as long and steadily. In many cases the fluctuations start from a high positive, while in many others the reverse is the case The storm is usually accompanied by precipitation; sometimes this begins before the needle starts on its series of swings from side to side, and sometimes these movements precede precipitation. The steady rise of potential for some hours immediately following a thunderstorm may mean that clear and fair weather is to be expected, but Fig. 71 is good evidence that it may also be interpreted to mean that another thunderstorm is just at hand."

"Although these records are somewhat unsatisfactory as far as throwing any light upon the nature of thunderstorms, it must not be forgotten that with a single exception [two stations at Washington] none of these storms have influenced more than one station The complete investigation of a storm would demand a large number of observing stations relatively near to each other, by means of which a full history of the potential changes about and in all parts of the storm could be obtained

"Such an examination might result in bringing order and system out of what seems at present little less than confusion"

Then follow many specimens of the actual photographic record at Baltimore on days when lightning occurred, and finally a mass of tables embodying abstracts of results at the different stations, and also some taken at Kew and Greenwich in England, though at both of these institutions the scale used appears to be arbitrary

General Conclusions

Among the conclusions the following may be noted "Instruments similar in every respect, separated by a distance of a hundred meters may give very dissimilar indications" (Not merely, it is explained, as regards *absolute* values only, which may be expected to disagree, but as regards fluctuations also) "Observers were instructed to study the appearance of negative electricity before and after and during precipitations, and at one time the hope was indulged in by the writer, as well as by several of the observers, that this phenomenon might afford great assistance in the prediction of local storms, rains, snows, &c, which offer so much difficulty in forecasting by present methods.

"Further observation and investigation, however, did not justify this expectation, serving rather to increase the meteorological conditions under which negative potential might be looked for, and to diminish the definition of relationship between it and precipitation That negative electricity is tolerably certain to be observed in connection with precipitation in a majority of cases is doubtless true, but it does not appear in such a way as to be of any value in forecasting"

Near the end of the historical introduction we learn with regret that the observations thus tabulated and discussed are now no longer going on

"In August, 1888, all observations were discontinued It was thought that a sufficient number had been accumulated to decide the question of their use in weather forecasting, and in fact their study up to that date gave little encouragement in that direction" "Many questions of great scientific interest had to be set aside for those likely to be of immediate practical value"

The amount of material thus rapidly accumulated, centralised, and well discussed, is typical of what can be done under efficient Government authorisation and by the head of a National Laboratory The carrying on of the research for immediate utilitarian ends, and stopping it as soon as it was seen that the results aimed at were not forthcoming, is perhaps also typical

It is to be hoped that some day the question will be reopened, and a fresh series of results obtained So far as I (who am by no means a meteorologist) can judge, I should surmise that a number of fairly concentrated stations over a large plain would be desirable, and also that the vertical gradient of potential should be attempted by a series of collectors at different altitudes on a tall mast, or possibly up a hill-side

Further, the general aspect of the curves seems to me to suggest that the instruments were almost too sensitive and not sufficiently dead-beat They should be quick in indication and at the same time thoroughly damped, so that the record shall contain as little as possible of any effect due to instrumental inertia Some very light

quartz-fibre instrument might be devised, and perhaps it might contain its own recording apparatus in a compact form, so as to make registration a much easier and less cumbrous business than it has been hitherto.

When so much is unknown it is a mistake to begin by observing with too great intricacy of detail. The salient features should be first obtained, and then attention directed to the minutiæ, but one of the first things to do is to arrange that every swing in the curve shall mean a swing of atmospheric potential, and not a mere excursion of a heavy needle

I hope that the energy, skill, and judgment of the various observers in the States, and of Mr Mendenhall, the author of this valuable report, may be utilised through the resources of the U S Government by the inauguration of a fresh series of observations under somewhat different conditions, and without the hamper of any immediately specified practical object OLIVER J LODGE

THE PRESERVATION OF THE NATIVE BIRDS OF NEW ZEALAND

IN our issue of September 16 last year (vol xlvi p 502) we printed an excellent memorandum drawn up by Lord Onslow, late Governor of New Zealand, relating to a proposal for the preservation of the native birds of that colony by setting apart two islands for this purpose, namely, Little Barrier or Hauturn Island in the north, and Resolution Island in the south As regards the first of these islands, we have lately received a copy of the report by Mr Henry Wright (addressed to the Hon John Ballance, Premier of New Zealand) upon the subject According to Mr Wright, Hauturn Island, in the Gulf of Hauraki, which is almost circular in shape, and contains an area of from 9000 to 10,000 acres, rising in the middle to an elevation of about 2000 feet, is very well adapted for the purpose required Writing with a thorough knowledge of all the north island, Mr Wright is able to say that there is no other part of it where the native birds are to be found in anything like such profusion and variety He gives a list of forty species to be met with within its limits, and mentions as particular varieties the stitch-bird or kotihe (*Pogonornis cincta*) and the large dark kiwi (*Apteryx bulleri*) as both found there There are slight difficulties in the way of the project, such as the presence of about a dozen Maoris now living on the island, and of a claimant for the timber, which, in the shape of kauri pine (*Dammara australis*), is present in large quantities There are no Weka Rails (*Ocydromus*) in the island to destroy the birds' eggs, and there are no bees, which, for some reasons, are considered to be highly inimical to the native birds in New Zealand The wild pigs, formerly numerous, have been killed out, and the mutton-bird (*Œstrelata gouldi*), the young of which were formerly eaten by the pigs, will consequently be able to breed again undisturbed Cats unfortunately are very numerous, but Mr. Wright proposes to offer at once a reward for their destruction, which is, of course, of great importance.

Mr Wright's report seems quite convincing as to the suitability of Hauturn Island for the object in view, but we regret to hear that some difficulties have arisen in the Parliament of New Zealand as to the appropriation of the funds required for the purpose.

Lord Onslow, however, is not disposed to let the matter drop, and will, we are sure, be strongly supported by Lord Glasgow, the present Governor of New Zealand, in carrying the matter to a successful issue. The Council of the Zoological Society of London, whose attention has been called to the subject, have passed in its favour the following resolutions, which were communicated to a general meeting of that body on the 16th inst

(1) The council of the Society have learnt with great satisfaction the steps that were proposed to be taken by the Earl of Onslow, when Governor of New Zealand, and by the Houses of General Assembly for the preservation of the native birds of New Zealand, by reserving certain small islands suitable for the purpose, and by affording the birds special protection on these islands

(2) The council much regret to hear that difficulties have been encountered in carrying out this plan as regards one of these islands (Little Barrier Island), and trust that the Government of New Zealand may be induced to take the necessary steps to overcome these difficulties and to carry out this excellent scheme in its entirety

(3) The council venture to suggest that besides the native birds to be protected in these reserves shelter should also be afforded to the remarkable Saurian, the Tuatera Lizard (*Sphenodon punctatus*), which is at present restricted to some small islands on the north coast of New Zealand, in the Bay of Plenty

These resolutions have been communicated to the present Governor of New Zealand, and will, we trust, be of some assistance to him in inducing his Ministers to carry this excellent scheme into execution

THE EARTHQUAKES IN ZANTE.

THE following is a list of the shocks of earthquake at Zante, compiled from telegrams published in the *Times* and *Standard* —January 31, at daybreak, the most destructive earthquake, of which, however, some warning must have been given, if we may judge from the comparatively small loss of life Other slighter shocks followed during the day February 1, 2 a m, another severe shock, felt also in Cephalonia. February 2, two more violent shocks, one of which caused some fresh damage. February 3, further shocks, but less frequent and violent February 5, another violent shock. February 6, continued shocks of slight intensity, followed by three more severe ones in the afternoon and evening. February 7, another violent shock in the morning, resulting in but little additional damage February 8, some slight shocks. February 10, some slight shocks in different districts February 11, 1 a.m, a somewhat severe shock, followed by a succession of shocks between 8 and 9 p m February 12, further shocks in the early morning, soon after midnight, and again at intervals during the day February 13 or 14, renewed slight shocks, accompanied by loud subterranean rumblings The Athens correspondent of the *Times*, telegraphing on February 20, says "The shocks of earthquake continue at Zante, with varying degrees of violence No serious damage is reported, but those who are compelled to live in the half-ruined or insecure houses are exposed to frequent alarms." It is estimated that the total loss of property due to the shocks may exceed £600,000.

According to a telegram in the *Times* for February 6, the tide in Venice on the evening of February 1 "ebbed so low as to leave several of the canals without water The gondola traffic was interrupted at different points, and many of those craft were stranded. This phenomenon corresponded with the earthquakes at Zante and Cephalonia." A simple calculation will show, however, that this can hardly have been due to the principal shock. The straight line joining Zante and Venice passes almost directly up the Adriatic, and its length is roughly 720 miles. Taking the time between daybreak on January 31 and the evening of Feb 1 at 36 hours, this would give for the sea-wave an average velocity of 20 miles an hour, corresponding to an average depth of about 30 feet, which is considerably less than the actual amount, the mean depth of the Adriatic being 110 fathoms.

Earthquakes are frequent in Zante, and sometimes very severe. One of the most destructive shocks, which occurred on October 30, 1840, is described by Ansted in

his work on the Ionian Islands (pp 415-419) chiefly from the report of the Lord High Commissioner, Sir Howard Douglas. The prison was in this case also unroofed, and hardly a house in the town of Zante escaped some injury All of the villages on, or bordering on, the plain suffered more or less, especially Sculikado, which was reduced to a heap of ruins The total amount of damage done was estimated at not less than £300,000 The great earthquake was followed by a large number of others, some very severe, ninety-five being counted up to November 4 Ansted notes (pp 368, 369) the curious fact that each of the Ionian Islands seems for the most part to have its own earthquakes, independently of the others About the year 1818, he says, all the sensible shocks in Cephalonia and Zante were tabulated, the record extending over two and a quarter years "During this time thirty distinct and well-marked shocks were recorded in Cephalonia, but in no case did the shocks in Zante, although nearly contemporaneous, absolutely coincide with them In most cases an interval of some days, and almost always more than twenty-four hours, seems to have elapsed between the times of the disturbances in the two, although they are so near that in these days [1863] of long range, a cannon-shot fired from the one might reach to the other"

NOTES

THE French Academy of Sciences has opened a subscription in support of the movement for the publication of the writings of Jean Servais Stas and the erection of a monument in his memory.

A MEETING of delegates of the Academies of Science at Berlin, Gottingen, Leipzig, Munich, and Vienna was held on January 29, under the presidency of Prof Ribbeck The object of the meeting was to prepare the way for a sort of federal union of the various German scientific societies, so that they may be able to act together about important matters of common interest A hope was expressed that a great international confederation of scientific societies might ultimately be formed

ANNOUNCEMENT has been made of the death, on February 2, 1893, at Hendaye, in the Department of the Basses Pyrénées, in his sixty-eighth year, of M Victor Aimé Léon Olphe Galliard, author, among other works, of "Contributions à la Faune Ornithologique de l'Europe Occidentale," in forty livraisons (of which the last was published in 1892) giving an elaborate description of the birds not merely of Western but of almost the whole of Europe, to say nothing of allied species belonging to other countries. M Olphe Galliard (whose name few writers, even Frenchmen, spell correctly) was remarkable among his countrymen for his knowledge of other languages than his own, and his recognition of the works of foreign ornithologists stands out in great contrast with that accorded to them by most continental authors. He translated into French several valuable papers written in Swedish and other tongues as little known, thus bringing them before readers to whom they would have been otherwise inaccessible, while he still further showed his appreciation of foreign naturalists by introducing into his principal work portraits of Johann Friedrich Naumann and William Macgillivray as the representative ornithologists of Germany and Great Britain. The earliest performance by which M Olphe-Galliard will be remembered was his description in the *Annales* of the National Society of Lyons for 1852 of the interesting Algerian bird which he called *Erithacus Moussieri*, after a French army-surgeon of that name who had recognised it as a new species in 1846. In the following year specimens of it were procured by the late Mr. Louis Fraser, and placed in the British Museum, but they met no kind reception there then, or even later, for the species finds itself in the *Catalogue of Birds* (vii. p 20) far removed from what all naturalists who have observed it in life declare to be its nearest relations—the Stonechats or the Redstarts—and shot into the rubbish-hole placarded *Timeliidæ*, where no one would ever think of looking for it. M Olphe Galliard's latest publication consisted of letters addressed to him by the somewhat eccentric Christian Ludwig Brehm, which appeared in the *Ornithologisches Jahrbuch* for 1892

A MEETING of conchologists is to be held at 67, Chancery Lane, on Monday, February 27, at 8 p m, for the purpose of founding a "Malacological Society of London"

THE Geologists' Association has arranged for a visit of the members to the British Museum (Natural History), Cromwell Road, on March 18, when Mr W Carruthers will give a demonstration on "Gymnosperms from the Devonian to the present time" There will be an excursion to Norwich, Cromer, and Lowestoft at Easter

SOME admirable suggestions for the guidance of teachers of evening classes in wood working under the direction of County Councils have been prepared by the Examination Board and Committee of the City and Guilds of London Institute The suggestions relate to drawing lessons, object lessons, and bench work lessons

THE type of weather during the past week has undergone but little change from that of the preceding week Anticyclonic areas lay over Scandinavia and Spain, and low pressure systems continued to skirt our north and west coasts The general conditions, however, were much quieter, although a deep depression reached the west of Ireland on Sunday, causing gales on our western coasts. On Tuesday a large and important disturbance arrived over the south-west of England from off the Atlantic, and the wind circulation around its central area was complete The difference of barometric pressure was, however, by no means large in different parts of the kingdom, and consequently there was not much wind The barometer fell as low as 28 7 inches over the centre of the cyclonic area, and later during the day the disturbance continued its passage across England, and was accompanied by heavy rain Temperature continued high for the season, the daily maxima ranging generally from 45° to 55°, while on Sunday, the 19th inst, the thermometer rose to 60° in the inland parts of England. In London it reached 59°, which was a higher reading than had been recorded so early in the year since 1878 The sky was exceptionally brilliant in the east and south-east on that day, but on the whole the air has been very damp throughout the week, and rainfall has been of almost daily occurrence For the week ended the 18th inst the rainfall exceeded the mean in all districts, except in the east of England. In the west of Scotland and the south-west of England the excess was considerable Bright sunshine only exceeded the normal amount in Ireland and the north and east of Scotland

THE Pilot Chart of the North Atlantic Ocean for February, 1893, shows that the weather in the North Atlantic during January was not abnormally severe, and that the eastern part of the ocean was unusually free from storms A map is given illustrating the great size and severity of the hurricane of December 22 last, which had moved rapidly from Hatteras in an east north-east direction. At the time selected for illustration, when the centre lay in longitude 36° west, the storm area covered the entire Atlantic from Labrador and Nova Scotia to Madeira, Portugal, and Ireland Some very low barometer readings were recorded, the lowest being 27 75 inches. There was a large amount of ice during January along the coast of

America, as far south as Hatteras; in Chesapeake Bay it was reported to be thicker than for twenty-five years.

THE official report of the International Meteorological Conference at Munich from August 26 to September 2, 1891, has now been issued. It contains protocols of the various meetings, with appendices and supplements.

THESSALY was supposed to have got rid of the plague of field mice, but it appears that the congratulations offered to her were somewhat premature. The Athens correspondent of the *Times* telegraphs that swarms of these troublesome creatures are beginning to reappear both in Thessaly and in the neighbouring district of Phthiotis. "It was hoped," he says, "that the severe cold and heavy rains of the last few months had exterminated them, but they seem to have taken refuge in the mountains, and are now returning in large numbers to the plains. The Prefect of Phthiotis has applied to the Government for instructions as to the best means of dealing with this destructive pest."

ACCORDING to a correspondent of the *Scotsman*, writing from Borthwickbrae, Selkirkshire, the mice pest in Scotland has greatly diminished, if it has not entirely disappeared, during the last two months. "The great abundance of owls," he says, "coupled with the very severe weather, has no doubt given them a check." During the severe storm of last month the owls, unfortunately, suffered also. The keeper at Alemoor Loch counted over thirty of the short-eared or heather owl, and eight kestrel hawks—some lying dead, others able to fly a few yards only, while several sat until lifted in the hands. The short-eared owls did not go to the woods to roost, which were close to the loch, but were in the willows and reeds along the edge of the loch.

SIR EDWARD BIRKBECK has accepted the presidency of the British Sea-Anglers' Society, which was founded recently at a meeting held in London. It is proposed that the Society shall have branches in all parts of the United Kingdom, and the members hope that they may be able not only to secure for themselves certain advantages in connection with their favourite sport, but to be of some public service. The chairman of the preliminary meeting, Mr. C. H. Cook, touched on the question of legislation for the protection of sea fish. "I hope," he said, "that the anglers will take up the cause of immature sea-fish. Already a movement, to which we may give a strong impetus, is rolling forward in this direction, but it is checked by the trawlers' interests. The harm done by these men is almost incalculable. I have seen their nets within a stone's throw of the shore, in less than three fathoms of water, where they scoop up and destroy the infant fish by the million. It may be that the evidence tendered by trustworthy members of the Sea-Anglers' Society may be the means of putting an end to inshore trawling. I hope it will. It often happens that the information given to the Fishery Boards is wilfully misleading, owing to it being given by fishermen, who fear they will lose their living."

THE Council of the Cremation Society of England, in its Report for 1892, expresses much satisfaction with the progress made by the cause which the Society represents. It seems that within the year no fewer than 104 bodies were cremated, "including a large proportion of individuals well known in society by their connection with art, science, or literature, or by a distinguished position of some other kind, ten having been members of the medical profession."

MR. A. H. S. LUCAS, who has edited the *Victorian Naturalist* admirably since it was started nearly nine years ago, has tendered his resignation in consequence of his election to the head-mastership of Newington College, Sydney. The Field Naturalists' Club, of Victoria, to which the magazine belongs, has expressed its cordial thanks to Mr. Lucas for his services. Mr. F. G. A. Barnard, who has been both secretary and librarian of the club, will act for the present as Mr. Lucas's successor.

A MOST interesting and suggestive paper on "pottery glazes: their classification and decorative value in ceramic design" was read by Mr. W. P. Rix at the meeting of the Society of Arts on February 7. It is printed in the current number of the Society's Journal. Mr. Rix tries to show that the relative merit of various glazes is based upon certain optical principles, which have only been partially examined by men of science, and that these principles, underlying the pleasurable sensations to the eye, really govern that which we are pleased to call good taste and excellence, so far as glazes are concerned, and are not mere matters of opinion. The reading of the paper was followed by a lively discussion, in the course of which Mr. Binns quoted a saying attributed to Mr. Gladstone, that a fine piece of glaze "feels like the touch of a baby's hand." Mr. Binns had often been struck with the aptness of the illustration. There was a peculiar soft texture in a fine piece of glaze that only a connoisseur could appreciate.

THE *Times* of Tuesday gives an account of a process by which anthracite coal bricks are now being manufactured. The bricks are made of grains of anthracite dust, which are forced to cohere by means of a special cementing compound and by great pressure. The coal dust is mixed with the binding material in the proportion of 96 per cent. of the former to 4 per cent. of the latter. The compound is fed into a mixer, where it meets a jet of steam, a stiff paste being formed, which is delivered successively into a series of moulds under a pressure of 25 cwt. As the mould plate revolves, the charge in each mould is brought between two rams, which exert a pressure of two tons per square inch on each side of the charge, forming a very dense and homogeneous coal brick. The brick, still in the mould, passes on to the delivery ram, by which it is pushed out on to a table, and is removed for the market. These coal bricks are said to make an excellent fuel and to possess a very high efficiency for steam-raising purposes. The *Times* thinks that with such a fuel at the disposal of the public there is room to hope for a reduction in the pollution of the atmosphere of towns, as well as a reduction in the coal bills of steamship companies and of steam users generally. It adds that the invention is being worked by the Coal Brick Syndicate, of 2, Trafalgar-buildings, Northumberland Avenue, London.

IT seems that serious depredations have been committed among the recently-discovered Phœnician tombs at Gebel Imtarfa, in Malta. The *Mediterranean Naturalist* says that the manner in which not only these tombs, but many others, have been rifled of their contents by irresponsible curiosity hunters, and the state in which many of the ancient ruins of the islands now are constitute a disgrace to European archæological science. More has been done to obliterate and destroy vestiges of Malta's ancient history during the last two centuries than was effected in the preceding two thousand years. Orders have been issued from head-quarters, Valletta, to the effect that the District Commanding Royal Engineer is to report immediately any discoveries of ancient tombs, burial places, or pottery that may occur in course of excavations for works, or come to light in any way; and that such objects are to be carefully preserved until they have been inspected by an officer of the Civil Government, and left untouched *in situ* until this inspection has been made.

A DISCUSSION on Mr. E. G. Carey's paper—to which we lately referred—on the bridges of the Manchester Ship Canal is

reported in the new instalment of the Transactions of the Institution of Engineers and Shipbuilders in Scotland. Mr Carey, in the course of his reply to the various speakers, alluded to the question as to the value of annealing steel. He said that, so far as his experience went, annealing steel certainly removed all stress. At the Forth Bridge they were very curious about this subject. They had a single strip of steel, which they strained up to some 30 times, to about 25 tons on the square inch. After every straining, it was annealed. That went on for days and weeks, and the steel seemed to be literally the same as when they started. The experiment grew wearisome, and ultimately, when the strain was run up inadvertently to about 30 tons per square inch, and the specimen finally broke, it was almost a relief, but it proved that the annealing of steel removed all strain, and that, although injured, if annealed, it seemed to recover its former properties.

A VALUABLE synonymic and bibliographical catalogue of the New Zealand land and freshwater Mollusca, by H. Suter, was communicated to the Linnean Society of New South Wales at its meeting on December 28. In 1880 Prof. Hutton, in his "Manual of the New Zealand Mollusca," enumerated 125 species of land, fresh, and brackish water molluscs. Since then zoology has made such rapid strides that this fauna is raised in Mr Suter's catalogue to a total of 178 species, divided by him into 45 genera. The land mollusca embrace 142 species, of which 15 are operculate; the fluviatile shells are reckoned at 32, 12 being bivalves and 7 operculate univalves. This large addition of one-third to the list of twelve years ago is not the greatest advantage the present catalogue has over its predecessor; numerous species are now removed which, by the negligence of collectors or the errors of European authors, were formerly included among the shells of New Zealand. The attention bestowed during the last decade upon the anatomy of the New Zealand snails has furnished data for a more natural classification, while the increase of colonial libraries has facilitated the quotation of fuller references than were previously available.

MR J. M. STAHL, Illinois, has much to say in the *American Agriculturist* about the virtues of wood ashes. Speaking of them as a medicine for farm animals, he says he has found them of great value. He has raised swine rather extensively for more than twenty years without cholera or swine plague, and has not lost one per cent. of his hogs from disease. He keeps wood ashes, and charcoal mixed with salt, constantly before his swine in a large covered box with holes two-by-six inches near the bottom. The hogs will work the mixture out through these holes as fast as they want it. He selects ashes rich in charcoal, and mixes three parts of ashes to one of salt. There is no danger of the swine eating too much of this mixture, or of pure salt, if it is kept constantly before them, and they are provided with water. The beneficial effects of the mixture are quite marked, especially when the hogs are fattened on fresh maize. A little wood ashes, given to horses, is also, he maintains, very beneficial. In thirty-seven years' experience upon the farm he has lost but one horse, and this was overheated in the horse-power of a threshing-machine during his absence, and the only "condition powder" he has ever used has been clean wood ashes. The ashes may be given by putting an even teaspoonful on the oats twice a week, but he prefers to keep the ashes and salt mixture constantly before the horses, and has made for it a little compartment in one corner of the feed box. His experience is that the best condition powder is a mixture of three parts wood ashes to one of salt; and that when it is given regularly, and reasonable care and intelligence are used in handling the horse, no other medicines are necessary. Mr. Stahl has also great faith in the efficacy of wood ashes as a fertiliser.

A VALUABLE paper on the industrial resources of the Caucasus, by an Austrian official, Herr G. Sedlaczek, is summarised in the Board of Trade Journal for February. Dealing with the silk industry, the author says that the Russian Government has spent more money for the furtherance of this department of trade than for any other industrial purpose in Caucasia, and that the results are in no way commensurate with the trouble and outlay. Although the country possesses innumerable mulberry trees, in some parts forming veritable forests, and excellently suited for feeding silkworms, although the climatic conditions are favourable, and the inhabitants have from time immemorial been familiar with the working up of the raw material, the most untiring efforts of the Government have proved little else than a struggle to preserve the mere existence of the silk culture and industry. The estimated production of silk in Transcaucasia at the present day is 36,000 pouds, although in 1855 it was 30,000 pouds. The average value of the produce is said to be about 6,000,000 roubles. Considerable advance has been made in reeling, spinning, and twisting; new foreign machinery is everywhere at work, and all that is wanting is a good raw material, the production of which is, however, being constantly prevented, on the one hand by disease in the worms, and on the other by the indolence of the producers. The Russian demand for silk is far from covered by native production, silk being annually imported to the value of about 12½ millions of roubles, while the exports amount only to about 3,000,000 roubles in value. In spite of protective duties the imports are increasing while the exports are decreasing.

MANY marine animals (radiolaria, ctenophora, &c.) rise and sink slowly in the water, having some means, apparently, of changing their specific gravity. This has been recently studied by Herr Verworn (*Pflüger's Archiv*), in the case of *Thalassicolla nucleata*, a radiolarian about the size of a pea. It has a central capsule with nucleus, a coarse endoplasm, a vacuole-layer, a gelatinous layer, and ray-like processes. As a rule, these animals float at the surface. They sink on seizing food heavier than themselves, also when strongly stimulated by shaking, or by chemical agents. It was found that the central capsule and the gelatinous layer are both heavier than sea water, while the vacuole layer is lighter. On being stimulated, the pseudopodia (or processes) were drawn into the vacuole-layer, and the protoplasm also retired from this, the walls of the vacuoles flattening from without inwards, till at length very little of them was left. Then the animal began to sink. At the bottom the vacuoles were soon regenerated, and the animal rose again. Thus it appears that the vacuole layer is the hydrostatic apparatus of these organisms, the vacuole liquid being that part of the cell which is lighter than sea water, and keeps the cell at the surface. The same probably holds good with other pelagic animals. That the vacuole liquid is lighter than the sea-water from which it comes is no difficulty, since it is known that living protoplasm is impermeable for many salts.

A VOLUMETRIC method for determining the amount of chromium in a specimen of steel has become a great metallurgical desideratum since the good qualities conferred upon steel by its addition have become generally known. Such a method is described by G. Giorgis, of the University of Rome, in the *Atti* of the *Accademia dei Lincei*. It is founded upon the formation of potassium chromate and hydrated manganese sesquioxide on adding a solution of potassium permanganate to a solution of sesquioxide of chromium in potassium hydrate. Ten grammes of the steel are dissolved in a mixture of sulphuric and nitric acids (3 to 1), the solution is made up to 1 litre with distilled water, and 250 c.c. are made just alkaline with sodium hydrate, and treated with hot permanganate of potash till the solution assumes a red colour. After cooling the whole is

poured into a flask of 500 c c capacity, filling up with water. 400 c.c. are filtered through a dry filter, acidified with sulphuric acid, reduced by SO_2, and concentrated to 200 or 100 c c, according to the quantity of chromium probably present Donath's method may then be employed, consisting in the addition of the chromium salt prepared as above described, to a measured quantity of a standard permanganate solution, and watching for the golden yellow colour assumed by the mixture when the permanganate is all dissolved, *i e* when all the chromium exists in the form of a chromate, from which the amount of chromium is easily calculated It is said that this process is extremely accurate, and requires only a small fraction of the time required by gravimetric methods

THE subject of dew appears to be still involved in some controversy. An experimental contribution to it has been recently made by Herr Wollny (*Forschungen*, &c), who used plants in glazed pots with earth of varying moisture, some of these being allowed to radiate freely on favourable nights, while others were screened The following is a brief outline of Herr Wollny's views .—Dew depends partly on evaporation from the ground, partly on transpiration. It is at present doubtful whether precipitates from the air share in it or not A cloudy sky weakens the cooling process without stopping it wholly With copious radiation, the temperature minimum is at the surface of the plant-covering (of the ground), and here the aqueous vapour rising from the warm ground is partly precipitated With increase of the ground-heat downward there is increase of the water brought up by the plants, which is given up as vapour and condensed The more moisture there is in the ground, the more water is evaporated from the ground and the plants Dew formation is usually favoured by the larger number of stomata on the under surface of leaves than on the upper On a given surface of ground the dew is more plentiful the stronger the plant organs above ground, and the closer the plant growth The temperature of still air increases from the surface to a certain limit (at about 5 feet over grass it was sometimes 4° or 5° C. warmer than on the ground) In experiments with blotting paper, cotton wool, feathers, and asbestos, the first was much moistened, while the others showed dew in drops Bodies of organic origin attract more moisture than those of mineral (a case of hygroscopic absorption). For vegetation, the author considers the benefit of dew but trifling Of the whole annual precipitation at Munich dew only gave 3 23 per cent.

WITH the present year the weekly *Botanische Zeitung* enters on the fifty-first year of its existence, and Graf zu Solms Laubach gives with the first number of the year an interesting sketch of its history, uninterrupted for half a century, even during the stormy period of 1847–1849 The inception of the undertaking was due to the suggestion of a botanist still living, Dr Carl Müller, of Halle The first number of the *Botanische Zeitung* appeared on January 9, 1843, under the editorship of Von Mohl and Schlechtendal. The editorial chair has been occupied since then by some of the most distinguished German botanists, De Bary, Hallier, Kraus, Jost, and the present editors, Solms-Laubach and Wortmann

DR. VINES, the Professor of Botany in the University of Oxford, has for some time past had in preparation a "Student's Text book of Botany," which will be more comprehensive than his edition of Prantl's well-known "Elementary Text-book." It is to be fully illustrated, and is expected to be ready early in the autumn of this year. It will be published by Messrs. Swan Sonnenschein and Co.

MESSRS GAUTHIER-VILLARS ET FILS, Paris, continue to issue the useful series of small volumes called "Encyclopédie Scientifique des Aide-Mémoire." The following volumes have lately been added: "Corderie," by M Alheilig, "Formation des Gîtes Métallifères," by L. de Launay, "Le Grisou," by M. Le Chatelier, "Moteurs à Vapeur," by M Dudebout; "Détente Variable de la Vapeur," by A Madamet, "Canons, Torpilles, et Cuirasses," by A. Croneau, "Textiles Végétaux," by H. Lecomte, "Essais d'Or et d'Argent," by H Gautier, "État Actuel de la Marine de Guerre," by L. E Bertin, "Industrie des Cuirs et des Peaux," by Ferdinand Jean.

THE "Annuaire," for 1893, of the Royal Observatory of Belgium, by F Folie, has been published This is the sixtieth year of issue

THE Department of Science and Art has issued the volume for 1893 containing its calendar, history, and general summary of regulations

IN the course of an elaborate investigation recently published in the *Zeitschrift fur Hygiene*, December 9, 1892 ("Die Aetiologie des infectiosen fieberhaften Icterus" (Weil'sche Krankheit), Jaeger draws attention to the dangers which may arise from bathing in polluted water Already in 1888 Pfuhl (*Deutsche militar-arztl Zeitschrift*, 1888, Heft 9 and 10) attributed an outbreak of typhoid fever, accompanied by jaundice, which occurred amongst the garrison stationed at Altona to bathing in the Elbe, which at the time was described as more than usually polluted. Hueber and Globig came to similar conclusions with regard to outbreaks of the above "Weil'sche Krankheit," which appeared at Ulm on the Danube and Lehe respectively Jaeger has made a special study of the cases which arose amongst the soldiers at Ulm, and has endeavoured to trace, if possible, the infection to its source It was found that the military bathing place was situated below the point where the Danube is joined by the highly-polluted river Blau. This stream is described as being practically an open sewer, and even before it reaches Ulm is stated to be grossly contaminated in its flow through the small village of Soflingen It was further ascertained that in this village for many years a mysterious disease had been rife amongst the ducks and geese, whilst fowls were also occasionally attacked, and that moreover it was a common custom to throw the dead carcases of these animals into the Blau as the readiest means of getting rid of them A careful examination of some of the birds which had succumbed to this disease revealed the constant presence of a micro-organism, which Jaeger asserts was identical with that found repeatedly and isolated in the cases of icterus investigated by him at Ulm It is further stated that by mixing some of the highly-polluted Blau water at Soflingen with sterile broth, and inoculating it into white mice, they were killed in sixteen hours, and that the organism, which was found abundantly present in various organs of the body, was in every respect identical with that previously isolated in the cases of icterus at Ulm, and from the carcases of the birds at Söflingen. Taking these various results into consideration Jaeger is of opinion that they afford very strong evidence of the virus of this disease having been introduced into the highly contaminated stream at Soflingen, and conveyed thence to the military bathing-place, which, as already mentioned, is situated below the junction of the Blau with the Danube In consequence of the appearances in cultivations to which this organism gives rise, the author has suggested for its name *Bacillus proteus fluorescens*, and claims in it to have discovered the exciting cause of the so-called "Weil'sche Krankheit," the etiology of which is attracting much attention on the continent.

NOTES from the Marine Biological Station, Plymouth :— Heavy gales have prevailed for many weeks, confining operations to the inshore waters. The week's captures include numbers of the Archiannelid *Dinophilus taeniatus*, of the Polychaeta *Marphysa*

sanguinea and *Sagalion boa*, and of the Nudibranch *Ancula cristata* In addition to the forms mentioned last week, the townettings have contained the Siphonophore *Muggiæa atlantica*, the Anthomedusa *Margellium* (*Lizzia*) *octopunctatum*, and several ephyræ of *Aurelia*, together with numbers of Teleostean ova, Prosobranch and Opisthobranch veligers, larval Lamellibranchs and *Cyphonautes*-larvæ The Polychæte *Cirratulus cirratus* and Gastropod *Littorina littoralis* are also breeding

THE additions to the Zoological Society's Gardens during the past week include a Vervet Monkey (*Cercopithecus lalandii*) from South Africa, presented by Mr. Walter Neall; two Red and Yellow Macaws (*Ara chloroptera*) from South America, presented by Mr Henry Goschen; a Herring Gull (*Larus argentatus*) European, presented by Mr W R Galbraith, a Bar-breasted Finch (*Munia nisoria*) from Java, presented by Mr Sydney D Birch, two Whooper Swans (*Cygnus musicus*) European, purchased, a Vulpine Phalanger (*Phalangista vulpina*), three Barbary Mice (*Mus barbarus*) born in the Gardens

OUR ASTRONOMICAL COLUMN

COMET BROOKS (NOVEMBER 19, 1892).—The following ephemeris for Comet Brooks is taken from *Astronomische Nachrichten*, No 3142.—

1893	R A. (app) h m s	Decl (app) ° ′
Feb. 23	0 31 49	+24 18 2
24	33 0	23 59 8
25	34 9	23 42·1
26	35 17	23 25 0
27	36 24	23 8 5
28	37 30	22 52 4
March 1	0 38 34	22 36 8

COMET HOLMES (1892 III).—Several communications with respect to the late appearances of this comet are inserted in the Comet Notes of *Astronomy and Astrophysics* for February, among which will be found one by Prof E Barnard Observing with a 12-inch on the night of January 16, at 8h 10m, he found that an estimation of the comet's diameter gave 30″, while a setting of the wires indicated 29″ 4 While under observation "*the comet seemed to be perceptibly brightening*," and further measurements at 9h 45m gave a diameter of 32″ 4 At this time he says "The nucleus had developed clearly, and was very noticeable as a small, ill-defined star" With the 36 inch, which he was able to use later, he made the following measures, which we reproduce here, as they are quite unique in showing the increase in diameter of a comet due evidently to some external impact —

Standard Pacific time h m	Diameter ″
10 29	43 4
10 30	44 9
10 31	43 6
10 42	47 8
10 43	47 9
10 45	46 0
11 13	47 3
11 15	46 1

In concluding his remarks he says · "This is certainly the most remarkable comet I have ever seen, taking everything into consideration"

The following is the ephemeris for this week:—

Greenwich, Midnight

SOLAR OBSERVATIONS AT ROME.—In the *Memorie Degli Spettroscopisti Italiani* for January, Prof Tacchini communicates the observations made at the Royal College with respect to the various phenomena observed at the solar surface during the third trimestre of 1892. Dealing first with the prominences the total number for each of the months are respectively for north latitudes, 182, 129, 120, total 431, and for south latitudes 141, 167, 185, the total number here amounting to 493 The balance here is in favour of the southern hemisphere for greater frequency, but a curious fact may here be remarked, and that is that the maxima for the north and south latitudes occur in the months of July and September respectively, each exceeding considerably the number of prominences recorded for the same month in the opposite hemisphere.

The greatest frequencies occurred in latitudes (+60° +70°) and (−50° −60°) The groups of spots seem to have predominated slightly in the southern latitudes, the record showing 49 against 41, at the equator as many as 13 for zone (0° +10°) were seen, the zone (0° −10°) showing only 4, the relative frequency occurred here in the same zones in both hemispheres (±10° ±20°)

With reference to eruptions, the month of July contains the only records, six for the northern, and three for the southern hemisphere, four of these taking place in zone (+10° +20°)

Prof Tacchini also has a note on the great prominence of November 16 last, in which he describes in detail the numerous observations which he was fortunate to procure. Although one can gather a good idea of the rapidity of the ascent from the table, the figures which accompany it show in a striking manner the great changes of shape that was such a conspicuous feature in its ascent. At 9h 0m on the 16th the height was only 131″ 8, but at 1h it had reached 319″ 2, and at 1h 35m, 534″ 3, thus being its maximum height It is interesting to notice the numbers showing the increase of altitude in *one* minute of time.

For instance, at 11h. 55m the increase of altitude per minute was 0″ 56, at 1h 4m it was 6″ 75, decreasing from this value to 4″ 34 at 1h 27m At 1h 32m the velocity of ascent was increased, the value amounting to 9″ 72, but at 1h 34m the increase of altitude reached its maximum, 20″ 80, showing the ascent per minute.

THE STAR CATALOGUE OF THE "ASTRONOMISCHE GESSELSCHAFT"—The Harvard College Observatory has now completed the task of cataloguing the zone of stars undertaken in connection with the great catalogue of the *Astronomische Gesselschaft* The stars included number 8627, and lie between 49° 50′ and 55° 10′ north declination, and the positions are reduced to the epoch 1875. Most of the observations were made by Prof Rogers during the years 1870–1884, and the reductions have throughout been in his charge. The publication appears simultaneously as vol xv part ii of the *Annals of the Harvard Observatory*, and as one of the volumes of the *Gesselschaft* All concerned are to be congratulated on the completion of the zone, which involved over twenty-six thousand observations and an immense amount of calculation

NOVA AURIGÆ.—Mr Fowler draws attention to the fact that the nova is still as bright as ninth magnitude, and therefore easily visible in comparatively small telescopes. Its spectrum seems to consist of the two bright nebula lines near wave lengths 5006 and 4956 The latter is only slightly fainter than that at 5006.

PARALLAX OF β CYGNI.—Mr Harold Jacoby, whose work on the reduction of the Rutherford photographic measures of the stars about β Cygni we have previously referred to, suggests in *Astronomical Journal*, No. 287, that the discrepancies in the results can be explained on the hypothesis of a parallax of β Cygni amounting nearly to a whole second of arc To investigate this he has chosen five pairs of comparison stars, from which he has computed the parallax from each pair separately by "using the difference of the distances of the two comparison stars from β as the quantity from whose variation the parallax should appear;" in this way he has obtained the weighted mean for the parallax to be + 0″·97, a value which, if endorsed by further observations will show us that of all stars β Cygni is one of our nearest neighbours.

GEOGRAPHICAL NOTES

MR. G. B. GRUNDY, of Brasenose College, the student in geography appointed jointly by the University of Oxford and the Royal Geographical Society, has made a careful survey of the battlefield and site of the town of Platæa and of Leuctra,

in Greece. He is now engaged in preparing a comprehensive memoir on the subject which may be expected to throw new light on some questions of historical geography

MR MACKINDER, in his fifth lecture for the Royal Geographical Society's education scheme, spoke of the chief lines of communication between Asia and Europe and the ways by which successive bands or hordes of Asiatic invaders forced a passage into the heart of Europe The routes across Asia Minor from the Gate of Cilicia to the northern waters, and the thoroughfare through the Balkan peninsula now traversed by the international railway, were shown to have guided the movements of peoples and the formation or dissolution of nations from the dawn of European history on to the present day.

THE United States appears to have entered the field as an aggrandising power, taking up territory beyond the limits of the continent of North America. The annexation of Hawaii seems likely to be effected without remonstrance, and a footing has also been obtained in San Domingo, the eastern part of the island of Haiti

MR A. VAUGHAN WILLIAMS has been exploring the region round the mouth of the Sabi River in south-east Africa He has ascended the stream for thirty miles to the limit of tidal influence

THE orthography of African place names is a perpetual source of confusion It appears that in place of Zimbabwe or Zimbabye we ought, in order to render the sound of the word used by the people surrounding the ruins, to write "Zimbabghi" The familiar name Mashonaland is in itself a corruption of the native name, but is always pronounced Mashunaland, a pronunciation to which the spelling ought to conform.

RAILWAYS seem likely at last to become established in China The line from Teintsin to Taku has now been extended to the River Lan, a total distance of 130 miles, and is being rapidly pushed northward, a considerable section being already opened for passenger traffic.

CAPTAIN BOWER'S JOURNEY IN TIBET

AT an extra meeting of the Royal Geographical Society, on Monday night, Captain H Bower described his recent journey with Dr Thorold across Tibet from west to east They set out from Leh on June 14, 1891, and were fortunate enough to get well into Tibet before meeting any natives. Travelling due east they crossed a pass of 18,400 feet, on the other side of which lay the Horpa Cho, the highest lake yet met with in Tibet, and probably the highest in the world, its altitude being 17,930 feet Along the route eastward many other lakes were passed, all salt and without outlet, the want of fresh water being sometimes severely felt, a kettleful of hailstones was a welcome catch on one occasion The travellers used ponies and donkeys for carrying their loads, as yaks do not eat grain, and grass was often not met with for many days' journey At length, after travelling east and south-east for about 700 miles, they were stopped within 200 miles of Lhasa by the Tibetans, who paid no attention to Chinese passports, and after much parleying insisted on a complete change of route The party had to retrace their steps for several days' march, turn northward, and then make their way east at a safer distance from the capital It was now the month of October and the crossing of passes over 18,000 feet, with temperatures of 15° or more below zero, in strong wind was extremely trying About the end of November, for the first time for four months, the tents were pitched at a less altitude than 15,000 feet, and soon afterwards Chiamdo was reached Here great difficulty was experienced with the lamas, who insisted that no European should enter the town; but by the intervention of the Chinese Amban, whose power was really but slight, the party was allowed to proceed, passing round the outside of the town. From Chiamdo to Batang the way was easy, and no difficulties were experienced thereafter At Ta-Chen-Lu they entered China and reached Shanghai on March 29, 1892 Throughout Central Tibet the authorities disclaimed the sovereignty of China, maintaining that only the grand lama had jurisdiction in that region. Many of the lamas met with were educated and intelligent men, but not inclined to give information. Much difficulty was experienced in getting the names of lakes and mountains, no two Tibetans giving the same answer. The fanaticism and distrust of the people created constant difficulties, but Captain Bower, under the pretext of being a Buddhist with a peculiar ritual, succeeded in making observations for position openly as part of a religious service, previous attempts to do so by stealth having failed.

THE CHEMISTRY OF OSMIUM.

AN important addition to our knowledge of the chemical nature of this interesting element is contributed by Prof Moraht and Dr Wischin, of Munich, to the current number of the *Zeitschrift fur Anorganische Chemie* Two years have scarcely elapsed since the position of osmium in the periodic system was finally decided by the painstaking re-determination of its atomic weight by Prof Seubert Previous determinations of the atomic weight of osmium had been made with material which Seubert subsequently showed to be impure, and in consequence the erroneous value, 198 6, had been ascribed to it Indeed previous to the year 1878 the order of precedence as regards atomic weight of the four metals of the platinum group —gold 196 2, iridium 196 7, platinum 196 7, and osmium 198 6 —was entirely at variance with the order demanded by their chemical and physical properties, and a standing contradiction of the periodic law of Newlands and Mendeleef In that year, however, Seubert attacked the case of iridium, and as the result of a series of determinations, made with the laborious care which has characterised all his work, the atomic weight of this metal, when obtained in a pure state, was shown to be 192 5, a number very different to that previously assigned to it, and which was afterwards remarkably confirmed, even to the decimal place, by an independent investigation by Joly Three years later Seubert made his celebrated re-determination of the atomic weight of platinum, which resulted in the number 194 3 being finally derived for the true atomic weight of the perfectly pure metal This value was likewise subsequently confirmed by Halberstadt In the year 1887 the position of gold was decided by simultaneous independent re-determinations of its atomic weight by Thorpe and Laurie in this country and Kruss in Germany, the two values being practically identical, 196 7 Lastly, in 1891, Seubert completed his work by re-determining the atomic weight of osmium with a specimen of the metal of practically perfect purity, with the result that the old number, 198 6, was found to be entirely erroneous, due to considerable quantities of impurities being present in the samples previously employed, and that the real value of this constant was 190 3, thus removing osmium from its former situation at the end of the series and placing it in its proper position at the head of it

The order of precedence of the metals of the platinum group is therefore as follows —Osmium 190 3, iridium 192 5, platinum 194 3, and gold 196 7. This order is in full accordance with the relative chemical and physical properties of these metals, and the last outstanding exception to the periodic generalisation has disappeared

Although the properties of pure metallic osmium, and particularly its atomic weight, are now known with certainty, the nature of its compounds is yet very little understood Moreover, it is evident from the result of the investigation of Prof. Seubert that previous workers have been dealing with an impure metal of atomic weight, 198 6. It was therefore desirable that not only should the chemistry of this element be extended to compounds hitherto uninvestigated, but that the composition and properties of the compounds already known should be subjected to a re-examination

Prof Moraht and Dr Wischin have therefore taken up the study of the compounds of osmium with oxygen, sulphur, and the halogens, employing material of a very high degree of purity, and the results of their investigation are both novel and interesting.

Work with osmium compounds is endowed with peculiar personal danger to the chemist, owing to the great facility exhibited under the most various conditions for the formation of the tetroxide OsO_4, a substance which boils at 100° C, and is very volatile at the ordinary temperature, and which attacks the skin, the lungs, and particularly the eyes with most serious consequences.

The material started with was a comparatively pure sample of the best known salt containing osmium, potassium osmate, $K_2OsO_4.2H_2O$. This salt was further purified by distillation

with nitric acid or aqua regia and absorption of the liberated tetroxide vapours in a solution of caustic potash The dark brown solution of potassium perosmate thus formed was largely diluted with water, and reduced to osmate by the addition of alcohol. After the expiration of about twenty-four hours almost the whole of the osmium had separated in the form of beautiful little crimson octahedrons of the salt $K_2OsO_4\ 2H_2O$, which, after washing with dilute alcohol, proved to be quite free from impurity, showing no trace of iridium

Previous observers have noticed that an aqueous solution of *potassium osmate*, K_2OsO_4, is most remarkably affected by sun light, a rapid decomposition being brought about with deposition of a black precipitate to which the composition $OsO_2\ 2H_2O$ has been ascribed The specimens experimented with, however, undoubtedly contained iridium, and it was therefore of interest to investigate the action of sunlight upon solutions of the pure salt just described When the crimson octahedrons of pure $K_2OsO_4\ 2H_2O$ were dissolved in cold water, and the clear red dish violet-coloured solution was exposed to direct sunshine, no evidence of change was apparent for several days, but the moment the vessel containing the solution was immersed in a bath of boiling water, while in bright sunshine, decomposition commenced, and a black precipitate rapidly accumulated, until after the expiration of two or three hours the whole of the osmium present was deposited As there is a marked tendency for the production of the noxious fumes of osmium tetroxide during this decomposition of the hot osmate solution by the waves of light it is best to take the precaution of reducing their amount to a minimum by the addition of a little alcohol, which acts as a strong reducing agent under these circumstances, and by passing a stream of hydrogen through the solution during the whole operation The precipitate is usually so finely divided that considerable difficulty is experienced in separating it from the solution The filtration succeeds best when the filter is previously moistened with dilute acetic acid, when a clear colourless filtrate is usually at once obtained The precipitate cannot be dried in a warm air bath, as it is largely converted thereby into the volatile osmium tetroxide It may safely, however, be dried over phosphoric anhydride in the vacuum of an air pump.

The accurate analysis of an insoluble substance of the nature of this precipitate, and containing a metal such as osmium, which so readily oxidises to the volatile tetroxide, is a task of exceptional difficulty The usual method of reduction to metal in a stream of hydrogen is insufficient, for more or less of the tetroxide is always formed during the process, necessitating the use of an absorption apparatus containing a solution of caustic potash, placed in front of the tube containing calcium chloride to absorb the water formed The difficulty is, then, how to estimate the small quantity of osmium thus dissolved in the large excess of alkali It was eventually found that the weak electric current from three Daniell's cells precipitates the whole of the osmium from such a solution, contained in a nickel dish which forms the negative electrode, in the form of pure *osmium dioxide*, OsO_2, which may conveniently be dried *in vacuo* over phosphoric anhydride and weighed as such.

By this mode of analysis the interesting fact was eventually elicited, that the black insoluble substance formed by the action of light upon a hot solution of potassium osmate is not, as was previously supposed, a hydrate of osmium dioxide of the composition $OsO_2\ 2H_2O$, but is no other than free *osmic acid* itself, the hydrate of osmium trioxide, $OsO_3\ H_2O$ or H_2OsO_4 Osmic acid is thus formed by the direct action of water, under the influence of sunlight and slight rise of temperature, upon the potassium salt This remarkable change is expressed by the simple equation.

$$K_2OsO_4 + 2H_2O = H_2OsO_4 + 2KOH$$

The liquid, as soon as the change commences, is observed to exhibit a strong alkaline reaction, becoming, as indicated in the equation, a solution of caustic potash It is singular that the presence of alcohol and the passage of a current of hydrogen during the reaction do not cause any reduction, serving only to hinder the further oxidation to the state of tetroxide Indeed, if the crimson octahedral crystals of potassium osmate are covered in sunshine with warm alcohol and a current of hydrogen is allowed to bubble through the liquid, no trace of blackening is observed upon the faces of the crystals. The moment water is added, however, decomposition is immediately brought about.

Osmic acid, H_2OsO_4, is a soot-black powder, which fumes strongly in moist air, owing to its rapid conversion into the volatile osmium tetroxide, OsO_4, but which is quite permanent at the ordinary temperature when preserved under water containing alcohol It dissolves readily in nitric acid with formation of the hydrate of osmium tetroxide, the so-called per-osmic acid Cold hydrochloric acid attacks it but very slightly Upon warming, however, it is entirely soluble, forming an olive-green liquid, which will be subsequently considered, with liberation of a small quantity of chlorine Sulphuric acid does not attack it Osmic acid reacts in a most energetic and interesting manner with sulphuretted hydrogen gas Even in the dry state at the ordinary temperature the reaction proceeds with considerable violence If the experiment is conducted in a piece of combustion tubing, upon which a bulb has been blown for the reception of the osmic acid, the moment that the gas enters the tube the whole of the black powder immediately becomes incandescent, and drops of water and a large quantity of free sulphur are deposited in the portion of the tube not heated by the reacting substances The residual product of the reaction is a brown powder, which has been found to be a hydrated oxysulphide of osmium of the composition $2OsSO\ H_2O$

The reaction occurs in accordance with the equation—

$$2H_2OsO_4 + 4H_2S = 2OsSO\ H_2O + 5H_2O + 2S$$

This *oxysulphide of osmium* is soluble in acids with decomposition, even sulphuric acid decomposing it with evolution of sulphuretted hydrogen It possesses acid properties, for it liberates carbon dioxide from carbonate of soda and sulphuretted hydrogen when fused with sulphide of potassium It would, moreover, appear to contain SH groups, for it yields mercaptan upon treatment with soda and ethyl iodide, the osmium being reduced to the dioxide OsO_2. Its probable constitution is therefore represented by the graphic formula —

$$\begin{array}{l} \mathrm{Os}\begin{cases}\diagup \mathrm{SH} \\ = \mathrm{O} \\ \diagdown \mathrm{O}\end{cases} \\ \mathrm{Os}\begin{cases}\diagup \mathrm{O} \\ = \mathrm{O} \\ \diagdown \mathrm{SH}\end{cases} \end{array}$$

When this oxysulphide is warmed in dry sulphuretted hydrogen another violent reaction occurs, the whole mass again becomes incandescent, and the whole of the oxygen is eliminated in the form of water The product of this second reaction with sulphuretted hydrogen is pure *osmium disulphide* OsS_2.

$$Os_2O_3(SH)_2 + 2H_2S = 2OsS_2 + 3H_2O$$

Of the *halogen* compounds of osmium only the chlorides have been at all investigated, chiefly by Claus, whose observations may be summarised in a few words

When finely-powdered metallic osmium is heated in a stream of dry chlorine sublimates are formed The first chlorine compound formed is chromous green in colour, but is only produced to a very slight extent There is next deposited a dense black sublimate, and finally a smaller quantity of a sublimate of the colour of red lead None of these three chlorine compounds are crystalline. Claus subsequently stated that the lowest chloride $OsCl_2$ is a bluish-black solid when isolated, and forms a dark bluish-violet solution, the sesquichloride Os_2Cl_6 is reddish-brown in the solid state, and gives with water a rose-red coloured solution, and the dichloride $OsCl_4$ is the compound which exhibits the colour of red lead, and yields a lemon-yellow solution

These observations of Claus are completely confirmed by the experiments of Prof Moraht and Dr Wischin, who, however, have extended them, and have been able to isolate other and higher chlorides of osmium

They commenced by warming a large quantity of the free osmic acid above described for two days upon a water-bath with concentrated hydrochloric acid, the flask in which the reaction was conducted being connected with an upright condenser A little alcohol was added in order to prevent the formation of osmium tetroxide The osmic acid eventually entirely dissolved with formation of the dark olive green coloured solution previously incidentally mentioned, a little chlorine being evolved at the commencement of the operation It was found impossible to evaporate the solution upon the water bath without decomposition, but evaporation *in vacuo* over sulphuric acid and solid caustic potash, the latter to absorb the hydrochloric acid, succeeded admirably. The solid left after complete evaporation consisted of well formed crystals which assumed the habit of six-sided pyramids. These crystals were dark olive-green in colour when moist, but when the last traces of superfluous water were removed, exhibited a bright vermilion colour. They were readily

soluble in water and alcohol, the solutions being coloured dark green, and the salt may be recrystallised from these solvents Upon analysis they were found to consist of the chloride Os_2Cl_7 crystallised with seven molecules of water

This chloride of osmium, $Os_2Cl_7 7H_2O$, would appear to be a molecular compound of the *trichloride*, $OsCl_3$, and the *tetrachloride*, $OsCl_4$ For when potassium chloride solution is added to the solution of the crystals in alcohol, a precipitate of brilliant red octahedrons and cubes of potassium osmichloride, K_2OsCl_6, is obtained, showing the presence of *osmium tetrachloride*, $OsCl_4$ Moreover, when the precipitate is separated by filtration, and the filtrate concentrated by evaporation *in vacuo*, dark green crystals of the *trichloride*, $OsCl_3$, are deposited containing three molecules of water of crystallisation

During the reduction of these crystals of the trichloride in a current of hydrogen for the purposes of analysis, a small quantity of a white sublimate was obtained, which probably consisted of the *octo-chloride*, $OsCl_8$, corresponding to the tetroxide OsO_4

Bromine does not react with osmium with anything like the energy of chlorine The free elements do not appear to combine at all, even at moderately high temperatures. Only a small quantity of a sublimate of a dark brown colour is obtained by passing bromine vapour over osmic acid This sublimate dissolves to a brown solution in water, which, however, rapidly decomposes with deposition of a black precipitate

When osmic acid, H_2OsO_4, is treated with hydrobromic acid in the manner just described in the case of hydrochloric acid a similar reaction occurs with formation of a clear reddish-brown solution which yields, upon evaporation *in vacuo* over sulphuric acid and solid caustic potash, small crystals of a molecular compound of the *tribromide*, $OsBr_3$, and the *hexabromide*, $OsBr_6$, together with six molecules of water of crystallisation. These crystals of $Os_2Br_9 6H_2O$ are dark reddish-brown in colour and exhibit a beautiful metallic lustre They are quite stable when preserved in a dry atmosphere, but rapidly deliquesce in moist air

Iodine appears to possess even less affinity for osmium than bromine When, however, osmic acid is treated with hydriodic acid a deep greenish-brown solution is obtained which deposits *in vacuo* dark violet rhombohedrons, exhibiting a brilliant metallic lustre, consisting of the anhydrous *tetra-iodide of osmium*, OsI_4 This iodide, the only one containing osmium yet prepared, is permanent in a dry atmosphere at the ordinary temperature, but rapidly deliquesces like the bromide when exposed to moist air

In relative stability the chloride bromide and iodide of osmium above described exhibit a gradation such as would be expected from the relations between the halogen elements themselves The iodide is readily dissociated by slightly raising the temperature, and upon the addition of water is decomposed with the deposition of a black precipitate containing the metal A similar decomposition occurs, although much more slowly, in case of the bromide. The chloride, however, is well-nigh permanent under these conditions, only exhibiting traces of decomposition after the lapse of a considerable time

A E TUTTON

REDUCTION OF TIDAL OBSERVATIONS[1]

THE tidal oscillation of the ocean may be represented as the sum of a number of simple harmonic waves which go through their periods approximately once, twice, thrice, four times in a mean solar day. But these simple harmonic waves may be regarded as being rigorously diurnal, semi-diurnal, ter-diurnal, and so forth, if the length of the day referred to be adapted to suit the particular wave under consideration The idea of a series of special scales of time is thus introduced, each time-scale being appropriate to a special tide For example, the mean interval between successive culminations of the moon is 24h. 50m., and this interval may be described as the mean lunar day. Now there is a series of tides, bearing the initials M_1, M_2, M_3, M_4, &c, which go through their periods rigorously once, twice, thrice, four times, &c., in a mean lunar day. The solar tides, S, proceed according to mean solar time, but, besides mean lunar and mean solar times, there are other special time scales appropriate to the other tides

The process of reduction consists of the determination of the mean height of the water at each of twenty-four special hours, and subsequent harmonic analysis. The means are taken over such periods of time that the influence of all the tides governed by other special times is eliminated.

The process by which the special hourly heights have hitherto been obtained is the entry of the heights observed at the mean solar hours in a schedule so arranged that each entry falls into a column appropriate to the nearest special hour Schedules of this kind were prepared by Mr Roberts for the Indian Government [1] The successive rearrangements for each sort of special time were made by recopying the whole of the observations time after time into a series of appropriate schedules The mere clerical labour of this work is enormous, and great care is required to avoid mistakes.

All this copying might be avoided if the observed heights were written on movable pieces But a year of observation gives 8760 hourly heights, and the orderly sorting and resorting of nearly 9000 pieces of paper or tablets might prove more laborious and more treacherous than recopying the figures.

The marshalling of movable pieces might, however, be reduced to manageable limits if all the twenty-four observations pertaining to a single mean solar day were moved together, for the movable pieces would be at once reduced to 365, and each piece might be of a size convenient to handle

The realization of this plan affords the subject of this paper, and it appears that not only is all desirable accuracy attainable, but that the other requisite of such a scheme is satisfied, namely, that the whole computing apparatus shall serve any number of times and for any number of places.

The first idea which naturally occurred was to have narrow sliding tablets which should be thrown into their places by a number of templates It is unnecessary to recount all the trials and failures, but it will suffice to say that the slides and templates would require the precision of a mathematical instrument if they are to work satisfactorily, and that the manufacture would be so expensive as to make the price of the instrument prohibitive

The idea of making the tablets or strips to slide into their places was accordingly abandoned, and the strips are made with short pins on their under sides, so that they can be stuck on to a drawing board in any desired position. The templates, which were also troublesome to make, are replaced by large sheets of paper with numbered marks on them to show how the strips are to be set The guide sheet is laid on a drawing board, and the pins on the strips pierce the paper and fix them in their proper positions

The strip belonging to each mean solar day is divided by black lines into 24 equal spaces, intended for the entry of the hourly heights of water The strip is nine inches long by ¼ inch wide, and the divisions (⅜ by ¼) are of convenient size for the entries There was much difficulty in discovering a good material, but after various trials artificial ivory, or xylonite, was found to serve the purpose Xylonite is white, will take writing with Indian ink or pencil, and can easily be cleaned with a damp cloth It is just as easy to write with liquid Indian ink as with ordinary ink, which must not be used, because it stains the surface

The observations are to be treated in groups of two and a half lunations or 74 days A set of strips, therefore, consists of 74, numbered from 0 to 73 in small figures on their flat ends

If a set be pinned horizontally on a drawing board in vertical column, we have a form consisting of rows for each mean solar day, and columns for each hour The observed heights of the water are then written on the strips.

When the twenty-four columns are summed and divided by the number of entries we obtain the mean solar hourly mean heights The harmonic analysis of these means gives the mean solar tides But for evaluating the other tides the strips must be rearranged, and to this point we turn our attention

Let us consider a special case, that of mean lunar time. A mean lunar hour is about 1h 2m m.s time, hence the 12h. of each m s day must lie within 31m. m.s. time of a mean lunar

[1] "On an Apparatus for facilitating the Reduction of Tidal Observations." By G H Darwin, F R S, Plumian Professor and Fellow of Trinity College, Cambridge. A paper read before the Royal Society on December 15, 1892

[1] An edition of these computation forms was reprinted by aid of a grant from the Royal Society and is sold by the Cambridge Scientific Instrument Company, but only about a dozen copies now remain.

hour. The following sample gives the incidence to the nearest lunar hour of the first few days in a year:—

Mean solar time d	h		Mean lunar time d	h
0	12	=	0	12
1	12	=	1	11
2	12	=	2	10
3	12	=	3	9
4	12	=	4	8
5	12	=	5	8
6	12	=	6	7
7	12	=	7	6
&c			&c	

The successive 12h of m s time will march retrogressively through all the twenty four hours of m lunar time

Now, if starting from strip 0, we push strip 1 one division to the left, strip 2 two divisions to the left, and so on, the entries on the strips will be arranged in columns of approximately lunar time.

The rule for this arrangement is given by marks on a sheet of paper 18 in broad; these marks consist of parallel numbered steps or zigzags showing where the ends of each strip are to be placed so as to bring the hourly values into their proper places.

At the end of a lunation mean solar time has gained a whole day over mean lunar time, and the 12h solar again agrees with the 12h lunar. On the guide sheet the zigzag which takes its origin at the left end of strip 0 has descended diagonally from right to left until it has reached the left margin of the paper, and a new zigzag has begun on the right margin

When the strips are pinned out following the zigzags on the sheet marked M, the entries are arranged in 48 columns but the number of entries in each column is different The 48 incomplete columns may be regarded as 24 complete ones, appertaining to the 24 hours

Harmonic analysis of the 24 means of the complete columns gives the required tidal constants It must be remarked, however, that as the incidence of the entries is not exact in lunar time, investigation is made in the paper of the corrections arising out of this inexactness

The explanation of the guide sheet for lunar time will serve, *mutatis mutandis*, for all the others

The zigzags have to be placed so as to bring the columns into exact alignment, and printers' types provide all the accuracy requisite

To guard against the risk of the computer accidentally using the wrong sheet, the sheets are printed on coloured paper, the sequence of colours being that of the rainbow The sheets for days 0 to 73 are all red, those for days 74 to 74 + 73, or 147, are all yellow, those for days 148 to 148 + 73, or 221, are green, those for days 222 to 222 + 73, or 295, are blue, and those for days 296 to 296 + 73, or 369, are violet

Thus, when the observations for the first 74 days of the year are written on the strips all the sheets will be red, the strips will then be cleaned, and the observations for the second 74 days written in, when all the guide sheets will be yellow, and so on.

The paper also gives another considerable abridgement of the process of harmonic analysis, which is independent of the method of arrangement just sketched

In the Indian computation forms the mean solar hourly heights have been found for the whole year, and the observations have been rearranged for the evaluation of certain other tides governed by a time scale which differs but little from the mean solar scale. It is now proposed to break the mean solar heights into sets of 30 days, and to analyse them, and next to harmonically analyse the 12 sets of harmonic constituents for annual and semi annual inequalities By this plan the harmonic constants for 11 different tides are obtained by one set of additions. In fact, we now get the annual, semi annual, and solar elliptic tides, which formerly demanded much troublesome extra computation A great saving is secured by this alone, and the results are in close agreement with those derived from the old method.

An abridged method of evaluating the tides of long period MSf, Mf, Mm, is also given The method is less accurate than that followed hitherto, but it appears to give fairly good results, and reduces the work to very small dimensions

The advantages of the method proposed in the present paper may be best realized by a comparison of the amount of work entailed in the reduction of a year's tides as it has hitherto been carried out by the Indian Survey at Poona, and what it will be under the new method

It has been usual in the Indian reductions to use three digits in expressing the height of water, and there have been fifteen series, or even more It follows from a simple multiplication that the computer has had to write 394,000 figures in reducing a year of observation This does not include the evaluation of the annual and semi annual tides, so that we may say that there have been about 400,000 figures to write

It is now proposed to express the heights by two digits, and they only have to be written once, and the number of figures to write is 17,500, accordingly the writing of 382,000 figures is saved

In the old method the computer had to add together all the digits written, say, 394,000 additions of digit to digit

It is now proposed to use twenty four hourly values in three series, viz S, M, and MS, and twelve two hourly values in eight others, and the number of additions comes to 123,000 Thus 270,000 additions are saved

We may say that formerly there were about 800,000 operations (writing and addition), and that in the present method there will be about 140,000 This estimate does not include a saving of several thousands of operations in obtaining the tides of long period It may therefore be claimed that the work formerly bestowed on one year of observation will now reduce at least five years, and that the results are equally trustworthy

The manufacture of the computing strips of xylonite is rather expensive, but as it formerly cost in England rather more than £20 to reduce a year of observation, the cost of the apparatus will be covered by the saving in the reduction of a single year, and it will serve for any length of time

The apparatus, together with computation forms, will be on sale with the Cambridge Scientific Instrument Company at a price of about £8

It is proper to mention that Dr Borgen has devised and used a method for attaining the same end as that aimed at in this paper He has prepared sheets of tracing paper with diagonal lines on them, so arranged that when any sheet is laid on the copy of the observations written in daily rows and hourly columns, the numbers to be summed are found written between a pair of lines This plan is inexpensive and has considerable advantages, but the chance of error is no doubt increased by the fact that the lines of addition are diagonal, and because figures seen through tracing-paper are comparatively faint

THE HARVARD COLLEGE OBSERVATORY

THE forty seventh annual report of the director of the astronomical observatory of Harvard College, for the year ending October 31, 1892, by Prof E C Pickering, has been issued. We reprint the following passages —

The number of photographs taken with the eight inch Draper telescope is 2777 The number taken in Peru with the Bache telescope is nearly two thousand, of which 601 have been received in Cambridge The examination of these plates has as usual led to the discovery of a large number of interesting objects. Ten variable stars, U Delphini, S Pegasi, T Aquarii, R Crateris, R Carinæ, S Canis Minoris, S Carinæ, R Ophiuchi, X Ophiuchi, and Espin's variable star in Auriga in addition to the thirty seven previously announced have the hydrogen lines bright in their spectra. Seven new variable stars have been discovered this year by means of this property The number of stars of the fifth type has been increased by eight, making the total number now known of these objects forty five The hydrogen line F was shown to be bright in the spectra of six stars in addition to those already known Photographs have been obtained of the spectra of eight planetary nebulæ showing bright lines The spectrum of the nebula surrounding thirty Doradus is unlike that of other gaseous nebulæ The star A G C 20,937 has a somewhat similar spectrum Five stars have been shown to have spectra of the fourth type All of these peculiarities have been detected by Mrs Fleming except in the cases of one of the known variables, one of the planetary nebulæ, and two of the stars of the fourth type, which were found by Mr A E Douglass, in Peru, before the plates were sent to Cambridge

The amount of valuable material accumulated with these instruments is continually increasing, and has proved useful in many cases in studying the history of newly discovered objects.

The brightness for several years past of stars suspected of variability has been furnished to various astronomers. Plates have been sent to the Lick and Amherst Observatories and to the Smithsonian Institution for special investigations From one of them a new variable star in Aries was discovered by Prof Schaeberle It is hoped that this use of our plates may increase in the future A large number of photographs were taken of the new star in Auriga An examination of the older photographs showed that the region containing it had been photographed eighteen times from November 3, 1885, to November 2, 1891, and that it was then apparently fainter than the thirteenth magnitude It appeared upon five plates taken between December 16, 1891, and January 31, 1892 After its discovery it was photographed on sixty five chart plates and thirty six spectrum plates, until April 6, when it became too faint to be visible in the encroaching twilight All of these plates have been carefully studied and measured Twenty one charts and fifteen spectrum plates of this object have been taken since its reappearance in September, 1892 On these last plates, the spectrum is shown to resemble that of a planetary nebula

Many photographs of the lunar eclipse of November 15, 1891, were taken both at Cambridge and at the Boyden observing station near Arequipa, Peru The examination of these photographs for the detection of a possible lunar satellite led only to a negative result

The number of photographs taken with the 11 inch Draper telescope is 996 They include 372 spectra of β Aurigæ to determine the law of periodic doubling of the lines 244 of these images show the lines double so that the separation can be measured In like manner 208 spectra of ζ Ursæ Majoris have been photographed, and in 49 of them the lines are separated widely enough to be measured A similar study has been made of the new star in Auriga, of β Lyræ, of 11 Monocerotis, and of some other stars having peculiar spectra Photographic charts have also been obtained of numerous variable stars, stars having large proper motion, clusters and stars having peculiar spectra to determine their parallax if it is perceptible

Boyden Department

In establishing the fund that bears his name, Mr Boyden desired to secure an astronomical station where the effects due to the atmosphere would be greatly diminished This has now been successfully accomplished in the Harvard Station at Arequipa, Peru, where the effect of the air is no longer as heretofore the principal obstacle to progress in astronomy Instead of this the limit is now the size and excellence of our instruments A great advance would probably be made in our knowledge of the planets, and perhaps of the fixed stars, if a telescope of the largest size could be mounted under such favourable conditions.

This station has continued in charge of Prof. W. H Pickering The instruments chiefly employed have been the 13-inch telescope, the 8 inch Bache telescope, and a photographic camera having an aperture of $2\frac{1}{2}$ inches The first of these instruments has been largely devoted to visual work, for which unusual advantages are afforded by the transparency and steadiness of the air at this station Many interesting results have been derived from the observations made of the moon and various planets The observations of the moon relate to Plato and other regions, which have been carefully examined, and also to the systems of bright streaks visible at full moon The markings of Mercury have been studied, and this investigation appears to confirm Schiaparelli's view that the rotation of Mercury on its axis occupies the same time as its revolution in its orbit Although this planet appears to have no atmosphere, the markings upon it are very faint compared with those upon the moon Venus was micrometrically studied near its inferior conjunction with regard to its diameter, polar compression, and the refractive effect of its atmosphere. No permanent markings could be detected An extensive series of observations was made upon Mars The relative positions of 92 points upon its surface were determined by the micrometer. More than forty minute black points were discovered, provisionally designated as lakes The polar compression of the planet was measured, and appeared to be greater than that indicated by theory, which may be due to an excess of cloud in the equatorial regions The presence of the dark and narrow streaks called canals by Schiaparelli has been confirmed and various measurements of them have been made The clouds projecting beyond the limb, and terminator, discovered at the Lick Observatory, have been studied, and their height has been found to be at least twenty miles The relative colours of different portions of the planet have been minutely observed Two large dark blue areas have been detected, and other portions have been noticed to be subject to gradual changes of colour

Many new double stars were found in a survey of the heavens south of 30°, between 12h. and 18h The August occultation of Jupiter was observed both visually and photographically, as was also the new star in Auriga and Swift's comet, the photographs of which showed detail not noticeable in the visual observations.

With the camera, having the aperture $2\frac{1}{2}$ inches, very satisfactory photographs have been obtained of the Magellanic clouds, showing their composition to be partly of stars and partly of nebulous matter, also the spiral structure of the larger of the two clouds

Meteorological observations are regularly carried on Stations have been established at Mollendo, 100 feet above sea level, at La Joya, the elevation of which is 4,150 feet, at the observing station, 8,060 feet high, at the Chachani Ravine 16,650 feet high, where numerous miscellaneous observations have been made Notwithstanding the great height of the last named station, it can be reached by a mule path, and a hut has been erected where the observers can pass the night A survey of the Arequipa valley and neighbouring mountains has been made, depending on two separate base lines The heights of the mountains have been measured, and in some cases the result has been checked by a mercurial barometer.

The Bruce Photographic Telescope

This instrument, which if successful will be in many respects the most powerful in the world, is now rapidly approaching completion The eight surfaces of its objective have been ground and polished so that it could be tested on a star The results were satisfactory, although, of course, no definite opinion can be formed until the final corrections are applied The focal length proved to be that desired within half of one per cent Plans have been made and the foundations laid for a one story brick building with a sliding roof, in which it will be erected during its trial in Cambridge After this it is proposed to send it to the Arequipa station in Peru

Photographs have been taken with the transit photometer on 192 evenings, and when clear, throughout the entire night With this instrument images are obtained of all stars brighter than the sixth magnitude which cross the meridian during the night The value of this work was illustrated when the new star in Auriga was discovered in February, 1892 It then appeared that this object had been photographed on twelve nights since December 10, 1891, while no trace of it was visible on thirteen plates covering this region and taken before December 2, 1891 The only knowledge that exists of its changes of light during the six weeks in which it remained undiscovered is furnished by these photographs and those taken with the 8-inch telescopes It was also photographed with the transit photometer on twelve nights after its discovery Of the forty thousand standard stars of the tenth magnitude about eight thousand have been selected by Miss E F Leland during the past year, making eleven thousand in all

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—In the Chemical Department Prof. Odling is lecturing on the glucoses, Mr Fisher on inorganic chemistry, Dr. Watts on organic chemistry, and Mr. Veley on physical chemistry. There are about sixty students working in the laboratories, and a few of the senior men are engaged in research.

Among the apparatus belonging to the late Duke of Marlborough, presented by the Duchess, are three large spectroscopes by Hilger, one having five prisms, another being a direct vision spectroscope 5 feet 6 inches in length, two balances by Deleuil, a mercury pump by Alvergniat, Dumas' vapour density apparatus, Thomson's electrometer gramme machine, large Rhumkorf coil and a quantity of valuable glass apparatus. There are besides a number of specimens of compounds of rare earths

The Regius Professor of Medicine has placed his pathological

laboratory under the direction of the lecturer in Pharmacology Dr Ritchie of Edinburgh is carrying out in it some researches in Bacteriology The Chemical Club started last term by some of the senior men continues to hold meetings weekly for the discussion of recent chemical investigations. Mr. Ingham of Merton is secretary The meetings are well attended and useful.

Mr R T Günther, B A, Demy of Magdalen College, has been elected to the Naples Biological Scholarship for the ensuing year.

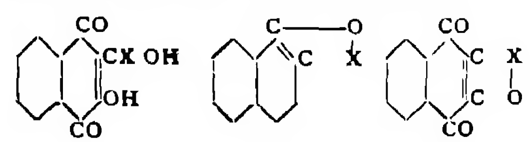
CAMBRIDGE.—Mr H Bury, Fellow of Trinity College, has been appointed by the Board for Biology and Geology to the use of a table at the Naples Zoological Station for March and April, 1893.

The Boards for Biology and Geology, and for Physics and Chemistry, have reported in favour of extending to Part I of the Natural Sciences Tripos the plan already adopted for Part II., namely, the substitution of distinct papers in each scientific subject, instead of papers each of which contains questions in all the subjects They propose that the change come into operation in 1894.

SOCIETIES AND ACADEMIES

LONDON

Chemical Society, January 19 —Prof A Crum Brown, President, in the chair —The following papers were read — Glucinum, Part I The preparation of glucina from beryl, by J Gibson The methods at present in use for preparing pure glucina from beryl are tedious and difficult to apply on the large scale, as the mineral, which contains but a small quantity of glucinum, has to be reduced to a very fine powder before being treated by the reagents usually employed for the decomposition of refractory silicates The author has worked out a process which greatly facilitates the preparation of glucina. If the coarsely ground beryl is heated in an iron vessel with six parts of ammonium hydrogen fluoride, complete decomposition occurs below a red heat The product contains the aluminium and most of the iron as insoluble fluoride and oxide respectively, together with glucinum fluoride, which dissolves on extraction with water In order to remove the last traces of iron from crude glucina, advantage is taken of the fact that the precipitation of a lead or mercuric salt by ammonium sulphide effects by mass action the complete separation of small quantities of iron which may be present in the solution —The determination of the thermal expansion of liquids, by T E. Thorpe The author describes various improvements in the ordinary dilatometrical method of determining the thermal expansion of liquids Amongst these the most important is the application of a device frequently employed in the construction of standard thermometers, and consisting in enlarging the bore of the dilatometer stem at some point On such an instrument the positions of the 0° and 100° points may be determined irrespectively of its range, and the thermometer, and the column of liquid in the dilatometer stem may be totally immersed in a bath of moderate size, thus doing away with corrections for the emergent columns of the two instruments. The methods of constructing, calibrating, and using the dilatometers are described, together with the baths employed in heating them —The determination of the thermal expansion and specific volume of certain paraffins and paraffin derivatives, by T E Thorpe and L M Jones The authors give the data relating to a number of hydrocarbons, alcohols, ketones, and other derivatives of the paraffins. The results show a fairly satisfactory agreement, in most cases, with the values calculated by Lossen's formula, but all the observed specific volumes, with the exception of that of propionic anhydride, differ considerably from those calculated by means of Kopp's values.—The hydrocarbons derived from dipentene dihydrochloride, by W A. Tilden and S Williamson The dihydrochloride, $C_{10}H_{16}2HCl$ melting at 50°, prepared by the action of moist hydrogen chloride on optically active turpentine, is known to be identical with that obtained from the active citrenes (limonenes) or from inactive "dipentene." On heating it with aniline, an oil is obtained which has hitherto been supposed to consist essentially of dipentene, on oxidising it, however, a certain proportion of aromatic acids is obtained. These acids are not formed on oxidising the active limonenes or pure dipentene with nitric acid; their formation in the previous case is, however, satisfactorily explained by the authors, who find that the dipentene obtained from the dihydrochloride contains large proportions of cymene, terpinene, terpinolene, and a small quantity of a saturated paraffinoid hydrocarbon boiling at about 155° —Sulphonic derivatives of camphor, by F S. Kipping and W J Pope The authors have succeeded in preparing camphorsulphonic acid, $C_{10}H_{15}O\ SO_3H$, a compound hitherto unknown, by the direct action of anhydrosulphuric acid or chlorosulphonic acid on camphor The acid is purified by the conversion of its sodium salt into camphorsulphonic chloride, $C_{10}H_{15}O\ SO_2Cl$, the latter substance is apparently obtained in optically different modifications which are separated only with considerable difficulty The sulphonic chloride is readily hydrolysed on boiling with water, yielding the sulphonic acid from which a series of well-defined salts has been obtained The action of anhydrosulphuric acid on bromocamphor results in the formation of bromocamphorsulphonic acid, this on suitable treatment yields a sulphonic chloride, $C_{10}H_{14}BrO\ SO_2Cl$, which crystallises in magnificent colourless octahedra, melting at 136-137° A bromocamphorsulphonic chloride of similar composition has been previously described by Marsh and Cousins as a "black, semi-crystalline tar," a repetition of their work shows this to be merely an impure form of the substance now described. The corresponding chlorocamphorsulphonic chloride described by Marsh and Cousins as a "microcrystalline, black solid," crystallises in massive colourless octahedra when pure, it melts at 123-124°, and has a specific rotatory power $[\alpha]_D = +110°$ The authors describe a number of salts and derivatives of these sulphonic acids —The preparation of dinitro-α naphthylamine $[NH_2\ NO_2\ NO_2 = 1\ 2\ 4]$ from its acetyl and valeryl derivatives, by R Meldola and M O Forster Meldola's process of preparing dinitro α naphthylamine from α acetnaphthalide having been questioned, the authors have re investigated the method and confirm it in all respects, they give full working details of the process, and show that the same product is obtained by the nitration and subsequent hydrolysis of valeronaphthalide —Thionyl bromide, by J Hartog and W E Sims. Thionyl bromide is obtained as a heavy, crimson liquid by the action of sodium bromide on thionyl chloride, its colour is possibly due to impurity At 150° the bromide decomposes, yielding bromine and sulphur bromides —Desulphurisation of the substituted thioureas, by A E Dixon. The monosubstituted thioureas are all de ulphurised on boiling with an alkaline solution of a lead salt, the same is true of disubstituted thioureas containing benzenoid groups, but not if such groups be absent. The tri- and probably also the tetra substituted thioureas are not de sulphurised under similar conditions A number of new thioureas are described.—Salts of active and inactive glyceric acid the influence of metals on the specific rotatory power of active acids, by P F Frankland and J. R Appleyard. The authors have prepared and analysed a number of salts both of inactive and dextro-glyceric acid; the solubilities and specific rotatory powers are also given Certain remarkable numerical relations apparently exist between the rotations of many of the salts, these should have considerable bearing on the vexed question of multiple rotation, and will be discussed after they have been submitted to a more detailed investigation.—Dibromo-β lapachone, by S C Hooker and A D Gray. Monobromo-β lapachone cannot be converted into dibromo-β-lapachone by the action of bromine alone; the formation of the latter derivative in the preparation of monobromo-β-lapachone from lapachol, is due to the production and subsequent decomposition of an additive compound of monobromo-derivative and hydrogen bromide —The conversion of para- into ortho-quinone derivatives, by S C Hooker. Both in the lapachol and other groups, compounds derived from a naphthaquinone, of the type represented by formula I, are far more readily converted, by the action of acids, into anhydrides derived from β-naphthaquinone (II) than into anhydrides of the α quinone type (III)

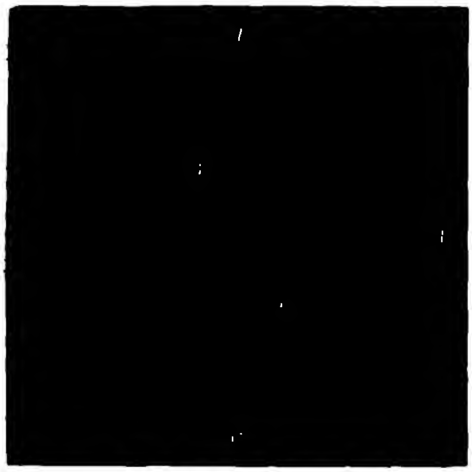


I. II III.

—The nitro-derivatives of phenolphthalein, by J. A Hall The author has prepared dinitro and tetranitro-phenolphthalein,

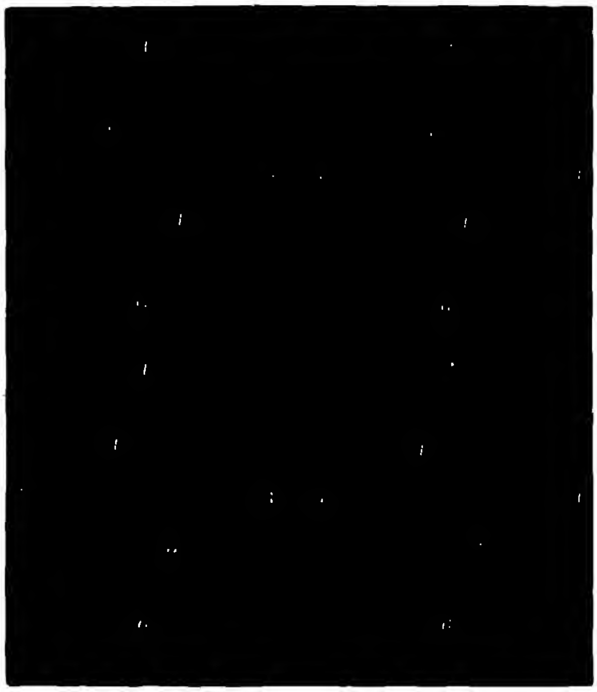
and describes their properties.—A method for the preparation of acetylene, by M. W. Travers. Calcium carbide may be prepared by heating a mixture of sodium, gas carbon, and calcium chloride for half an hour at bright redness in an iron bottle. The carbide thus obtained yields acetylene on treatment with water. 240 c.c., half the theoretical quantity, of acetylene is obtained for every gram of sodium used in the preparation of the carbide.

Mathematical Society, February 9.—Mr. A. B. Kempe, F.R.S., President, in the chair.—The following communications were made:—The Harmonics of a Ring, by Mr. W. D. Niven, F.R.S. This paper treats of the potential functions of an anchor ring, and explains how problems to which those functions are applicable may be solved for two coaxal rings. The proposition on which the method depends establishes that the ring harmonics of any degree may be derived from their predecessors of lower degree by simple differentiations with regard to the radius of the dipolar circle of the ring and the distance of a fixed point from the plane of this circle. Ultimately the harmonics depend upon the potential at any point due to a distribution on the circle either uniform or varying as a circular function of the arc. Now the potential due to such distribution on a circle B may readily be expressed in terms of the harmonics pertaining to a coaxal circle A, and hence any harmonic pertaining to B, and therefore any series of such harmonics, may be expressed in a series pertaining to A. In the latter form they are suitable for the application of surface conditions at any ring whose dipolar circle is A. The application worked out in the paper is the problem of the influence of two electrically charged coaxal rings upon one another. It is also shown how the same problem may be solved for a ring and sphere, symmetrically situated as regards the axis.—The group of thirty cubes composed by six differently coloured squares, by Major MacMahon, R.A., F.R.S. Selecting any one of the thirty cubes at pleasure it is possible to select eight of the remaining twenty-nine which in reference to the cube selected have a very peculiar and interesting

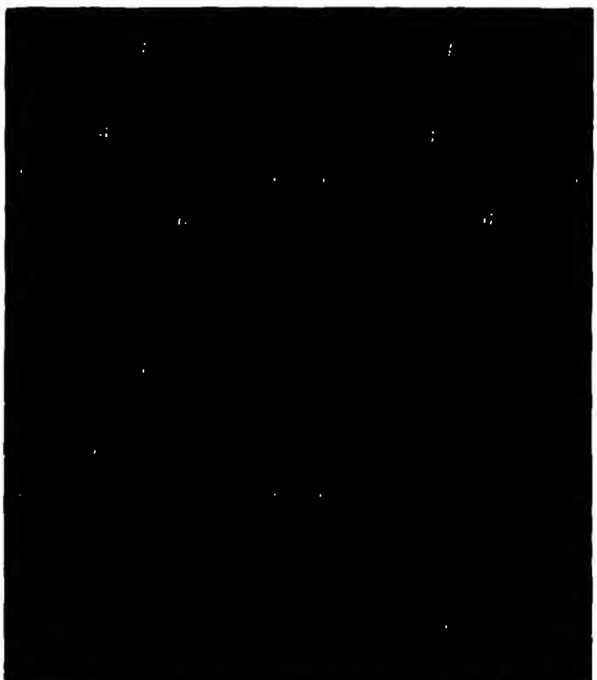


Selected Cube (transformed) diagonal 16 vertica

property. It is possible to form the eight cubes into a single cube in such wise that contiguous faces of the cubes are similarly coloured, and also so that the resulting cube has the appearance of the *selected* cube in regard to the colouring of its faces. To each cube of the thirty belong in this way eight other cubes, the selection of the eight cubes being unique. For the examination of this property the selected cube is transformed into an octahedron by joining the middle point of each face to the middle points of the adjacent faces; a regular octahedron with six differently coloured summits is thus obtained. Each triangular face is determined by three differently coloured summits, and exactly eight other octahedra are obtained by circular substitutions performed on the three colours which determine a face. In regard to the eight faces there are eight clock-wise and eight counter clock-wise substitutions, but only eight different octahedra can be obtained. These give the eight cubes associated with the selected cube. The eight cubes having been determined, the problem of forming them admits of just two solutions. One solution is—



Lower Four Cubes



Upper Four Cubes.

The other solution is obtained by interchanging clock-wise and counter clock-wise rotations of octahedral faces. Other interesting properties of these cubes are examined in the paper.

Geological Society, January 25.—W. H. Hudleston, F.R.S., President, in the chair.—The following communications were read:—On inclusions of tertiary granite in the Gabbro of the Cuilin Hills, Skye; and on the products resulting from the partial fusion of the acid by the basic rock, by Prof. J. W. Judd, F.R.S.—Anthracite and bituminous coal beds; an attempt to throw some light upon the manner in which anthracite was formed; or contributions towards the controversy regarding the formation of anthracite, by W. S. Gresley.

February 8.—W. H. Hudleston, F.R.S., President, in the chair.—The following communications were read:—Notes on some coast-sections at the Lizard. By Howard Fox and J. J. H. Teall, F.R.S. In the first part of the paper the authors describe a small portion of the west coast near Ogo Dour, where hornblende-schist and serpentine are exposed. As a result of the detailed mapping of the sloping face of the cliff, coupled with a microscopic examination of the rocks, they have arrived at the conclusion that the serpentine is part and parcel of the foliated series to which the hornblende schists belong, and that the apparent evidences of intrusion of serpentine into schist in that district are consequences of the folding and faulting to which the rocks have been subjected since the banding was produced. The interlamination of serpentine and schist is described, and also the effects of folding and faulting. Basic dykes, cutting both serpentine and schists, are clearly represented in the portion of the coast which has been mapped, and these locally pass into hornblende-schists, which can, however, be clearly distinguished from the schists of the country. The origin of the foliation in the dykes is discussed. The second part of the paper deals with a small portion of the coast east of the Lion Rock, Kynance. Here a small portion of the "granulitic series" is seen in juxta position with serpentine. The phenomena appear to indicate that the granulitic complex was intruded into the serpentine; but they may possibly be due to the fact that the two sets of rocks have been folded together while the granulitic complex was in a plastic condition, or to the intrusion of the serpentine into the complex while the latter was plastic.—On a radiolarian chert from Mullion Island, by Howard Fox and J. J. H. Teall. The main mass of Mullion Island is composed of a fine-grained "greenstone," which shows a peculiar globular or ellipsoidal structure, due to the presence of numerous curvilinear joints. Flat surfaces of this rock, such as are exposed in many places at the base of the cliff, remind one somewhat of the appearance of a lava of the "pahoehoe" type. The stratified rocks, which form only a very small portion of the island, consist of cherts, shales, and limestone. They occur as thin strips or sheets, and sometimes as detached lenticles within the igneous mass. The chert occurs in bands varying from a quarter of an inch to several inches in thickness, and is of radiolarian origin. The radiolaria are often clearly recognisable on the weathered surfaces of some of the beads, and the reticulated nature of the test may be observed by simply placing a portion of the weathered surface under the microscope. The authors describe the relations between the sedimentary and igneous rocks, and suggest that the peculiar phenomena may be due either to the injection of igneous material between the layers of the stratified series near the surface of the sea-bed while deposition was going on, or possibly to the flow of a submarine lava. The form of the radiolaria observed in the deposit, and also their mode of preservation, are described in an appendix by Dr. G. J. Hinde.—The reading of these papers was followed by a discussion, in which the President, Rev. Edwin Hill, Prof. Bonney, Dr. Hicks, Dr. Hind, and the authors took part.—Note on a radiolarian rock from Fanny Bay, Port Darwin, Australia, by G. J. Hinde. A specimen brought from Fanny Bay by Captain Moore, of H.M.S. *Penguin*, is of a dull white or yellowish tint, in places stained red. It has an earthy aspect, and is somewhat harder than chalk, but gives no action with hydrochloric acid. Microscopic sections show a fairly transparent groundmass, apparently amorphous silica, containing granules and subangular fragments up to ·075 millim. in diameter, some of which appear to be quartz. Besides this, the rock contains numerous radiolaria, and it is really a radiolarian earth intermediate in character between the Barbados earth and such cherts as those of the Ordovician strata of Southern Scotland. The details of the extent of the deposit and its relationship to other rocks of the area are not yet obtainable, though it is possible that a considerable thickness of rock mentioned by Mr. Tenison Woods as occurring in this area may also be of radiolarian origin. The author describes a species of *Cenellipsis*, two of *Astrophacus*, one of *Lithocyclia* (new), one of *Amphibrachium*, three of *Spongodiscus* (one new), four of *Spongolena* (all new), two of *Dictyomitra* (both new), one of *Lithocampe* (new), and two of *Stichocapsa* (both new). From these it is not practicable at present to determine the geological horizon of the rock; with one exception, all the genera represented occur from Palæozoic times to the present.—Notes on the geology of the district west of Caermarthen. Compiled from the notes of the late T. Roberts (communicated by Prof. T. McKenny Hughes, F.R.S.). To the east of the district around Haverfordwest, formerly described by the author and another, an anticlinal is found extending towards Caermarthen. The lowest beds discovered in this anticline are the *Tetragraptus*-beds of Arenig age, which have not hitherto been detected south of the St. David's area. They have yielded eight forms of graptolite, which have been determined by Prof. Lapworth. The higher beds correspond with those previously noticed in the district to the west; they are, in ascending order:—(1) Beds with "tuning-fork" *Didymograpti*, (2) Llandeilo limestone, (3) *Dicranograptus*-shales, (4) Robeston Wathen and Sholeshook limestones. Details of the geographical distribution of these and of their lithological and palæontological characters are given in the paper. After the reading of this paper Dr. Hicks said he felt sure he was expressing the feelings of the Fellows in referring to the serious loss which the Society had suffered by the death of Mr. T. Roberts, who certainly was one of the most promising palæontologists in this country. The important researches which he carried on, in conjunction with Mr. Marr, had made is now comparatively easy to understand some intricate and extensive districts in Pembrokeshire and Caermarthenshire, which previously were little more than blanks on the geological map.

February 17.—Anniversary Meeting.—The medals and funds were awarded as follows:—The Wollaston medal to Prof. N. S. Maskelyne, F.R.S.; Murchison medal to the Rev. O. Fisher; Lyell medal to Mr. E. T. Newton; and the Bigsby medal to Prof. W. J. Sollas, F.R.S.; the balance of the proceeds of the Wollaston fund to Mr. J. G. Goodchild; that of the Murchison fund to Mr. G. J. Williams; and that of the Lyell fund to Miss C. A. Raisin and Mr. A. N. Leeds. The following is the list of officers and council elected at the meeting:—President: W. H. Hudleston, F.R.S. Vice-Presidents: Sir A. Geikie, F.R.S., G. J. Hinde, Prof. J. W. Judd, F.R.S., H. Woodward, F.R.S. Secretaries: J. E. Marr, F.R.S., J. J. H. Teall, F.R.S. Foreign Secretary: J. W. Hulke, F.R.S. Treasurer: Prof. T. Wiltshire. Prof. J. F. Blake, Prof. T. G. Bonney, F.R.S., R. Etheridge, F.R.S., Sir A. Geikie, F.R.S., Prof. A. H. Green, F.R.S., Alfred Harker, H. Hicks, F.R.S., G. J. Hinde, T. V. Holmes, W. H. Hudleston, F.R.S., J. W. Hulke, F.R.S., Prof. J. W. Judd, F.R.S., R. Lydekker, Lieut.-General C. A. McMahon, J. E. Marr, F.R.S., H. W. Monckton, Clement Reid, F. Rutley, J. J. H. Teall, F.R.S., Prof. T. Wiltshire, Rev. H. H. Winwood, H. Woodward, F.R.S., H. B. Woodward. The presidential address dealt with some recent work of the Geological Society, the subjects ranging over a period of six or seven years. These embraced Pleistocene geology, theories in connection with Glaciation, Tertiary, Cretaceous, Jurassic, and Permo-Triassic geology. It further mentions that the number of papers on Pleistocene geology has been very considerable, and many of them relate to the south east and the south of England; those relating to Central England and South Wales were fewer in number, whilst the north had furnished but few papers. The great memoir on the Westleton Beds had provided much material for consideration; that portion relating to the Southern Drift being especially interesting. Reference was made to a paper on Pleistocene succession in the Trent basin as forming a fitting introduction to the fascinating problems connected with the North Wales border on the one side and with Flamborough Head on the other. From Scotland notice was taken of some supplementary remarks on the paralled roads of Glen Roy. Speculation as to the evidence of a palæozoic ice age, the date and duration of the Pleistocene glacial period, and a notice on misconceptions regarding the evidence of former glacial periods were also discussed. The Tertiary Geology of the London and Hampshire basins was considered, more especially in relation to the Upper Eocene, or Bartons, and their probable equivalents in West Surrey. Under this heading, also, comes the Geology of Barbados, since the oceanic deposits in that island were held to be of late Tertiary age. These interesting discoveries were reviewed

at some length, and the results compared with tables in the recently issued "*Challenger* Reports" In Upper Cretaceous Geology the phosphatic deposits at Ciply and Taplow were noticed, and also the important correlations of the basement-beds in Norfolk, Lincolnshire, and East Yorkshire The Lower Cretaceous beds at Specton next passed under review, more especially in connection with their somewhat difficult palæontology and possible equivalents in Eastern Europe It then went on to state that our knowledge of the Upper Jurassics of the East of England had of late years received considerable additions and important correlations between our Upper Jurassics generally, and their equivalent on the Jura had been effected, that the inferior Oolite and the Lias boundary had come in for their share of attention, whilst a determined attempt had been made to refer a portion of the red rocks of South Devon to the Permian

PARIS

Academy of Sciences, February 13 —M de Lacaze-Duthiers in the chair.—On an invariant number in the theory of algebraic surfaces, by M Emile Picard —Study of the Cañon Diablo meteorite, by M Henri Moissan The composition of the meteorite is very variable from point to point In the fragments examined the percentage of iron varied from 91 09 to 95 06, and that of nickel from 1 08 to 7 05 Diamonds were also found, both transparent and black, and a brown form of carbon of feeble density The largest diamond measured 0 7 mm by 0 3 mm It had a yellow tint and a rough surface, and was transparent to light —On the meteoric iron of Cañon Diablo, by M C Friedel A small quantity of a silver-white fragile compound occurring in the meteorite in the form of plates disseminated through the nickeliferous iron and accompanied by schreibersite, was isolated, and its composition found to correspond to the probable formula Fe_6S The mixtures of ordinary carbon, graphite, and diamond were found chiefly associated with nodules of yellow troilite —On the presence of graphite, carbonado, and microscopic diamonds in the blue earth of the Cape, by M Henri Moissan. After repeated and lengthy treatment with boiling sulphuric and hydrofluoric acids, 250 gr of blue earth left a residue weighing only 0 094 mgr. In this residue brilliant hexagonal crystals of graphite were found, giving rise, when treated with potassium chlorate, to a graphitic oxide of a colour passing from green to yellow Another species of graphite was also isolated which, when treated with H_2SO_4 at 200° C, swelled up considerably and dissolved Its artificial preparation will be described in a subsequent paper The portions of the residue unaffected by potassium chlorate and heavier than methylene iodide (density 3 4) comprised an amber-coloured mass, black diamonds, microscopic true diamonds, and small transparent crystals in form of elongated prisms, which did not burn in oxygen and were not fluorescent in violet light The first, which contains a large proportion of iron, and the last, which contains silica, can be destroyed by treatment with fused potassium bisulphate and then with hydrofluoric and sulphuric acids The blue earth, which was taken from the Old de Beers Mine, thus contained all the carbon compounds found in the iron matrix employed for their artificial production —The clasmatocytes, the fixed cellules of the connective tissue, and the pus globules, by M L Ranvier In an inflamed tissue the clasmatocytes and leucocytes are the only ones which give rise to purulent globules, the latter being, in fact, mortified lymphatic cellules —Glycosic expenditure attendant upon nutritive movement in hyperglycemia and hypoglycemia brought about experimentally, consequences bearing upon the immediate cause of diabetes and other deviations of glycemic function, by MM A Chauveau and Kaufmann —Observations of Holmes's comet made with the *equatorial coudé* (0 32 m) of the Lyon Observatory, by M G Le Cadet —On an explicit form of the addition formulæ of the most general hyperelliptic functions, by M. F de Salvert —On the laws of reciprocity and the sub-groups of the arithmetical group, by M. X. Stouff —Experiments on overflowed weirs, by M H Bazin.—On the fringes of caustics, by M J Macé de Lépinay —On a phenomenon of apparent reflection at the surface of the clouds, by M. C. Maltézos —On the electric figures produced at the surface of crystallised bodies, by M Paul Jannetaz If the face of a crystal be covered with matter consisting of light and small grains, such as lycopodium seed or talc powder, and an electric discharge passed into the face through a point outside it, certain figures are formed, many of which were investigated by Wiedemann and Senarmont Very regular ellipses were obtained by M. Jannetaz by passing a series of discharges from an electrostatic machine or an induction coil The orientation of the major axes of the ellipses was observed for a large number of minerals. In most cases this axis was perpendicular to the direction of maximum conductivity for heat. In the case of a well defined single cleavage, such as that of mica, talc, a block of wood, the cut edge of a book, or a schistose rock, the major axis was perpendicular to the plane of cleavage. The point need not touch the plate Figures were obtained on a plate of gypsum strewn with lycopodium powder, and charged from beneath. Positive and negative sparks show the same effect —Action of temperature on the rotatory power of liquids, by M Albert Colson —Density of nitrogen dioxide, by M A Leduc —Considerations on the genesis of the diamond, by M J Werth —On the chlorine derivatives of the propylamines, the benzylamines, aniline and paratoluidine, by M A Berg.—On dipropylcyanamide and dipropylcarbodiimide, by M F Chancel —Survival after section of the two vagi nerves, by M C Vanlair.—On the internal pericycle, by M Léon Flot —On a modification to be applied to the construction of bottles designed to collect specimens of deep waters, by M J Thoulet The compressibility of water is such that one litre, collected at a depth of 8000 m below sea-level, would expand by 35 cc when the bottle was opened at the surface Such bottles may therefore be constructed of thin sheet copper or other metal allowing an expansion of thirty-five parts in 10,000 —Lines of structure in the Winnebago County meteorite and some others, by Mr H A Newton —On a meteorite observed at Newhaven (Connecticut), by Mr H A Newton

MODERN OPTICS AND THE MICROSCOPE

The Microscope its Construction and Management Including Technique, Photomicrography, and the past and future of the Microscope By Dr Henri van Heurck, &c. English edition re-edited and augmented by the author from the fourth French edition, and translated by Wynne E Baxter, F R M S, F G S (London Crosby Lockwood and Son, 1893)

THIS is a handsome, even a luxurious, book It is beautifully printed on highly-finished paper, and with a margin ample enough to satisfy the most exacting connoisseur The illustrations are clearly produced, the binding is admirable, and after a careful comparison with the last French edition, we do not hesitate to say that the translation is as felicitous as it is accurate

Its author has aimed apparently at an elementary treatise on the microscope, which is nevertheless intended to cover almost the entire field involved in its history, production, and use The difficulties of such a task are not a few To be elementary and thoroughly popular up to a limit, very sharply defined, and then to lead on those who choose to follow into the deeper aspects of this many-sided subject, is at once practical and natural The optics of the modern microscope are the possession of the specialist. Abbe himself has failed to make them accessible to and understanded by any but those educationally equipped Hence the constant misunderstanding of the fundamental principles of the Diffraction Theory and its related applications so frequently manifest even where the subject is supposed to be more or less familiar

As might have been readily supposed, the author of this treatise has given evidence of skill in the presentation of the main points of elementary optics, it is, however, clearness and conciseness, not originality, that is to be noticed. The illustrations are those familiar to English text-books for the last quarter of a century, and the diffraction theory has in no way been simplified to the reader of an elementary treatise by that most efficient of all elementary modes of imparting ideas on more or less abstruse subjects, viz carefully devised and well-explained diagrams

Considering the object of this treatise, viz the impartation of knowledge to those not mathematically prepared to follow it in that direction, by giving a concise, clear, and comprehensive view of the meaning and application of the diffraction theory of microscopic vision, the transition from the first to the second chapter will be so abrupt and unlinked as to leave the elementary reader practically in the dark. The chapter on "The Theory of Microscopic Vision" is unexceptional so far as it goes. It cannot be other, it is Prof Abbe's, but, in a treatise claiming to maintain its elementary character more completely than any other similar work which covers so wide a range this is surely not enough.

The diffraction theory of vision is introduced to the tyro with no explanation of what diffraction is, and with no illustration of its action until he is plunged *in medias res* in Abbe's application of it to the profoundly important and inestimably valuable theory itself The "elementary" character of this is at least questionable Beyond this that most important factor in the diffraction theory in its practical application, Numerical Aperture, is wholly without explanation, save such as arises from its technical introduction and employment, but there are few points on which it is more important that an elementary student should be more clearly instructed, and there are few that lend themselves more to efficient diagrammatic presentation In the same relation it may be noted that the very essential formula $n \sin u$—expressing the general relation discovered by Abbe between the pencil of light admitted into the front of the objective, and that emerging from the back lens of the same, which is such that the ratio of the semi-diameter of the emergent pencil to the focal length of the objective could be expressed by the sine of half the angle of aperture (u) multiplied by the refractive index of the medium (n) in front of the objective or $n \sin u$—but this is a German mathematical formula, and its English equivalent is $\mu \sin \phi$, and although the German form of symbol is employed in England, and thoroughly understood by mathematicians, those who are entering for the first time upon a study of this difficult subject, and therefore unaccustomed to the mathematical formulæ employed, might readily fall into confusion, seeing that the "elementary" source of their information leaves them without a hint on the subject

Another serious defect, as we believe, in this "elementary" presentation of the diffraction theory of microscopic vision is the absence of an easy explanation of the *photometrical* equivalent of different apertures. Certainly it is not of the essence of the problem, but it is just one of those points which in a very marked and instructive manner illustrate the meaning and value of numerical aperture as such, and for elementary exposition this must be of importance Thus, if two circles be taken to represent the backs of two objectives of the same power but of different apertures, and the radius of one be twice that of the other, then each radius will represent the angle $n \sin u$ But because the areas of these circles are to each other in the proportion of the squares of their radii, it follows that if each radius be designated by $n \sin u$, the area of the lesser circle will be to the area of the greater circle as the square of the radius of the former is to the square of the radius of the latter Hence the area of the greater circle will be four times as great as that of the lesser, which teaches that since the numerical aperture of one objective is twice as great as that of another its illuminating power will be *four times* as great—a most important incidental and explanatory *raison d'être* for great N A.

In this connection we notice what is certainly not easily explicable as an exposition of the details of Abbe's great theory. On page 56 of "The Microscope" Dr Van Heurck almost incidentally states the very important fact that "Prof. Abbe has satisfactorily established the fact that a certain relation must exist between magnification and angular (?) aperture." This is undoubtedly one of the most important demonstrations of the theory Great numerical apertures have proved of untold value to the competent student of minute details, by opening up structures that mere amplification must have left for ever impenetrable. But that does not annul the import-

ance of small apertures Low amplifications are as useful in their own department as high ones, and to put great apertures to lower magnifying powers than such magnifying power warrants is to sin against the elementary principles of the Abbe theory of vision And on the other hand, wide apertures can never be utilised unless there is a concurrent and suitable linear amplification of the image which is competent to exhibit to the eye the smallest dimensions which are by optical law within the reach of such apertures

Thus it follows that great amplification will be useless with small apertures If the power be deficient the aperture will not avail, if the aperture be wanting nothing is gained by high power The law is, "Employ the full aperture suitable to the power used" In Abbe's words, "A proper economy of aperture is of equal importance with economy of power." [1]

Taking these facts, then, which are apparently recognised by Dr Van Heurck, it is very remarkable to find on page 49, in a discussion of the "screw threads" or gauges employed by the makers of microscopes, that the general value of the English gauge is admitted, but it is added, "The English thread is not, however, all that we have to say on this matter In America the *American thread* is also employed, which is considerably greater, and admits the use of lenses with a much larger diameter, *and thus offers certain advantages* In the first place, the larger the lens the easier it is to make, and consequently the real curvatures approach closer to the calculated curvatures, then the larger the lens the more luminous rays it admits, and this in photography is not to be despised"

To our judgment this statement is a contradiction of the admission made on page 49, quoted above

The enlargement of the screw for the purpose of putting in larger back lenses to objective combinations was first mooted in America in 1879,[2] when "Mr Bullock urged the desirability of adopting a uniform objective screw of larger size than the Society screw now in use (1879), as being essential to the efficacy of *low power lenses of high angle*"

This "American gauge" was subsequently introduced and known as the "Butterfield gauge of screw for objectives." [3]

Now, we must remember the date of the introduction of this large gauge for objectives, and its relation to the introduction of the apochromatic system of lenses We must further remember that the purpose of its adoption was to permit the introduction of larger back lenses than the Society gauge would suffer into an objective combination This meant giving relatively great apertures to lower powers But this, carried beyond a certain limit, violated a fundamental law of Abbe's theory[4] Now it is said that these larger lenses are easier to make (!) and approach more nearly to the calculated curves. But in truth objectives with wide apertures which are low powers, and must therefore have large backs, are most difficult lenses to produce It was, in fact, to escape the difficulty of giving lower powers larger angles that opticians of the first rank always designated their objectives as of lower magnifying power than they really were They in fact made a $\frac{2}{3}$rds a $\frac{1}{2}$, a $\frac{1}{2}$ a $\frac{4}{10}$ths; a $\frac{4}{10}$ths a $\frac{1}{4}$, a $\frac{1}{4}$ a $\frac{1}{5}$, and so on

Since Butterfield's gauge was introduced, long before the days of apochromatism, that is when our ignorance allowed us to over-aperture our low magnifying powers, it was tolerable, because it was evidence of experimental effort to improve the capacity of our lenses But to day *with* the society screw we are easily provided with a series beginning with a 1 inch objective of 3, and a $\frac{1}{2}$ inch objective of 65 N A., and we may venture to think that these are the highest ratios of aperture to power that will be accomplished for many a day, and therefore the highest ratios allowable by the Abbe theory of vision, which we now know, at least in this point, to be an enunciation of the established laws of optics

Moreover, *these* lenses are really difficult to make, with their back lenses easily placed within the diameter of the Society screw A high ratio of aperture to power always involves great expense in production, and therefore we find that the *low-priced* oil immersions of this immediate time are $\frac{1}{12}$ths and $\frac{1}{8}$ths, not objectives of low magnifying power, and for this reason only

Since then the Society screw is sufficient for more than double the apertures shown by Abbe to be in suitable ratio to the lower powers, we find it more than difficult to account for the teaching in a treatise intended to be essentially elementary, that the Butterfield screw gauge for objectives provides conditions which "offer certain advantages," when the supreme object of this part of the book is to enunciate fully the nature and qualities of oil immersion achromatic, and especially apochromatic, object glasses, by which we can get larger apertures with the society screw than in the old days of Butterfield's gauge could be got by the use of abnormal backs to objectives We find also that "penetrating power" is referred to in passing as one of the properties of object glasses (p 56), but since the diffraction theory of microscopic vision is associated with a special interpretation of what this means, and since it is to Prof Abbe that we are indebted for placing this hitherto obscure matter on a sound, scientific basis, it somewhat disappoints the reader to find no allusion whatever to the valuable work done on this subject, nor any elementary endeavour to explain the great truth that the actual depth of vision must always be the exact sum of the accommodation depth of the eye and the focal depth of the objective But there are few matters of more practical importance or that lend themselves more to simple exposition

In a treatise purporting to be essentially for the beginner we confess to disappointment concerning the instructions as to the "choice of a microscope" What is needed is that the tyro should know the *essentials* of the instrument, the points in it that are of indispensable importance, and a clear account of the manner in which these may—by the uninitiated—be seen to be of inferior or acceptable workmanship The reader is not even informed that in so important a matter as the *fine adjustment* there is a different value to be attached to several entirely different methods by which this function of the microscope is performed The bar and lever movement, essentially the best in principle and practice, is only referred to as existing, in the index, which is thus

1 J R M S., ser ii vol ii p 304
2 *American Naturalist* vol xiii. p. 60.
3 J R M S, ser ii vol i. p. 301
4 *Ibid*, vol ii p 304

made to serve as a kind of glossary, and even more remarkable is the fact that the patent lever fine adjustment of Swift and Son, the only fine adjustment which, in our judgment, makes the "Jackson Model" microscope (which Dr Van Heurck evidently affects) at all a practicable instrument, is treated in the same way So indeed is Campbell's differential screw, and the highest commendation is given to the form adopted in the author's own model No doubt in its present form it is relieved of many defects incident to the form of fine adjustment to which it belongs, but it must be remembered that we are told that each of the divisions of the milled head of this fine adjustment corresponds to the $\frac{1}{1000}$th of a millimetre Yet the screw which gives this fine result has to lift the whole "body" of the instrument In the lever fine adjustments only a nose-piece is lifted, having an inconsiderable weight, and producing in practice no friction, and to this the objective is attached, it certainly appears but reasonable, as it has proved in practice to workers who have employed the several methods for continuous years, that the "wear and tear" upon so fine a screw to which such heavy work is given does not contribute to permanent steadiness, or in constant work, to continued accuracy

In fact, after careful study of the microscope specialised in this treatise, it is difficult to discover anything really new or distinctive in it save the bringing of the fine adjustment pinion of the sub-stage above the level of the principal stage The value of this may be variously assessed, but it has the plain disadvantage of preventing the complete rotation of the principal stage, and it may be doubted if it has any advantage which will compensate for this

There is little, if anything, to enable the reader to distinguish as to the practical value of one form of stand as compared with another, and yet there can be no greater divergence in form than that between the Continental stand on the one hand with its dead weight to produce steadiness, and the two English models known as the Ross and Jackson models respectively on the other What distinguishes them, in what either of them has superiority over the other, and wherein in any of them what is essential to a first-rate working microscope, is nowhere discussed

It is true that the models of many makers are presented and beautifully printed, but many of these are not printed in these pages as revealing essential differences important for the reader to observe, but they are placed amongst others simply as the productions, with slight variations, of the same instruments by different makers We cannot but believe that if some plain directions had been given as to the essentials of a good microscope, and the principal models passed in review showing their conformity or otherwise to these requirements, the "elementary" object of the book would have been more fully accomplished, and the tyro more fully aided in the "choice of a microscope"

Dr Van Heurck has shown his practical knowledge of the microscope as a manipulator in many ways, in this book, but perhaps this is nowhere more fully seen than in his full appreciation of the *condenser* as an indispensable instrument in bringing out the finest optical possibilities of the most perfectly constructed object glasses His book may be said to be alone amongst continental treatises on the microscope in this respect It has been by very tardy steps that the continental makers, or the continental microscopists, have learned to appreciate the immense importance of a condenser in causing optical combinations to give their highest results It is but recently that so leading a firm as Zeiss has yielded on this point and produced condensers The first was chromatic, and, as a consequence, proportionately unsatisfactory Then came the most useful achromatic form of Abbe But we are glad to observe that Van Heurck recognises that the *apochromatic* immersion condenser of Powell "is the most perfect condenser which exists at present" (p 85) It is inevitable that with apochromatic objectives it should be We cannot possibly see how the splendid objectives on apochromatic principles can give their finest results unless they are illuminated by an apparatus which is not only as perfect in workmanship, but of as great a numerical aperture, and with as complete corrections as the objective which is collecting the light and forming the image of the object the condenser is illuminating

And for this reason, while we admit fully that the plate of photo-micrographs produced in this and other volumes by the very exceptional skill of Dr Van Heurck with the most remarkable object glass which the manipulative skill of man has yet produced, viz the 2 5 mm with N A 1 63, is a monument to his manipulative ability, we still contend that he worked under difficulties of no small importance The only condenser provided for this lens by the great firm which produce it, is one which of necessity has a flint front, but is as wholly uncorrected as the glasses used by Hooke or Bonanni!

Now if it be important to use an apochromatic condenser at all, how much more important to use it on such a lens, with such an aperture and such exquisitely refined corrections This objective has never yet had its best power revealed, because its illumination has been always a counteraction of its own refinements

We are surprised that in manipulation the tyro is recommended in this treatise to focus *down* upon the object first, of course with great care, and then to find the actual focal point by withdrawing the tube by either coarse or fine adjustment A far more elegant and safe method is certainly adopted, and we doubt the preference expressed for daylight as the best constant source of illumination It is uncertain and always variable and more refractory than the edge of a good lamp-flame, unless we need a monochromatic ray from a sunbeam

At the close of the book there is a communication which had appeared before in the Journ Roy Micro Soc, from Dr S Czapski, which gives a suggestion for the possible enlargement of the practical N A. of homogeneous object-glasses, which makes an advance to 2 0 possible without the employment of the dense flint and highly refractive media needed by the lens spoken of above In fact it is plain that true monochromatic light may increase a N A of 1 40 to 1 75

There is a chapter on photomicrography which has the value that is inevitable, coming as it does from one of the most practised and efficient workers, still it can hardly be expected to be exhaustive, and every practical photomicrographer has, and adopts as most perfect, his

own methods, and as none will ever become photomicrographers who have not some ingenuity and enthusiasm, it is only needful that they be set to work, and they will undoubtedly find *their own* "best methods"

This treatise is too general to expect from it more than useful and suggestive hints on the subject of the preparation and mounting of objects, and the same may be said as to the history of the microscope, which is nevertheless given in an interesting and useful manner The book will undoubtedly attract many readers, and it will afford help to many who are seeking it, but we respectfully doubt whether it will enable the elementary reader to fully follow the diffraction theory of microscopic vision, so as to be able to understand its application to the wide range of subjects supposed to be dealt with from that point of view by this sumptuous treatise

W H DALLINGER

A UNIVERSITY EXTENSION MANUAL

The Earth's History an Introduction to Modern Geology By R D Roberts, M A (Camb), D Sc (Lond) With Coloured Maps and Illustrations (London John Murray, 1893)

THIS is not a large book, and a slightly less ambitious title might have been more appropriate Certainly it is an introduction to the study of modern geology rather than a history of the earth, for the latter is regarded from a limited point of view But from the page preceding the frontispiece it appears that the volume is one of a series of "University Extension Manuals" It partakes, therefore, of the advantages and disadvantages of this method of disseminating knowledge

The topics treated by Dr Roberts are the progress of geological thought the beginnings of the earth's history the modifications of its surface due to forces destructive and reproductive. the movements of its crust, including the action of volcanoes. Finally he deals with the formation of rock masses, and attempts to give—though of necessity this subject is very imperfectly treated—some idea of the evolution of the British Islands.
